Pharmacia Fine Chemicals
Pharmacia Fine Chemicals AB Uppsala, Sweden
Lot No. 3792
Wet bead diameter: 40—105 µm

Sephacryl®

the different medium for gel filtration

- Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.
- Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

applied excellence

Advanced techniques in routine use at The Radiochemical Centre

Described below are just two examples of the many up-to-date techniques, which have been pioneered or applied for routine use at The Radiochemical Centre. These developments are part of our constant endeavour to maintain our position at the forefront of the specialised field of tracer methodology, so that we can continue our supply of radiochemicals of the highest quality and technical specifications.

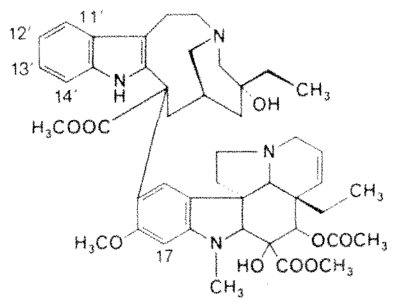
Distribution of labelling in tritium compounds

Modern techniques for the production of tritiated compounds are more sophisticated than those used in the early days of tritium labelling, and produce compounds labelled in specific positions rather than generally labelled. Nevertheless, it is necessary for many tracer applications of tritium compounds to know the *precise* position and configuration of the tritium labels. Traditional chemical methods of doing this are tedious and time consuming and subject to considerable error, and so the routine supply of such information has until recently not been possible.

The Radiochemical Centre, in collaboration with the University of Surrey, has developed over the past eight years the technique of tritium nuclear magnetic resonance (tnmr) spectroscopy for this purpose. This method is much quicker and more accurate than the traditional chemical or biochemical methods for determining distribution of tritium labelling.

It is now used routinely to establish the distribution of tritium labelling produced by the usual methods of tritiation employed at The Radiochemical Centre. We supply accurate details as to the position and configuration of the tritium labels for an increasing number of our labelled compounds.

A number of examples are given below:



[G-^{3}H]VINBLASTINE
Code TRK.507
17 .... 44% 11′ 8%
12′,13′ ..... 46% 14′ 2%

[1β, 2β(n)-^{3}H]TESTOSTERONE
Code TRK.162
1α ..... 5.9% 2α 8.2%
1β ..... 46.0% 2β 39.9%

[6-^{3}H]BENZO[a]PYRENE
Code TRK.501
6 ..... >95% 1 ..... <5%

D-[2-^{3}H]GLUCOSE
Code TRK.361
2(α) ..... 40% 2(β) 60%

L-[3,4(n)-^{3}H]VALINE
Code TRA/K.533
2 .... 8% 4 ..... 64%
3 .... 28%

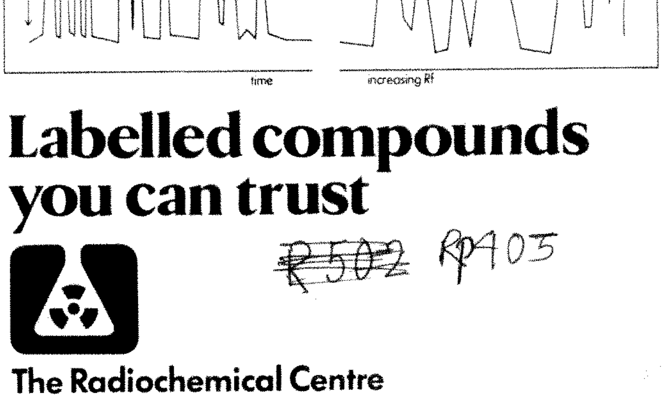
High performance liquid chromatography (HPLC)

This relatively new development of column chromatography is carried out using high efficiency microparticulate column packings of closely defined size.

Chromatography is carried out under pressure to ensure good flow rates and reduce diffusion of separated compounds. Dead volumes are kept to an absolute minimum. The result is that many separations can be carried out more quickly and with better resolution than with previously used chromatographic methods such as thin-layer chromatography or conventional column chromatography.

Work aimed at developing the applications of this method to radiolabelled compound separations is still in progress, but The Radiochemical Centre is already using the technique in many of its production processes, and in analytical applications. The result is purer compounds for the customer and greater efficiency of working.

The example illustrated below illustrates the clear superiority of HPLC when used as an analytical tool. The mixture used comprised the tritium labelled mono-, di- and triphosphates of adenosine, cytidine, guanosine and uridine, and all are clearly separated in the HPLC system.



Labelled compounds you can trust

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258**,1 (1975) and **264**, v, 11 Nov. (1976)

Nature has appointed an American Publisher, Robert Ubell.

For more than a century, *Nature* has served the international scientific community across all its disciplines. We have decided further to develop that service.

Nature is published in England, where it was born in 1869. But as scientific excellence has spread and multiplied, so has the input to *Nature* and the sales of it. In 1978 over a third of our print run is despatched to North America; less than a fifth stays in Britain.

In February 1970, we opened an office in the United States. It is time, now, to expand that presence with the appointment of an American Publisher.

In February 1979, Mr Ubell, at present Editor of *The Sciences* (New York Academy of Sciences) and previously Vice-President and Editor in Chief of Plenum Publishing Corporation, takes up this appointment. Based in the United States, he will be working closely with our publishing team in London; indeed he will be part of it.

Dr Stuart Sharrock, for the past two years Physical Sciences Editor of *Nature*, takes up a new post as Publishing Manager of the Learned Journals Division of Macmillan Journals Ltd on 1 January 1979. He will be replaced by Dr Konrad Guettler as Physical Sciences Editor.

How Britain runs its science

This highly successful chart, which appeared in Nature 28 August 1975 (but is still much requested and much referred to), has now been completely revised and updated to include all major changes in the personnel and administration of British science.

Measuring approximately 2′ x 3′ and containing black-and-white illustrations of prominent figures, copies of this chart are now available at 75p (UK), US $1.50 (Rest of World).

Payment may be made in any currency at the prevailing exchange rate. Cheques should be made payable to Macmillan Journals Ltd. Prices include postage and packing.

To order please complete the coupon below, or write, enclosing the correct remittance.

UNCSTD's Year

1979 is the year of UNCSTD, the United Nations Conference on Science and Technology for Development, which will meet in Vienna for two weeks during August. In this past year almost every nation with any interest in science and technology has compiled a national paper representing its point of view, and well over 100 documents, many running to 50 pages or more, now reside in the UNCSTD secretariat at the UN headquarters in New York. During these next few months the secretariat will have the unenviable task of distilling an immense amount of fact and opinion into some sort of agenda for Vienna. In the meantime subconferences in preparation for the main meeting continue unabated; in January for instance there will be meetings in Tallin in the Soviet Union and in Singapore (organised by the International Council of Scientific Unions).

Is the conference going to work out satisfactorily? What, even, do we mean by a 'satisfactory' conference? Presumably one that breaks up in fist fights or that falls apart over issues peripheral to the main themes would be deemed unsatisfactory. So too, although this view is not universally shared, would be one in which no voices were raised, no feeling engendered, no criticism voiced. Between these two poles there is much scope and it will depend largely on the leadership that the UNCSTD secretariat gives whether much of value emerges. The outcome of the labours of thousands who have contributed in one way or another to conference documents is, in the strange system in which we work, ultimately dependent on a handful of people at headquarters. In the past year such news that has filtered out has suggested quite strongly that all is not well. If relations are not all they ought to be, then this may well be excessively occupying the time of those who would be better employed in making the conference work.

But what of the papers themselves? After all the very act of compiling national papers must have put some countries through a salutary exercise of asking questions, perhaps for the first time, about the relationship between science, technology and development. We expressed the hope a year ago that this exercise would not be confined to bureaucrats but would encompass as many scientists and technologists as possible, whilst recognising that the conference is not specifically about science and technology as such. It is pleasing to be able to note that if the preambles to papers are to be believed a widespread process of consultation, meetings and conferences has gone on in many developing countries. Developed countries, cautious about committing themselves to large new expenditures on major institutional change, have on the whole provided papers descriptive of what they can do and are prepared to do but which shy away from more general discussions of principles—some also show signs of having little involved people outside certain official circles. The British paper is a case in point; it is scrupulously accurate but the Overseas Development Ministry, which compiled it has not in any sense used the preparation of the document as an opportunity to get a national debate going.

The Vienna meeting could be an excellent opportunity for the world to evaluate very carefully just what is being and could be done in the field of science, technology and development. But for this to happen some very self-critical voices would need to be raised. Unfortunately those who attend are most likely to be representatives of government agencies and national science funding agencies with a natural concern for self-preservation. Even if the papers contain an element of self-criticism (and a few do, notably from the developing world), when it comes to the meeting itself it will take a very brave delegate to acknowledge publicly—and take the message back home—that national mechanisms for channelling science and technology into development are in need of overhaul. And yet this undoubtedly needs saying. In the developed world there is inadequate discussion about whether the level of scientific resources devoted to the developing world is appropriate and whether present organisations are making the best use of these resources. In the developing world national science bodies too often seem to get into the hands of scientists who steer the country's effort away from the immense complexities of development and towards the slightly less complex business of imitating Western science.

If the UNCSTD secretariat could make delegates ask fundamental questions about their own national efforts, that would be a real achievement. And if the organisers of the peripheral meetings in Vienna could reach out beyond official viewpoints and tap some of the more speculative feeling abroad, then the whole exercise could still be very worthwhile. □

Kenya leads the way in environmental planning

THE government of Kenya has started a systematic across-the-board environmental assessment of its entire development programme—the first national exercise of its kind in the Third World. Officials at the United Nations Environment Programme (UNEP) and the United Nations Development Programme (UNDP), both of which are assisting Kenya in executing the project, are enthusiastic about this project.

Its success should help UNDP to promote similar environmental assessment projects in other developing countries, where many policy makers continue to harbour the same mistrust towards the environmental debate that they displayed at the Stockholm conference in 1972. While many argue that environmental considerations are a luxury for Third World development planners, there are others who see in environmentalism a philosophy designed to retard the economic development of the Third World, particularly its industrial development.

The Kenyans are quite aware that there can be strong conflicts between environment and development. They are therefore looking for only limited but quite realistic results from their exercise. At the least, it should help to reduce those innumerable environmental problems that are often created because of simple oversights at the planning stage.

Kenya's Tana River development scheme, for instance, will create one of the biggest man-made lakes in Africa. The spread of irrigation carries the threat of schistosomiasis. Between disease and agricultural prosperity Kenya, like any other Third World country, would obviously choose the latter. However, an advance environmental assessment exercise would help to promote possible control measures right from the beginning. It would also remind project authorities that the labour force building the dam has to be provided with energy. Otherwise, merely because of this oversight, forests could get depleted, and the resulting soil erosion could lead to rapid silting of the new reservoir.

Environmentally bad siting of projects, like a chemical plant near a bird sanctuary, can be prevented quite easily with the help of such exercises. "To delay the starting of a paper mill after it has been built, neither helps the country nor the firm setting it up", explains George Muhoho, until recently head of Kenya's National Environment Secretariat (NES), the Kenyan agency co-ordinating the environment-development project.

In the past, the NES has conducted several studies on various individual projects and influenced government decisions. But the current exercise now provides it with a rare opportunity to develop a comprehensive and long-term approach to environmental planning in the country.

The final recommendations of the project may well strongly favour a high rate of industrial growth. The most pressing environmental issues in Kenya are those related to land-use. South of the Sahara, Kenya has the highest population growth rate. Kenya's population is expected to double within 20 years. At the moment, nearly 90% of Kenya's population lives in the rural areas earning its livelihood predominantly from agriculture. Unless a rapid transformation takes place in the occupational structure of the country and more people find jobs in industry, the pressure on the land could become too intense.

As increasingly marginal land is brought under cultivation, deforestation and desertification will increase. Encroachment on game parks could seriously affect wildlife conservation. By contrast, Kenya could simply forget about air pollution control until it has reached a far higher level of industrial development. A comprehensive environmental planning exercise could thus identify urgent development priorities and critical environmental issues as well.

An important aspect of the project is that it relies largely on local Kenyan expertise. The temptation to invite a UN mission consisting of Western experts to prepare a report on environmental problems was studiously avoided. Such an approach would have robbed the Kenyans of a chance to assess by themselves the environmental effects of what they were doing, and thus develop their own perspective on environment and development related issues. Moreover, even in the West, few people can really stake a claim to be an expert on environment-development planning.

To ensure the involvement of all available local expertise, and popular participation, the project is being executed in three phases. In the first phase, which was completed in August, 1978, five papers were prepared that surveyed major environmental problems in Kenya. These papers were then thrown open for discussions at a week-long meeting in July, 1978, attended by 11 senior Kenyan officials, including the Minister of Finance and Planning, and several permanent secretaries in the government. This meeting identified existing gaps in knowledge and possible policy alternatives. Finally, a steering committee for the rest of the project was formed consisting of the officials present at the meeting to enlist the active co-operation of all the ministries.

In the second phase, much more specialised studies on specific scientific, technical, legal and sociological issues are being conducted to find answers to the questions raised at the earlier meeting. To do these studies, local expertise will be drawn from wherever available—from official institutions to non-government organisations and universities. Foreign experts will be recruited only for highly technical subjects where no local expertise exists. Finally, in the third phase, to be completed by August, 1979, the final recommendations will be put together.

Bacteriologists lobby GMAG's first public meeting

Sir William Henderson: optimistic

A LOBBY for the exemption of experiments in which recombinant DNA techniques are used simply to rearrange the genes within *E. coli* and other bacteria made a strong protest against continuing control at GMAG's first public meeting last week.

GMAG, Britain's Genetic Manipulation Advisory Group, was fulfilling its promise to hold open meetings on its proposed new system for the risk assessment of recombinant DNA experiments (*Nature* **276,** 104; 1978).

The new chairman of GMAG, Sir William Henderson (above right), opened the meeting optimistically, saying that those who feel that GMAG's hand is too heavy "do not sufficiently allow for the depth of public interest, and how the composition of GMAG takes this into account". But all on GMAG, said Sir William "wish to improve the procedures and consult".

Those at the meeting, held on the last working day before Christmas (22 December), were mostly scientists. The consultation amounted largely to two protests from the floor: that the new scheme was difficult to operate in practice because of lack of sufficient knowledge; and that the re-arrangement of genes within a bacterium such as *E. coli* using recombinant DNA techniques (but not otherwise) must still legally be notified to the Health and safety Executive and then to GMAG, and must be carried out under Category I conditions.

These conditions, although the least stringent of GMAG's four categories of physical containment, are still more rigorous than normal laboratory practice and can mean that the laboratory has to be modified. This type of experiment has now been exempted from control under the proposed new NIH guidelines in the US, but hopes that the new proposals in the UK would automatically exempt these experiments have been disappointed.

Question after question from the floor drew an acknowledgment from Professor Mark Richmond of GMAG that the group would have to make a decision on this problem soon. John Maddox, one of GMAG's public interest representatives, defended the categorisation and notification of such experiments on political grounds. While accepting that the procedure for notification would be made simpler and easier, he took the view that public concern would be lessened if GMAG were seen to be controlling all experiments using recombinant DNA techniques, even though there might be scientific grounds for exemptions in certain cases.

From the floor Professor R. Pritchard warned that this type of apparent illogicality undermined the credibility of the whole notification procedure in the eyes of researchers and their local safety committees.

Nevertheless, the feeling of the meeting was that the new risk assessment scheme was more rational than previous guidelines. But its precise application worried people.

The most immediate problem is posed by the 'gaps' in biological knowledge which become apparent when a consistent attempt is made to calculate the risk of an experiment. For example, the causes of pathogenicity are not well understood, so one cannot estimate all the possible biological effects of a modified bacterium on the human body.

In cases like this Dr Sydney Brenner —who invented the scheme and was present at the meeting—falls back on averages. Of all known bacteria, what fraction are pathogenic? This fraction could be applied as the probability that any new bacterium were pathogenic.

Dr Peter Rigby of Imperial College, who according to Dr Brenner "has worked out a magnificent set of examples", raised the final issue: that all the calculation is in vain if the precise containment effectiveness of the four containment categories is unknown. Some claim the containment factor between categories I and IV to be 10^{12}; some 10^{8}. "It must be measured" said Dr Rigby, extracting a cautious commitment that GMAG act.

Eleanor Lawrence

UK health ann safety: £1,800 million bill

PREVENTION rather than cure, and hence research, is a major theme in the recently published annual reports of the UK's Health and Safety Commission (HSC) and Health and Safety Executive (HSE). The HSC's plans for the next five years, its report says, include epidemiological studies on populations at risk from hazardous substances; a major review of the risks to health from exposure to asbestos; the development of a policy for protecting people from the hazards of genetic engineering and working with dangerous pathogens; and research on the design safety of equipment in nuclear power reactors.

In the introduction to the HSE report John Locke, the HSE's Director General says that "research, the systematic collection and analysis of a wide range of data and the dissemination of information to all who need it" is the hallmark of the executive's efforts to reduce occupational hazards. He points out that the 16 million days lost in 1976 through accidents are estimated to have cost the country some £1,800 million. The "great majority of accidents could be prevented if simple precautions are taken" he says.

Over the past few years, the HSC's report says, there has been a reduction in the number of deaths from industrial accidents. Nevertheless, Mr Bill Simpson, Chairman of the commission, believes that "there is no room for complacency". Although the number of deaths has gone down, the number of notifiable accidents was 329,000 in 1977, 2,000 up on the previous year.

The commission's report also describes the preparation of draft regulations on the notification, and in some cases survey, of installations constituting a major hazard. It comments on the regulations laid before Parliament for the packaging and labelling of about 800 dangerous chemicals in common use and discusses its efforts to change the law which exempts government controlled institutions from prosecution under health and safety legislation.

The problem of the universities and health and safety is still under review by the executive according to John Locke. The HSE is still getting to know people in the universities (heads of departments, trade unionists etc.) and identifying those sections which may present special hazards to workers or the public. Locke feels that students are the main problem because generally they are not sufficiently well trained to work in hazardous environments.

Protests over Einstein statue

A PROPOSAL by the US National Academy of Sciences to erect a 21-foot statue of Albert Einstein in its Washington grounds has run into a storm of protest from members of both the academy itself and of the local Washington community.

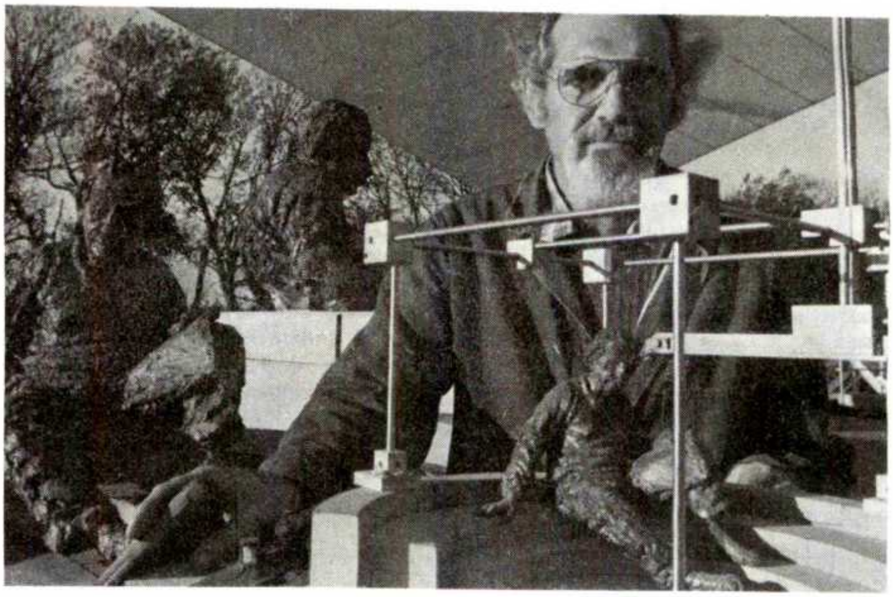
Several physicists have complained that at a time when basic science is being squeezed for funds, it is inappropriate for the academy to be seen spending $1.5 million on the statue, and that Einstein himself would have preferred the money to have been spent on some scientific endeavour.

Others have pointed out that Einstein repeatedly asked that he should not be treated as a cultural hero. And comments on the design of the statue in the local press have ranged from "a blunder of mediocrity" to "the latest disgrace to our city".

The decision to erect the statue as part of this year's centennial celebrations of Einstein's birth was announced two months ago by Dr Philip Handler, president of the academy. According to Dr Handler, the large size of the bronze statue—which together with its marble base will weigh 139 tons—represents that fact that Einstein was "a giant among men".

The sculpture is the work of artist Robert Berks, who sculpted a head of the physicist in 1953. He had previously proposed unsuccessfully a full-length statue to the Weizmann Institute in Israel, to Princeton University, and to the Smithsonian Institution in Washington.

The academy has written to all its members, as well as other members of the scientific and technical community, requesting financial support for the project. But while some have been pleased to contribute—over 2,000 contributions have so far been received—others are less happy.



Sculptor Robert Berks with models of the controversial statue

"There are a number of people here who almost hit the ceiling when they were asked to contribute to the statue. So far I have not heard a favourable word from anyone on the scheme," a physicist at one West coast university said last week.

Another complained that the decision to erect the statue had "simply arrived out of the blue", and that although the proposal had initially been put to and accepted by an annual meeting of the academy, there should have been wider discussion among members.

In Washington, opposition to the statue has been expressed mainly in the pages of the *Washington Post*. Following a critical article by one of the newspaper's contributors, a number of readers wrote in voicing objections.

Commenting on the large scale of the statue, for example, one correspondent wrote that "If anything concise may be said about Einstein's life, it is that he was a philosopher of mathematical precision and theoretical proportion". The *Post* itself joined in the fray with an editorial complaining that the statue "doesn't honour its subject", and suggesting that the academy should "start again".

A spokesman for the NAS said last week that the academy had not yet decided whether to reply to the criticism made in the *Post*, and pointed out that a large number of favourable comments about the statue—including its initial approval by Washington's Commission of Fine Arts—had been received.

David Dickson

AAAS to assist China with the popularisation of science

AN agreement opening the way to joint activities on the popularisation of science and on science education has been reached between the American Association for the Advancement of Science and the Scientific and Technical Association (STA) of the People's Republic of China.

The agreement, which is expected to lead to increasing co-operation at the nongovernmental level between the two organisations, was worked out during a visit to China last month by a 12-person delegation from the AAAS.

In particular, the agreement provides for a return visit by the Chinese to the US next spring, and for the AAAS to identify US specialists willing to visit China to lecture on topics specified by the STA.

Announcing these moves in Washington on the AAAS delegation's return, Mr Emilio Q. Daddario, chairman of the association's board of directors, said that various Chinese ministers had given their approval to such an agreement, and that President Carter's announcement of the normalisation of diplomatic relations between the two countries "cannot but help to make our agreement more meaningful."

Mr Daddario also said that the Chinese were contemplating sending a special misssion to the US to look at various ways in which science is "popularised". Such a visit might include talks with science journalists, and visits to science museums and technical information centres.

"During the Cultural Revolution there was a sense in China that science produces an intellectual elite. Now they want to make it clear to the masses that science has benefits for people, and that it is important that they should understand it", said Mr William Carey, executive officer of the AAAS.

"The Chinese want to get people in the streets, in the farms and in the factories to support the thrust towards modernisation in the fields of science and technology. And they have a very great appetite for US experts to go and give lectures, a method they are seizing upon to get a quick turn-around on their scientific efforts."

Mr Carey said that the Chinese had expressed interest in working with the AAAS on various aspects of science education, in particular the development of curricula for university and higher education.

University of California faces drastic cuts

Proposed budget reductions may force closure of whole campuses and medical schools, writes **John H. Douglas** from San Francisco

RESPONDING to strong popular sentiment against high levels of government spending, California governor Edmund G. Brown, Jr., has demanded that all state agencies submit a list of programmes that can be cut immediately in order to bring about a 10% reduction in next year's budget.

Such cuts could drastically affect the prestige and research capability of the 9-campus University of California, which accepts students from the top 12.5% of the state's high school graduates. More students, however, would be affected by reductions in the 19-campus State University and Colleges system, which accepts students from the top one-third of high school classes, and in the 106 state-supported Community Colleges, which presently are open to any resident 18 years of age or older.

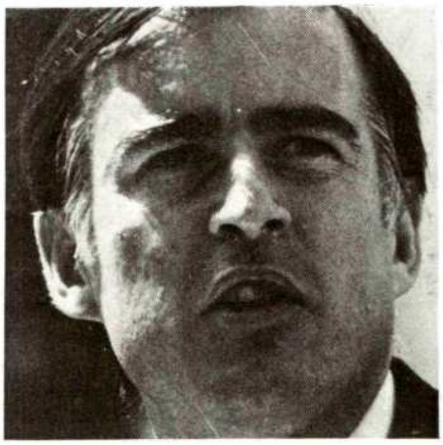
In a strongly worded reply to the governor's demands, University of California president David S. Saxon said flatly that spending reductions of this magnitude simply could not be accomplished by next year if the university were to honour its commitments to present students and to contracts with external agencies. Even to reduce the budget over the next three to five years, he said, would require closing a combination of campuses, medical schools and associated research institutes.

However, one of the factors cited by Governor Brown in defence of his proposed cuts is that during his past four year term the budget for the State University and Colleges has risen by 44.4% over the cost of living, although enrolment has dropped 2.6%. Such declines can be expected to continue, since a 25% reduction in the college-age population is expected over the next decade.

Saxon nevertheless warned the governor that to cut 10% (or about $77 million) in state support would translate into a much larger reduction in the overall university budget, since many programmes receive an equal amount of funding from other sources. Especially hard hit would be the science programmes that receive large research grants from the Federal government. "The number of jobs lost would be more than doubled", Saxon said.

To make matters even worse, the proposed reductions would come just at a time when the university has already suffered a $31 million cut in its proposed budget, following passage of Proposition 13 in this year's elections (which substantially reduced property taxes). And university employees did not receive any salary increases this year, putting them at the mercy of 8% inflation and setting the university a year behind many other institutions. Unless salary increases come soon, says Saxon, "our base would be so low that we would be unable to offer competitive salaries to any employees, and especially faculty, for the foreseeable future".

If major units of the University of California must be closed, speculation has centred on the vulnerability of the two smallest non-specialised campuses, at Riverside and Santa Cruz. The campuses suffered enrolment decreases this year of 5% and 3.5% respectively, compared to an increase in overall university enrolment of 1.5%. Riverside was upgraded from an agricultural institute and has never enjoyed the prestige of older campuses. Santa Cruz is remotely located and uses a controversial student evaluation system. Closing either unit would require special legislation, however.



Governor Brown : cuts all round

Other solutions under discussion would also require new legislation and, perhaps more important, the cooperation of the governor. Rather than cutting expenses, as directed, the university could be made more independent of state treasury funds by increasing student fees. California now supports the only system of higher education in the United States that is theoretically tuition free, although students pay about $700 a year in "fees". Increasing such fees by $100 a quarter (or imposing tuition of that amount) could raise nearly $35 million for the university. Proponents of this idea point out that more long-term loans are now available to middle class families than when the tuition-free system was originally set up. Raising admissions standards might also help relieve pressure on the university.

Population decreases and rising fees are likely to hit hardest at the Community Colleges, where competition for entrance is not so keen. Enrolment in normal credit courses declined 4% this year, although it was originally expected to rise 3%. And when new fees were added last fall to non-credit courses (which attract older students not working toward a degree), enrolment in such courses plunged 40%.

All of these problems are likely to come to a head next spring when the California legislature considers the state budget. The eventual outcome is likely to hinge on details of a political process that may seem quaint even by California's arcane standards. Although the universities and colleges have powerful friends in the legislature, the governor has authority to veto *specific* budget items and could thus eliminate individual programmes he dislikes. And, for the first time in this century, California's governor and lieutenant governor belong to different parties. The new Republican lieutenant governor, Mike Curb, has strongly hinted he will oppose Democrat Brown on the university issue. What this would mean remains unclear.

Finally, several legal questions remain unresolved. By custom, faculty tenure at the University of California has been considered to apply only on one campus. If campuses were eliminated, the future of tenured faculty would be cast into doubt, as would the university's reputation as a desirable institution with which to affiliate. Long-term research contracts between university institutes and Federal funding agencies would also be threatened.

In assessing the possible impact of the proposed budget cuts, some of the most vigorous and articulate support for the University of California has come from the president of a competing private institution: Richard W. Lyman of Stanford University. Calling the University of California system "the greatest publically supported university in the country", Lyman said: "Californians have gone to considerable lengths to try to protect this uniquely fine university from being converted into a mere arm of government. It would be a sad irony indeed if, in the effort to trim government down to defensible size, the university were to be damaged in ways that would require many years of painstaking work to correct, if indeed they could be remedied at all". □

0028–0836/79/0277—0005$01.00

news in brief

NASA abandons attempts to rescue Skylab: The US National Aeronautics and Space Administration announced last week that it was abandoning its efforts to prevent Skylab, the 85-ton space station last used by astronauts in 1974, from falling to earth sometime next autumn.

As a result, the vehicle is expected to break up on entering the earth's atmosphere, scattering between 400 and 500 pieces of metal over a path 4,000 miles long. Some of these will probably strike the earth's surface, but according to the agency "the probability of injury or damage is less than that from meteorites."

Initially planned to remain in orbit until 1983, when it could be reached from a standard space shuttle flight, concern about Skylab's fate arose earlier this year when it was realised that the vehicle was slowing down as a result of the extra drag caused by sun-spot activity, and thus beginning to fall back to earth earlier than anticipated.

NASA had hoped that it could maintain Skylab in orbit until a small booster rocket could be sent up on an early space shuttle mission to take it into a higher orbit. However, problems with Skylab's control equipment, as well as development problems with the space shuttle programme, led to NASA's decision—supported by President Carter—to call off the rescue attempt.

Carter expected to boost defence research and cut back biomedical research: A major increase in financial support for military research and development, and a reduction in funding for biomedical research, are expected to be included in the budget request for the financial year 1980 which President Carter will present to Congress on 22 January.

The research and development budget is therefore expected to reflect the main thrusts of the overall budget, with reductions in social welfare programmes in an attempt to keep the budget deficit below $30 billion, but an increase in defence spending.

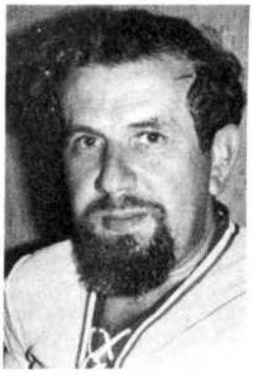
It is thought that total funding for military R & D will increase from $12.6 billion in the current financial year to over $13.5 billion. Within this figure, about $3 billion will be allocated to basic research, an increase of 15% over this year, and 7% above the inflation rate.

One administration official is quoted in *Business Week* as saying that "one of the very few certainties about the new budget right now is that basic research and exploratory development money will be downright abundant."

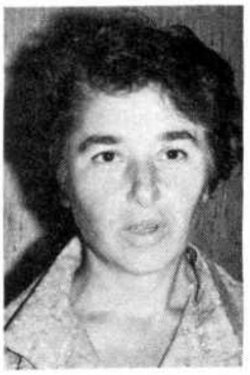
As far as biomedical research is concerned, the Office of Management and Budget is reported to have recommended that the budget of the National Institutes of Health be reduced from its current level of $3.25 billion to $3.03 billion. NIH had asked for $3.22 billion.

Memorial to Birmingham smallpox professor: Birmingham University is to set up a memorial fund to the late Professor Henry Bedson, who committed suicide earlier this year after Janet Parker, a medical photographer, died of smallpox virus which probably came from Bedson's laboratory. Professor Owen Lyndon Wade, Dean of the Faculty of Medicine and Dentistry at Birmingham, proposed the fund, and he hopes that it will provide money for junior staff at the university to travel abroad and undertake research, especially in virology.

In a statement, Professor Wade says that the scholarships would reflect Henry Bedson's care for the underprivileged in the third world. "Henry Bedson was a deeply conscientious man, constantly aware of the humane aspects of his work. His service to the World Health Organisation in the smallpox eradication campaign was outstanding, both in the laboratory and in remote areas of Pakistan and Afghanistan," he said. All who wish to give support to the fund are asked to send their contributions to the Dean's office at Birmingham University Medical School.



'Refusnik' refused: Viktor Brailovskii (right), who in 1977 succeeded Mark Azbel' as organiser of the Sunday seminar for Jewish refusnik scientists, has now been told by the tax authorities that he can no longer give private lessons in mathematics—his sole source of income since he was dismissed from a senior post as a computer scientist in 1972. The tax department said that Brailovskii could not give such lessons without a teacher's licence. No licence was issued, and Brailovskii could therefore at any time face a prison sentence for "parasitism"—i.e., being without visible approved means of support.



Meanwhile, his mathematician wife Irina (right), has received complete security clearance from the Rector of Moscow University, Anatolii Luganov. However, although the chief emigration office of the USSR has accepted the fact of her clearance, she was informed that this made no difference and she would still not be permitted to emigrate.

West Germany to build fast breeder reactor: Chancellor Helmut Schmidt's plan to build a fast breeder nuclear reactor at Kalkar, near the Dutch border, has been approved by the Bundestag, West Germany's lower House of Parliament. The plan was approved in a close vote of 230 to 225, but only after six members of the Free Democratic Party, which is in a coalition with the Social Democrats, finally agreed to abstain, after threatening to vote against the project.

The vote was crucial to Chancellor Schmidt because he believes that nuclear power is vital to West Germany's economic future. However, he faces strong opposition among the members of his Social Democratic Party, especially since last year when the Party chose coal as the chief source of energy in the future and called for a six-year moratorium on building nuclear plants.

Upjohn scientists induce bacteria to produce chick albumin: Scientists at the Upjohn Co., the US-based pharmaceutical manufacturer, claim to have used recombinant DNA techniques to induce bacteria to produce chicken albumin, a protein considerably larger and more complex than previous molecules produced in the same way.

Reporting their results in the Proceedings of the *National Academy of Sciences*, the scientists say that by transplanting a particular gene into bacteria, about 1.5 per cent of the bacteria's protein production becomes chicken albumin, and they expect that this level can be increased to 10 per cent.

According to the company, the experiment lays the groundwork for producing medically-useful quantities of enzymes and hormones, such as the use of bacteria to make the human blood-clotting factor missing from the blood of haemophiliacs.

A refuge for scientists' writings

Professor Margaret Gowing, Honorary Director of the Contemporary Scientific Archives Centre, Oxford, explains how the centre was set up and outlines its work

History is essential to society and science and technology are crucial ingredients of history. History depends on records and therefore scientific and technological records should be systematically preserved. Until recently however records of 20th century scientists and engineers attracted much less interest than those of, say, politicians or novelists.

Most scientists and engineers work in institutions—government establishments, industrial firms or universities—and if all these institutions systematically gathered and retained records the residual problem would be small. But many of them do not. Thus, few British universities have archives staff and fewer still gather the papers of academics as they retire or die.

For these reasons, the Royal Society established a Committee on Scientific and Technological Records in 1967, under the chairmanship first of Sir Harold Hartley and then of Professor Nicholas Kurti. In 1969 a conference called by the committee agreed that scientists' and engineers' papers required special action, partly because general archives tended to be frightened by them. It was further agreed to establish not a special archive but a centre which would locate, sort and catalogue the papers of individual eminent scientists and engineers. Each collection would then be permanently deposited in an appropriate existing library and only the catalogues, reproduced by the Royal Commission on Historical Manuscripts, would be kept centrally and in the copyright libraries. The Wolfson Foundation gave a grant for an experimental period and I was asked to establish a centre at Oxford, where I had just been appointed Professor of the History of Science.

The Contemporary Scientific Archives Centre started in one basement room in April 1973 and has had a total paid staff of two people who do everything from typing, stamp-licking and driving to collect papers, to producing scholarly catalogues and orderly boxed collections, often from extensive and chaotic manuscripts. By the end of August 1978 60 collections had been handed over to 29 different libraries and a further 14 collections were in hand. In addition 175 enquiries had been made. The list at the end shows the variety of disciplines covered.

The collections cover scientists (including medical scientists) and engineers who died after the Second World War. The danger point for dispersal of papers is usually retirement but because of shortage of resources the centre can only deal with a very few collections of people as they retire. The Royal Society Committee decides who shall be included but the list is not confined to Fellows of the Royal Society nor do all Fellows automatically qualify.

By 'papers' the centre does not mean only scientific publications. The word includes papers of all kinds such as notebooks, notes of lectures heard or delivered, papers and correspondence covering all stages and all aspects of a scientist's life from school reports to political activity. The collections vary greatly in size and context. Some scientists keep few papers and some papers regrettably disappear: for example, the contents of the filing cabinets of Nobel prizewinner Cecil Powell, the physicist, were shredded soon after his death. By contrast some collections are very large, cover many years and are of outstanding interest: for example the papers of physicist Rudolf Peierls (including a life-long correspondence with Neils Bohr and Hans Bethe); Charles Coulson (including, besides papers on chemistry and mathematics, his many concerns such as pacifism, Oxfam and Christianity) or Patrick Blackett, the physicist (including his scientific, wartime, Labour Party and overseas activities). Some collections are beginning to form a 'critical mass' for the history of a discipline—for example in computing science.

The formula for the centre has proved very cost-effective, while Oxford University has helped greatly with administrative services and accommodation. Location in Oxford has also brought unstinting help and advice from many individuals. Nevertheless finance has been a constant anxiety, for the initial grants from the Wolfson Foundation and other funds were pump primers. At present the Royal Society and the British Library share the main cost with a smaller grant from the Council of Engineering Institutions. For two years from 1979 the Wellcome Trust will replace the British Library grant.

The centre has blazed a trail. Neither of the two staff members had any previous archival or scientific training but their work has been outstanding in quality and quantity and has attracted considerable interest abroad, especially in North America. The Wellcome Trust is now itself establishing a project on similar lines for medical practitioners and medical-related scientists. The work is becoming more valuable as more professional groups—such as various sections of physicists, molecular biologists, and computer scientists—become increasingly interested in the recent history of their disciplines and as more historians study not only the purely scientific work but the other public work and private interests of scientists and engineers. ☐

For further information and copies of Progress Reports (April and October annually) please write to Mrs Alton, Deputy Director, CSAC, 10 Keble Road, Oxford.

Environmental research in Northern Finland

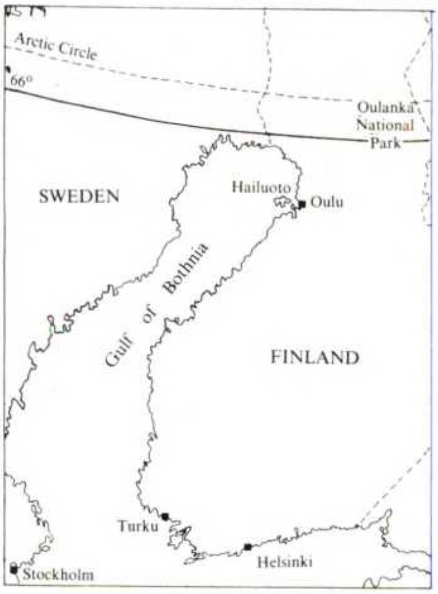
Peter D. Moore, plant scientist at King's College, London, reports from Finland.

JUST 150 km south of the Arctic Circle, Oulu in Finland is one of the most northerly university cities in the world. It lies on the Bothnian Bay, the northernmost spur of the Baltic Sea, and it has provided a centre for a variety of environmental research programmes in recent years.

The Bothnian Bay is covered by ice for between 150 to 200 days of the year, often to a depth of 4 m and has a salinity in its epilimnion of less than 0.2%. It is an unusual aquatic system. Oulu is an industrial city with a population of almost 94,000, so sewage and industrial effluent is a matter for concern. Research conducted by the University of Oulu at the Krunnit and Perämeri Research Stations on islands in the Bothnian Bay, have revealed that levels of inorganic nitrogen and phosphorus in the waters around Oulu are twice as high ($200–250\ \mu g\ l^{-1}$) as those 40 km north. The annual primary productivity is about $32\ g m^{-2}$ in the eutrophicated waters; this is twice as great as that found in the purer waters, but it is nevertheless only about a third of that found in the southern Baltic.

The low annual productivity can in part be accounted for by the prolonged frozen period, but even when liquid, the discolouring effect of humus colloids in the waters of the Bothnian Bay result in poor light penetration. The maximum depth for 1% penetration of light in summer is only 8–9 m.

The islands in the Bothnian Bay are rich in plant and animal life. On the island of Hailuoto the elk reaches its highest population density in Finland, about one elk per square km. Lichens and macro-fungi on the island have been extensively exploited. Of the lichens, *Cladonia alpestris* is valuable in horticulture and since it forms dense carpets beneath the pine forests which cover the dunes of Hailuoto, harvesting by hand is relatively simple. Up to 20% of the cover is removed. It is then left for five years to regrow, the growth rate being about $4–6\ mm\ yr^{-1}$. About 800 metric tons are harvested in Finland annually. The island of Hailuoto is also one of the richest sources of fungi in northern Finland. Estimates place the annual fresh weight yield at $200\ kg\ ha^{-1}$. Yields further north and east in Finland fall off to around $50–60\ kg\ ha^{-1}$, but in the south west they can reach as high as $260\ kg\ ha^{-1}$.



Oulu University has a field station on the west coast of Hailuoto from which survey work is conducted and it has a second research station in the east of Finland in the Oulanka National Park, just outside the Arctic Circle. Here the dense spruce forests with thick layers of moss were used as a site for intensive study in the International Biological Programme by Dr Paavo Havas.

The area is of particular interest to botanists because of the presence of calcium containing metamorphic rocks which permit the development of calcicolous plants such as *Cypripedium calceolarum* and *Kobresia simpliciuscula*. It may be the abundance of cations in local mires which has led to the survival in one inland spot of a population of *Triglochin maritima*, which is normally a coastal species. The existence of such a maritime plant in the Oulanka park led plant geographers at Oulu to speculate about the existence of a sea link between the Baltic and the White Sea when the area was depressed by glacial ice. Dr A. Vasari has been able to trace macroscopic subfossil remains of *Triglochin maritima* in the peats of its current locality going back 8,000 years. On the other hand, there are a number of maritime species, for example *Armeria maritima* and *Plantago maritima*, which have inland (often montane) ecotypes which were widespread during the closing stages of glaciation. *Triglochin maritima* could be another species of that type.

Finnish Lapland can boast yet another research station, this time belonging to the University of Turku, at Kevo in the far north of the country. It lies some 60 km north of the continuous pine forest in sub-arctic birch woods and fjell tundra. In this area, approaching 70°N, permanent ice cores are found within mounds, termed palsas, which typify the peatland habitats.

Much speculation has surrounded these palsa mires, in particular the circumstances under which they were created. Some people, such as M. Salmi (Turku) believe that all palsas began their formation at specific times in the past. He claims that the Lapland palsas fall into two groups which were initiated about 5,000 and 3,000 years ago respectively. Palsa studies in Ontario, Canada, by J. B. Railton and J. H. Sparling (Toronto), however, indicate a continuous and non-phased cycle of palsa initiation, growth and erosion.

M. Seppälä, working at the Kevo Subarctic Research Institute has introduced a novel, experimental technique into the discussion. His observations led him to believe that palsa mounds

Left : a patch of Cladonia alpestris; *right : growing palsa hummock*

0028–0836/79/0277—0008$01.00

are created as a result of a failure of snow to accumulate on certain parts of the bog surface, so allowing ice penetration of those parts to be deeper. In winter, the wind blows the snow unevenly over the mire and, when temperatures fall to less than −40 °C, frost may penetrate to depths of 1 m.

If this explanation is correct, then it should be possible to create palsas experimentally by regular snow removal. Seppälä has contrived such an experiment and has kept experimental plots clear of snow during the past two winters. In the first winter, frost penetrated to 85 cm in the cleared area and only to 45 cm in the control. By mid August the control was ice free but the experimental plot was still frozen to a depth of 45 cm. In the second winter the artificial palsa had an ice core 100 cm deep and ice was still surviving to about 60 cm this September. The expansion of the ice core has now led to the surface of the mire in the cleared area being elevated 20 cm above its surroundings. This in turn has resulted in a natural wind clearance of the winter snow leading to more rapid palsa growth.

Studies such as these, together with lichen productivity, reindeer ecology and arctic nutrient cycling processes, all being carried out in Lapland's research stations, will undoubtedly contribute much to our lamentably poor understanding of the ecosystems of the far north. ☐

Down in a Polish forest, something is stirring . . .

SOUTHERN Poland, from an ecologist's point of view, could well be a nightmare—a jumble of conurbations, industrial enterprises and national parks, stretching in a wide belt across the country, while the high Sudeten-Carpathian mountain barrier effectively inhibits north-south ventilation. Not surprisingly, the forests of the area have deteriorated, and research into their management has been ranked as a "key" project.

In 1976, a detailed survey was begun into the management of these forests, with the participation of thirteen research institutions—four from the Polish Academy of Sciences, seven from the Jagellonian University and other academic institutions in Krakow, and two non-academic institutions (the Institute of Meteorology and Water Management and the Institute of Environmental Protection.) Some 70 senior research workers are involved in the project, ranging from ecologists and dendrologists to geochemists and economists.

The area chosen for study was the Niepolomice forest, some 30 km east of Krakow. The forest consists of two sections, a northern, deciduous part (~ 3,000 ha) and a southern coniferous part (~ 8,000 ha) mostly pine. Conifers are the most susceptible to pollution.

The forest, formerly a royal hunting park, is of considerable historical and touristic significance. It is ecologically unfortunate, therefore, that in the late 1940s, the new industrial town of Nowa Huta, with a steel mill still the largest in Poland, was established between Krakow and the Niepolomice forest. The prevailing wind is from the west, so that the forest receives the major proportion of industrial emission from Nowa Huta.

The siting of Nowa Huta was apparently primarily a politico-demographic decision, at a time when large-scale enterprises were seen to be the answer to the problem of rebuilding a war-shattered economy, at a time when no government anywhere was more than dimly aware of the concept of ecology as a planning factor.

After 25 years, however, the Niepolomice Forest was unhealthy, and a five-year project was undertaken, not only to find a remedy for Niepolomice, but also to establish a detailed mathematical model of the forest eco-system, and to propose methods of forest management in urban environments which could be extended to similar systems elsewhere.

On the basis of this computer model, a number of parameters were selected for field study, including dust-fall, wet and dry deposition of sulphur, heavy metal contamination, acidification of tree bark, loss of photosynthetic efficiency of pine-needles, energy flow via small consumers and predators, and the quality of roe-deer antlers. The situation was found to be far from promising: dust fall 45—80 tonnes/km^2-yr, wet and dry sulphur deposition 3·6—6·4 tonnes/km^2-yr, potential photosynthetic activity of pine-needles decreased by 13—18%. The total energy flow diagram revealed a slowing down of decomposition, producing a "carpet effect" under the trees, since the pine litter takes up to 10 years to break down completely, instead of the usual two, apparently due to inhibition of microbial activity, posibly due to heavy metal pollution.

Recent introduction of electrostatic precipitators in the Nowa Huta factories is improving the dust situation to a certain extent, but the problem of wet and dry sulphur deposition remains, so far, virtually insoluble. One proposal made by the research team is aerial spraying of the forest with lime, neutralising the sulphorous and sulphuric acid. This is being introduced into the nutrient spraying programme which has been carried out over the last three years and which is already proving a palliative—the timber increment has increased somewhat and the overall condition of the pines is improving. (Unfortunately, there is also the side effect of increased weed-growth and the eutrophication of the small river Drivnka).

In addition to this spraying, the team have put forward several other draft proposals. The forest stands, they say, should be rebuilt into a mixed forest with the possible introduction of exotic species such as black pine and Japanese larch at the western edge. (It is hoped in the course of the next ten years to determine the most resistant strains). The water-table should be raised by regulating the drainage channels in order to provide more available nutrients for the roots. Wild-life management (roe deer, red deer, wild boar), should be optimised, and steps should be taken to reduce tourist pressure by organising 'nature trails' on the British model.

A number of major problems still, of course, remain. For example, the net sulphur intake of the total biomass is still ~2 kg/year and the well-being of the forest can only finally be ensured by the radical control of industrial emissions. Nevertheless, the valuable contributions of the multidisciplinary team towards containing this problem is already effecting some amelioration, and at the same time has produced a valuable spin-off in the form of a number of published papers, and a book now in production, dealing with basic concepts of forest ecology and management.

Piltdown hoax: new light

SIR,—If L. B. Halstead (2 November, page 11) had taken the trouble to look a little more closely at the evidence presented in the scientific papers on the Piltdown forgery (as well as in my book, *The Piltdown Hoax*) he would surely have realised (and this goes also for Mr Richard L. E. Ford) that the late Professor Douglas' arraignment of Professor Sollas is really without any foundation. The "evidence" of Sollas as instigator and co-conspirator with Charles Dawson amounts to very little and that, quite trivial and unconvincing.

Dr Oakley has already, in his letter to *The Times* (7 November 1978) shown that Douglas was mistaken in thinking that the Mastodon bones he said he gave Sollas were part of the Piltdown assemblage. The receipt by Sollas, according to Douglas' recollection of 68 years ago of a packet of potassium bichromate can hardly be taken as positive evidence for the reasons which Dr Oakley gives in his letter.

Moreover, Douglas should have known that Dawson had admitted to the use of bichromate, that Woodward knew this, and two people told me spontaneously (that is before the disclosure of the hoax) that they were aware of Dawson's staining activities. Moreover, as Oakley and I have shown, Dawson used a number of different methods of staining and we are left to suppose (on no evidence whatever) that Sollas initiated Dawson in all these methods.

The third item furnished by Douglas in his remembrance of Sollas borrowing apes teeth from the Anatomy Department at Oxford. If Douglas had remembered Sollas borrowing an ape's jaw or even better, an orang's jaw, that would have been rather more interesting, because it was an orang jaw with its molars that was used for the plants at the two Piltdown sites. To say that Dawson needed Sollas as a supplier is sheer guess work and unnecessary at that.

A likely source, as I have pointed out, was Abbott of Hastings, not to mention local museums and even straightforward purchase. A fourth item of "evidence" is the Sherbourne horse's head. For Douglas to say that this little curiosity (which cannot in fact be brought home to Sollas) is "an almost similar act" to that of the elaborate Piltdown Forgery is quite fatuous.

The motive attributed to Sollas for the humiliation of Smith-Woodward does not make sense. If his plan was to "expose" Smith-Woodward's gullibility and incompetence, why should he have so firmly supported the new *Eoanthropus dawsoni* in the first place? Why did he not wreak his vengeance by exposing the forgery at any time after Dawson's death in 1916? Halstead argues disingenuously that once Dart had discovered *Australopithecus* Sollas would have known that it was only a matter of time before Piltdown Man was exposed. But if Sollas was so sure about the status of *Australopithecus africanus* in relation to Piltdown, surely Dart's discovery provided the perfect opportunity (from 1925 onwards) to expose both Piltdown and Smith-Woodward.

The truth is that none of the leading palaeontologists of the day, including Dart and Broom (despite their many australopithecine discoveries), nor Leakey, nor Le Gros Clark, could see that Australopithecus made Piltdown Man impossible and (*ergo*) fraudulent. The reasons for this myopia, I have discussed elsewhere. A hint from Sollas or later Douglas, to any one of these would have been sufficient. Halstead is simply arguing from hindsight in suggesting that Sollas went to his grave rubbing his hands in anticipatory glee.

In my book I point out in some detail that a "mastermind" to guide Dawson through all the years of the complicated sequence of the events at Barkham Manor and Sheffield Park would need to be of Mephistophelean calibre. It would be tedious to repeat here all that is implied in asserting, or postulating, a continuous connection between Dawson and Sollas. Douglas and his sponsors do not even begin to face up to this. In the case of Sollas it would be quite as difficult a task as that which faced the recent accuser of Elliott Smith. Messrs. Halstead and Ford might care to look for proof of Sollas' alleged activities in the light of the arguments in my paper on Elliott Smith and Piltdown (*Symp. Zool. Soc. Lond.* no. 33, 23–26; 1973).

One thing the late Professor Douglas has succeeded in doing. He has certainly added a mystery of his own devising to the Piltdown saga—why should Douglas on such incredibly weak evidence take the trouble to besmirch Sollas' reputation?

Yours faithfully,
J. S. WEINER

Pall Mall,
London

Proliferation

SIR,—In your article 'Is Proliferation Unstoppable' (26 October, page 681), you say that after the May 1975 Review Conference of the Treaty on the Non-Proliferation of Nuclear Weapons ". . . no outsider proceeded to sign". You cite this as evidence that "the NPT could hardly be said to be an unqualified success".

The facts are that during and after the conference eleven additional states joined the NPT. The new states included Libya, Venezuela, Japan, Switzerland and Portugal. A growth of 14%, including some important states, is not bad going. The treaty now has 104 members and Indonesia and Turkey are in the process of ratification.

Only 13 non-nuclear weapon states that have any significant nuclear plant remain outside the treaty; they include several of those mentioned in your article. However, in eight of these 13 every nuclear plant of which we are aware is under safeguards pursuant to non-NPT arrangements (like the German/Brazilian agreement). Only five non-nuclear weapon states have unsafeguarded plant—these include India, Israel and South Africa.

We agree that everything should be done to strengthen the non-proliferation regime, but one should not denigrate the considerable success of the treaty. A few years ago, German and Japanese ratification was by no means certain; now almost every leading industrial non-nuclear weapon state is a party. Moreover, IAEA safeguards have become much more effective and stringent in recent years.

Yours faithfully,
HANS-FRIEDRICH MEYER

IAEA, Vienna, Austria.

Responsible statements

SIR,—Though *Nature* is to be applauded for welcoming presentation of alternative views on controversial issues, I would think that the nature of the journal requires the editors to hold authors to a reasonable standard of responsibility, even on issues that evoke ideological conflicts. I therefore wonder why you lend the dignity of your pages to such statements as the following, in an article by Jonathan King (2 November, page 7): "Now we don't have a law in the United States that keeps anybody from introducing any gene into an epidemic strain of *E. coli* or *salmonella* or *Shigella*; and there are forces in that direction because of patents. If somebody else has a patent on making insulin in *E. coli* and you recognise that market what do you do?"

Yours faithfully,
BERNARD D. DAVIS

Harvard Medical School,
Boston, Ma., USA

Helpful oil companies

SIR,—The article on wave energy (30 November, page 433), gives a poor impression of the helpfulness of the oil companies, which I would like to correct.

UK OOA wave data is commercial and confidential, and there was a time when Wavepower Limited could not have access to it. However, that access was cleared some time ago via the Department of Energy—I was misinformed, and misled your reporter.

Nevertheless you misrepresent both the oil companies and myself when you say that I have been unable even to arrange a visit to one of the platforms. My enquiry at the conference was the first time of asking, and I have already had two offers in reply.

Yours faithfully,
M. J. PLATTS

Wavepower Limited,
Southampton, UK.

Spacecraft charging

from Gordon L. Wrenn

Halloween is traditionally the time when things go bump in the night and was somehow appropriate for a Spacecraft Charging Technology Conference sponsored jointly by the United States Air Force and NASA. Justification for the three day gathering of some 150 scientists and engineers really stems, not from physical bumps but from a host of status anomalies seen on operational spacecraft at high altitudes. The proposition is that these malfunctions, ranging from nuisance level to a possible fatality, are caused by electrostatic charging events which occur near local midnight when a satellite passes through the shadow of the Earth. Six sessions at the impressive Air Force Academy in Colorado Springs served up 54 well presented papers; these demonstrated the obvious interest and support that the field has attracted. Why, then did the Conference close with a panel discussion on the theme 'The Spacecraft Charging Hazard—is there a credibility gap?'; futhermore why was the only answer 'Yes'.

The electrostatic potential of any satellite will float to a value which produces zero nett current. At low altitudes, a high concentration of cold ionospheric plasma clamps the floating potential at a small negative value. Up at several Earth radii, outside the plasmasphere, the cold plasma decreases, the photoemission current due to sunlight becomes dominant and the spacecraft charges to a few volts positive. In eclipse negative charging is to be expected but the absence of cold protons could permit a potential build up to very high values—20 kV has been observed. The geosynchronous orbit (at 6.6 R_E) is a popular one for a variety of applications satellites but with eclipse times of up to 75 minutes and a location at which intense fluxes of high energy electrons are encountered during periods of geomagnetic disturbance, it seems to be particularly susceptible to charging. The problem is complicated by the multiplicity of surface materials in use. In the same way that there is little danger when lightning strikes an aircraft, overall charging is not a threat but the possibility of differential charging presents the real hazard; subsequent discharge could generate a large current spike on power or ground lines and affect sensitive solid state devices.

Since the last such conference in October 1976, much good work has been done on modelling both the particle environment and electrostatic fields around spacecraft. Considerable advances have been made in understanding surface material properties and developing active potential control systems utilising electron or ion beam emitters. Studies are now well in hand for huge space platforms such as solar power satellites with areas over 100 km^2, and charging characteristics will clearly be of utmost importance to their design. One outcome of the earlier conference was a resolution to include simple discharge monitors on all operational spacecraft but this has been largely ignored and the study of anomalies has progressed little. Satellite designers have not been convinced that the hazard is serious enough to justify increased production costs.

The scepticism is bred by a number of missing links in the whole discussion. A considerable catalogue of anomalies does have some correlation with geomagnetic activity but generally does not show an expected pattern with local time. Evidence for kilovolt charging comes exclusively from the ATS 5 and ATS 6 satellites but even these exhibited no corresponding status anomalies. There have been many other suitably instrumented satellites for which charging events have remained absent or undetected. Laboratory simulation of the charging process is difficult and has not yet been achieved on a system level. NASA and USAF hope to obtain all the answers with the SCATHA satellite which is due to be launched in January 1979; it promises a concerted attack on all the factors which make up the charging equation. Whilst it necessarily represents a compromise between the desire to create charging problems for study and the need to pursue techniques which might overcome these same problems, it should mark a big step forward on the trail of missing links.

ESA, the European Space Agency, is in a strong position to contribute to the subject. In addition to having a good background in the physics of space materials, it has, in orbit, OTS and METEOSAT spacecraft with the opportunity for careful monitoring of anomalies and it has GEOS 2. In contrast to ATS, the electromagnetic cleanliness of GEOS is excellent. Over 96% of the surface has been made conducting by the use of special paints and an indium oxide coating for the solar array. Differential charging has been avoided but satisfactory thermal characteristics have been achieved and for the first time reliable cold plasma measurements are available at 6.6 R_E. So far no significant charging events (in excess of about 150 V) have been seen on GEOS and it may be that its overall susceptibility is very different from that of ATS. If this is true, it is probably due to different secondary emission properties of the resulting retarded impact energy, the secondary electron yield exceeds one. Selection of suitable secondary emitting surfaces could provide an inexpensive method of limiting the extent of charging.

It is planned that GEOS and SCATHA experimenters should collaborate closely on data interpretation and this presents the best chance of closing any credibility gaps. As to the real significance of the whole issue, it

could be that the approaching solar maximum will provide the opportunity for everyone to judge; our lives are now much more dependent upon synchronous satellites than they were 11 years ago. ☐

Membranes and parasites

from D. F. H. Wallach

A WORKSHOP on the membrane pathobiology of tropical diseases held recently* brought together experts in the various diseases and membrane biologists, biophysicists, biochemists and immunologists to discuss ideas and techniques concerning membrane structure and physiology in relation to problems of parasite/host interactions.

It became evident very early in the meeting that membrane biology represents a major area of common ground for all the major parasitic diseases. Membrane studies are relevant to the modes of action of antiparasitic drugs, and membrane-bound antigens may be of particular importance in the development of serodiagnosis and immunoprophylaxis.

Intracellular parasites, such as the plasmodia which cause malaria, interact with the host cell membrane during entry and exit from the cell, and may modify the membrane during their intracellular development. These different processes may be subject to interference by immunological or chemotherapeutic methods. At least three organisms of those under consideration, *Mycobacterium leprae, Leishmania* and S. American trypanosomes, are taken up primarily by macrophages by phagocytosis, but have evolved mechanisms by which they evade the normal destruction of foreign material within phagolysosomes. These organisms may also avoid immunological defence mechanisms through their sequestered intracellular location.

The presentations on extracellular parasites revealed additional mechanisms which help them to evade host immune defences. African trypanosomes have the capacity for extensive variation of the chemical structure and antigenic characteristics of a glycoprotein surface coat lying outside the plasma membrane, and invading schistosomes have the remarkable ability to incorporate into their surface membranes a variety of host plasma membrane components, including blood group substances and components of major histocompatibility antigens, mimicking host surface membrane antigenicity, and to shed, at least *in vitro*, surface membrane material in a manner reminiscent of the behaviour of some tumour cells.

The workshop revealed that, although extensive immunological information exists on changes in the plasma membranes of host cells and the surface coats or membranes of pathogens during the processes of infection, evidence on the biochemical, biophysical, physiological, genetical and micromorphological processes involved is meagre or totally absent. However, recent developments now permit these approaches to studies of parasite infection. For example a major causative agent of human malaria, *Pl. falciparum*, can now be cultivated continuously *in vitro*, the technique has been established in several laboratories around the world and its expansion to mass-cultivation seems feasible. The major steps in the fractionation of host cell (erythrocyte) and parasite antigens in a model monkey malaria have been achieved; parasite modification of host cell membranes can be analysed both biochemically and immunochemically and the system allows rigorous biochemical analysis of parasite, parasite-induced and host-cell-modified membrane lipids and proteins, as well as numerous other metabolic variables. Although it has not yet been possible to cultivate *M. leprae in vitro*, the organism has been found to grow well in the liver and spleen of most forms of nine-banded armadillos. This permits production of large amounts of organisms free from host cell material, and studies are in progress which should eventually lead to vaccination and improved chemotherapy. Studies of the amastigote forms of leishmania growing within macrophages have revealed that some forms of leishmania modify the surface of host cells in a fashion which is recognisable immunologically. Some forms of trypanosomes can be cultivated either in the absence of cells, or using host cells only as 'feeder' cells. Some forms of S. American trypanosomes can now be cultivated on a scale adequate to permit isolation of mutants, setting the stage for genetic experimentation. Moreover, fractionation and biochemical studies, involving both surface and cytoplasmic membranes, have been initiated using these organisms, as well as leishmania.

Animal models exist for schistosomiasis and, although some 'conventional' biochemical/molecular biological approaches appear less readily applicable to this area, the discussions pointed to the existence of an important group of microtechniques, including micropuncture, microcatheterisation and X-ray microanalysis, which are immediately available to the resolution of critical areas in schistosomiasis. Many of these approaches appear equally relevant to filariasis.

The workshop showed that, in spite of promising beginnings in basic research on the six major diseases, there are important lacunae in information about both parasite and host-cell membranes, which might be filled by application of techniques for membrane studies which are now standard in many laboratories. Present knowledge on the relationships of intracellular parasites within the host cell raise many pertinent questions regarding transport mechanisms within the parasite/host cell complex, particularly of K^+, Na^+ and Ca^{2+} transport and the ionic preferences of intracellular compartments. These issues could be resolved by flux analyses, possibly combined with specific ionophores, and also by use of intracellular ion-localisation techniques. The effects of possible parasite-induced alterations of Ca^{2+}-fluxes deserve major attention. In another vein, the major anion-transport protein of erythrocyte membranes has been extensively studied, many of its active sites can be specifically labelled and application of these approaches to the membranes of erythrocytes parasitised by malarial parasites is practicable. Such labelling methods could also fruitfully be extended to macrophages (normal and infected) and to schistosomes.

Most participants felt that further progress in the understanding of the six diseases required basic research in the following areas.

Host and parasite surface receptors; parasite surface coats; passage of intracellular parasites into and out of cells fractionation of host-cell and parasite membranes; membrane composition of host cell and parasite; antigenic variation in parasite and parasite-induced antigens, and immune mechanisms; application of the hybridoma technique to the study of parasite antigens; transport and permeability; membrane enzymes; genetics; propagation of the pathogenic organisms involved; model systems.

Virus precursor shedding from mammary tumour cells

from A. J. McClelland

IN 1976 Ritzi *et al.* made the intriguing observation that mice with murine mammary tumour virus-induced mammary tumours had much greater amounts of the major mammary tumour virus (MuMTV) structural glycoprotein gp52 in their blood than did mice with no mammary tumours. This was true even when the tumour-free mice were productively infected with MuMTV and had very high levels of gp52 in their milk. Ritzi's work raised several interesting questions. How are the MuMTV glycoproteins synthesised and assembled, what is the mechanism and biological function of gp52 secretion by mammary tumour cells and are there differences in the synthesis and assembly of MuMTV in normal and transformed cells?

Thanks to the establishment of continuous MuMTV-producing mammary tumour cell lines (Ringold *et al. Virology* **65,** 135; 1975; Sarkar *et al. Virology* **77,** 12; 1977) some answers to the first question at least have been found. It appears that the MuMTV glycoproteins are derived from a single precursor molecule, designated pre-gp70 (molecular weight 70,000) which is then cleaved to form the glycoproteins used in virus assembly (Racevskis & Sarkar *J. Virol.* **25,** 374; 1978; Schochetman *et al. Virology* **85,** 168; 1978; Dickson & Atterwill *J. Virol.* **26,** 660; 1978). Even more interesting is the unexpected discovery that the MuMTV glycoprotein precursor is shed from the surface membrane of the tumour cells in which it is synthesised.

Racevskis and Sarkar's discovery, that both gp52 and its precursor, pre-gp70, were present in virus-free culture medium from MuMTV-producing cells was unexpected because it was the first time that a glycoprotein precursor had been found in cell culture medium and because cell surface labelling studies had shown that, unlike MuMTV gp52, pre-gp70 is not present on the surface of MuMTV-producing cells.

Since pre-gp70 is shed into the medium of MuMTV-producing tissue culture cells, yet is apparently not available for surface labelling, two populations of pre-gp70 may exist. One population, destined to provide mature proteins for MuMTV assembly, may be cleaved before reaching the cell surface to produce gp52. The gp52 is then inserted into the cell membrane and leaves the cell only when it is incorporated into a virus particle. The second population of pre-gp70 molecules are shed from the cell without ever becoming integrated into its surface membrane. In that context, it is interesting to note that pre-gp70 has not been reported to be packaged within mature MuMTV particles.

The anti-gp52 serum that Ritzi used (*Proc. natn. Acad. Sci. U.S.A.* **73,** 4190; 1976) reacts with both gp52 and pre-gp70 and thus the glycoprotein that was detected in the plasma of tumour-bearing mice might have consisted of gp52 alone, gp52 and pre-gp70 or even pre-gp70 alone. The discovery that pre-gp70 is shed from mammary tumour cells in tissue culture could therefore explain the observation of Ritzi *et al.* but the mechanism by which MuMTV glycoproteins are shed from cells and the biological significance of shedding are still unknown. However, one can reasonably speculate that shedding helps MuMTV-producing tumour cells to escape from the immunological defences of the host. Immunisation studies have shown that gp52 is the most potent immunogen for protecting mice from exogenous MuMTV infection and subsequent tumorigenesis (Sarkar & Moore *Cancer Res.* **38,** 1468; 1978). It is therefore possible that the release of large quantities of gp52, and possibly pre-gp70, into the plasma provides a means of complexing (and thus, in effect, neutralising) cytotoxic antibodies against the glycoprotein, thereby increasing the survival advantage of MuMTV-producing tumour cells.

Whatever the biological function of glycoprotein shedding, it provides a unique opportunity to investigate two apparently different pathways of pre-gp70 transport and/or processing. It is still not known if MuMTV-producing normal mammary gland cells cultured *in vitro* would shed viral glycoproteins. If it is found that such normal cells do not exhibit the shedding phenomenon, membrane changes taking place in the transition from normal to tumour cells might be studied using MuMTV glycoprotein shedding as a marker for cell transformation. □

A. J. McClelland is an Associate in the Laboratory of Veterinary Oncology, Memorial Sloan-Kettering Cancer Center, New York.

Versatile accelerators

from R. G. P. Voss

THE range of uses to which small accelerators are now put is astonishing. These were covered exhaustively in a recent conference in Texas on the application of small accelerators*. The word 'small' is perhaps misleading: there were progress reports on the two very large tandems being built in the United Kingdom and in the United States, at Daresbury and Oak Ridge respectively, and experiments carried out on the 800 MeV proton linear accelerator at LAMPF and the 20 GeV electron linear accelerator at SLAC were reported. Perhaps, as someone remarked, even small accelerators are big in Texas.

Amongst the many different fields, one topic inevitably attracted considerable interest: the application of accelerators to medical purposes. Several papers dealt with the production of radioisotopes by cyclotrons, tandems, and linear accelerators. Information was given on targets, yields, the subsequent radiochemistry, the various uses of the isotopes, and instrumentation to detect localised radioactivity in the human body. Considerable work has been done in recent years at Los Alamos with pions produced by the proton linear accelerator. This is a huge machine, 850 m long, and its suitability for widespread use in medical work is obviously restricted. As a consequence a smaller accelerator, a mere 120 m long, is now being developed. It is known as PIGMI (Pion Generator for Medical Irradiations) and is now in its third year of development, with emphasis on being less expensive ($10M) and more reliable than accelerators for pure research.

A related field of great interest is that of computed tomography, and developments following from the original EMI CT scanner were presented. Work on proton CT at Los Alamos was described by W. F. Hanson (Oak Ridge Associated Universities) and R. R. Highfill and M. E. Phelps (University of California at Los Angeles) gave a paper on positron tomography. By detecting the annihilation radiation from positrons one can make an *in vivo* study of physiological processes in specific regions of the body. The need for positron-emitting radioisotopes (such as ^{11}C, ^{13}N, ^{15}O, ^{18}F) with short half-lives means that

---

*5th Conference on the application of small accelerators, North Texas State University, Denton, Texas, 6–8 November 1978. Abstracts are published in the Bulletin of the American Physical Society, volume 23, number 8, 1978.

0028–0836/79/0277—0013$01.00

accelerators must be available very close to the medical centres.

Two papers dealt with a subject of great topical interest. K. H. Purser (General Ionex Corporation) reviewed the use of electrostatic accelerators to give ultrasensitive particle identification, resulting in a spectrometer which is sensitive to a few tens of particles in a background of 10^{18}. By stripping electrons after an initial acceleration, one dissociates molecules and so enormously simplifies the identification of the atoms one is looking for. These need not be radioactive isotopes (as was necessary, for instance, in the previous method of counting ^{14}C decays): it is now possible for instance to study Li, Mg, Si and Cl. Moreover, the rare earths form excellent tracers. Extensions to the technique are leading to a new generation of secondary ion mass spectrometers many orders of magnitude more sensitive than earlier ones. H. E. Gove (University of Rochester) reviewed progress in ^{14}C dating in the remarkable 18 months since the technique of using an electrostatic accelerator was first reported. It is possible to date back to 70,000 years or even earlier, and a few milligrams of sample are sufficient (Doucas *et al.* *Nature* **276,** 253; 1978 and Hedges & Moore *Nature* **276,** 255; 1978). The technique is being constantly extended. Work has been done on ^{36}Cl for instance, for dating old ground water with a view to the safe storage of nuclear waste (as reported in this issue of *Nature* on page 22) and on ^{10}Be for 'million year geochronology'.

A number of papers dealt with various aspects of thermonuclear reactions. D. J. Nagel (US Naval Research Laboratory) discussed the progression from laser light through electrons to light ions and then to heavy ions in developments aimed at thermonuclear fusion. Currents of 300 kA of protons of energy about 1 MeV can be produced, with substantial fractions of a terawatt in a few nanoseconds. Even higher pulse energies are planned using 25 GeV uranium ions. Intense ion beams on solid targets will produce and heat plasmas to temperatures of the order of 10^5 K. He also described fascinating work on multi-atom projectiles: diamond dust is levitated while charge is built up with, for instance, a proton beam. Then the dust particle is accelerated by a 2 MV Van de Graaff accelerator. Twenty such particles can be accelerated per day! These are then fired into solid targets, to get plasmas with temperatures of the order of 10^4 K.

Work on new uses of polarised beams was presented by S. S. Hanna (Stanford University). A polarised beam is implanted in a target, and if this has the appropriate properties the polarisation transferred to the nuclei of the target can be preserved. This serves as a probe for studying magnetic moments, quadrupole moments (if an electric field is present), hyperfine fields, lattice effects, and for solid state problems such as the relaxation time of an implanted nucleus in a holding material. Polarised beams are being used as gas targets, thus enabling polarised-polarised reactions to be studied.

S. Raman (Oak Ridge National Laboratory) reported on a search for superheavy elements in giant-halo monazite inclusions. Use was made of the particular advantages of synchrotron radiation (from the electron storage ring SPEAR at Stanford) to induce fluorescence X rays. No sign of superheavies was detected.

Many other topics were covered: geoscience and mineral exploration, neutron activation (with applications to agriculture, archaeology, the life sciences), trace element analysis, radiation processing of foods and sterilisation of medical products, the curing of paint, the crosslinking of polymer insulating and packaging material. Papers on ion implantation covered amongst other things the processing of semiconductors, integrated circuits, metal corrosion, and a project for an implantation for silicon solar cell processing (P. H. Rose, Nova Associates) with a capacity of about one acre per day!

The overall impression of the conference was the enormous and rapidly growing use of accelerators in an extraordinary range of applications. ☐

Semliki forest virus: key to the MHC?

from Polly Matzinger

IMMUNOLOGISTS have long been intrigued and biochemists frustrated by the cluster of genes collectively known as the major histocompatibility complex (MHC). To immunologists it is a fascinating bit of chromosome. Cell surface molecules coded by genes in the MHC have a central role in the processes by which the immune system recognises self from non-self (see *News and Views* **272,** 112; **274,** 840; 1978;). They are involved in the recognition processes which lead to graft rejection, immunity against infectious agents, susceptibility to a wide range of diseases, and have even been shown to affect mating preferences in mice (*Immunogenetics* **6,** 265; 1978). Consequently, many theories and much of the current work in immunology concern the MHC.

The MHC has been difficult to study biochemically. Purification and characterisation of its products has been an arduous task replete with surprises. In 1956 the mouse MHC, H-2, was thought to be DNA. In 1957 it was a carbohydrate and by 1966 it had turned into a lipid. Today it is a glycoprotein with the arguments still raging over the antigenic importance of the carbohydrate parts (Parish *Immunogenetics* **6,** 343; 1978). A major cause of frustration and confusion has been the difficulty of purifying MHC products in sufficiently large quantities; however, a recent article from Helenius *et al.* (*Proc. natn. Acad. Sci. U.S.A.* **75,** 3846; 1978) promises an easier road ahead.

Ari Helenius and his colleagues report that Semliki Forest Virus binds preferentially to MHC products on the cell surface. They discovered this while testing binding properties of the virus. They were using antibodies directed against Semliki Forest Virus to detect its binding to cells and antibodies directed against H-2 as a control. To their surprise they found that target cells which had been incubated with Semliki Forest Virus would no longer bind anti-H-2 antibodies. They postulated that the virus was binding to H-2 and therefore blocking the H-2 molecules from the anti-H-2 antibodies. Further tests showed that Semliki Forest Virus also bound to human cells bearing HLA molecules (the human MHC) but not to their mutant counterparts lacking HLA. Moreover, the virus binds to artificial lipid vesicles which have had MHC products inserted and can even be used on a Sepharose column to purify MHC molecules from solubilised membranes. So Semliki Forest Virus should make the purification of MHC molecules much simpler.

Like protein A from *Staphylococcus*, which is useful in the purification of antibody molecules, Semliki Forest Virus has another interesting use. Protein A, which binds to the Fc part of antibodies has been used in phylogenetic screens to study the evolution of antibodies (Kronval *et al. J. Immun.* **104,** 140; 1970). Semliki Forest Virus may do the same for the MHC. There

has been much speculation about the evolution of the MHC. Simple self–non-self discrimination is found in very primitive organisms. Sponges only fuse with genetically similar sponges and, in colonial ascidians, recognition of the products of a single locus determines whether free swimming tadpoles will join up to form colonies. Even mating preference is controlled by this locus in ascidians. It has been postulated that the MHC may have evolved from genes that control such primitive self recognition and that our immunological recognition system is simply a more sophisticated version of that of amoebae and sponges (Langman *Rev. Physiol. Biochem Pharm.* **81**, 1; 1978; Lafferty & Woolnough, *Immun. Rev.* **35**, 231; 1977; Burnett & Fenner *The Production of Antibodies*, Cambridge University Press, 1949). So far such speculation has chiefly fuelled fireside debates, but now Semliki Forest Virus could be used to test these theories.

The virus has an amazingly wide host range, having been grown in insect as well as avian and mammalian cells. To infect such a wide array of cells it must either have a wide range of cell surface receptors or a receptor which is evolutionarily highly conserved. A hint that the receptor is conserved comes from Helenius *et al.*'s paper showing that the virus binds both human and mouse MHC molecules. Will it bind to primitive organisms? We may soon have an answer from Virginia Scofield and Irv Weissman at Stanford who are testing its binding to the colonial ascidian *Botryllus schlosseri.* Binding *per se* is no proof that the molecules are evolutionarily related, but Lee Hood's group at CalTech may have a solution to that problem. They will soon be able to sequence picomolar quantities of protein at the rate of 40–60 residues a day. It will then be entirely possible to isolate a Semliki Forest Virus binding protein from a small number of *Botryllus* (say one seaweed leaf's worth) and sequence it to see how it compares with the evolutionarily more advanced MHC molecules.

The story is told of an explorer who, coming on a forest not marked on his maps of Africa, asked his native guides what it was called. 'Semliki', they said, shaking their heads, 'Semliki'. Little did he know when he named it Semliki that Semliki means 'I don't know'. Ironically the virus named Semliki may well fill in some of the gaps in our knowledge of the elusive MHC. ☐

Storing energy as acid

from A. B. Hart

WHEN everybody had a woodpile, a coalshed or an oiltank there was little fuss about matching the rate of production of an energy source to the consumer's need. But for the consumer with a taste for the convenience and cleanness of electricity in his domestic or industrial premises it is another matter. Although electricity plants can lay in stocks of coal, oil or uranium the plants themselves are costly and complex and it is both financially and mechanically unsound to turn them down as the demand for electricity falls back in its diurnal or seasonal cycle. Indirect storage of domestic electricity is possible in off-peak space heating and in the future perhaps in electric battery motor cars. This kind of consumer 'storage' may well play a large part in the future planning of a power network, but there will remain a need for a balancing store near the generators and under the control of the operators of the network, so that the plant can be kept running at a steady load.

In recent years true storage has been available using hydroelectric plant in reverse; storing electrical energy as potential energy of water. But hydroelectric plants are usually expensive to build and in the UK there are going to be few sites left to meet the demand for storing night-time electricity expected around the turn of the century. This is when the proportion of electricity generated by nuclear power (not to mention wind and wave power with their unavoidably intermittent characteristics, which call for a very large storage element) is likely to be increasing rapidly.

Other methods of energy storage have recently attracted much interest. Flywheels, superconducting magnets, compressed air and heat, underground water reservoirs, and rechargeable electrochemical batteries are all under scrutiny (Gardner *et. al. CEGB Research* **2**, 1975). One of the more radical ideas is to make hydrogen from spare electricity by electrolysing water or directly from nuclear heat. The hydrogen need not be entirely reconverted to electricity; it can be used as a chemical feedstock—for fertilisers, petrochemicals and for hydrogenating coal to provide liquid fuels. This is an introduction to the much broader idea of the 'hydrogen economy' (Getoff *Wasserstoff als Energieträger*, Springer Verlag, Vienna 1978) a scenario in which all primary energy sources old and new, fossil, nuclear, solar, winds, waves and biomass, are converted into hydrogen which is stored as liquid or gas and piped to the consumer for his total energy neds. Objective attempts to make an economic case for such an all-embracing hydrogen energy system depend very much on the cost, efficiency and safety of storing the hydrogen. For fuelling transport one could use liquid hydrogen or a metallic hydride, neither of them cheap nor particularly attractive, the former because of the cost of the container, the latter because of the heavy weight of the metal. For storage in large-scale power networks one thinks of the gas in high pressurised pipe-lines or underground caverns. All feasible but somehow a little unnerving; and the feeling remains that storage and transport is rather a weak point in the idea of the hydrogen economy.

A recent paper from the RCA Laboratories at Princeton in the US (Williams, Crandall & Bloom *Appl. Phys.* **33(5)** 381; 1978) suggests an interesting alternative. Linking the hydrogen to CO_2 to give formic acid, HCOOH, from which it can be released using a palladium catalyst, one obtains a stable liquid energy storage medium, equivalent, even with the formic acid as a $4\ \mathrm{mol}^{-1}$ (4 M) aqueous solution, to the gas held at 100 atm pressure in a heavy cylinder. The acid can be made electrolytically in the 4 M solution by the reduction of CO_2 (or bicarbonate ions, HCO_3^-) with oxygen appearing at the other electrode. Using an amalgamated nickel electrode for the CO_2 reduction with an ion exchange membrane to separate it from the oxygen electrode the authors observe only an extremely small current ($1\ \mathrm{mA\ cm}^{-2}$) even with a high overpotential (1.0 V) denoting a very low electric energy to hydrogen conversion efficiency and a low specific output—which implies a very large investment in electrolysis plant. On such a basis the conversion cost would be prohibitive even without taking account of the palladium hydrogen release catalyst. And that is not cheap; a simple calculation suggests over £3,000 worth of palladium-carbon at current prices to liberate enough hydrogen to power a small motor car (3.5 kW electrical output). But such calculations are mischievous—the authors have made a laboratory demonstration of the process, not a pilot plant demonstration unit.

A. B. Hart is at the Central Electricity Generating Board Research Laboratories, Leatherhead, UK.

0028–0836/79/0277—0015$01.00

It is the basic idea of going directly from electricity to a stable liquid energy storage medium which is so exciting. Further work must examine what energy losses are inevitable in the formic acid system to see whether they can be accepted and whether other losses can be avoided at acceptable cost. Electrochemical studies must also show whether by working under different conditions, for example, at higher temperatures and pressures, one could achieve a higher concentration of the acid (a 60% solution would contain more than half as much hydrogen on a volume basis as liquid hydrogen itself). It is by no means evident that the electrolytic liberation of hydrogen atoms in close proximity to CO_2 molecules, leading to the formation of HCOOH, should not at a suitable surface, proceed as efficiently at a given surface-specific rate as in the absence of CO_2. In this case the atoms form hydrogen molecules, as in the electrolysis of water to form hydrogen gas at the cathode. And advanced electrolysis of water can achieve a high (75–90%) efficiency of conversion of electrical energy into hydrogen (expressed as the heat of combustion to water), vastly higher than the authors' experiments seem to suggest for formic acid formation. A review of the electrochemical literature (Russell *et al. J. Electrochem. Soc.* **134,** 1329; 1978) suggests that the authors' low efficiencies and low specific rates of formic acid formation are expected for this type of electrode process, where the hydrogen atom must be liberated at a high over-voltage (also with very poor electrical efficiency) to be able to break open the CO_2 molecule and react with it. One might get over this problem but it is apparent that considerable research is needed.

Meanwhile, it may certainly be reasonable for the authors to claim, as they do, that the system "represents an energy storage method of exceptional versatility and generality" but until much more work is done it is surely rather over-optimistic to state that it "will be important for the storage of elecrical energy whenever there are surpluses". □

European plant health

from a Correspondent

THE introduction of plant pathogens into a country in which they are not normally present can have devastating economic or environmental consequences. To prevent the inadvertent introduction of serious pathogens, stringent and well-informed quarantine regulations are necessary. New quarantine measures for continental Europe and Britain have been proposed by the European and Mediterranean Plant Protection Organisation (*EPPO Bull*, special issue 1975) and the EPPO have recently published the first set of data sheets on which these recommendations are based (*EPPO Bull.* 8(2); 1978). These data sheets list some of the organisms covered by the quarantine regulations which are classified as A1 (organisms not present in the EPPO area) and A2 (present in the EPPO area). They provide a description of the pathogens and some of the diseases they cause.

At first glance this appears a commendable piece of work, but is it? One deficiency, which has caused widespread concern amongst plant pathologists who have the task of interpreting the regulations is that variations in strain, race and serotype are ignored. The potential importance of such differences can be seen in British hedgerows, now lined with rows of dead elms as the result of the introduction of a variant strain of a pathogen already classified as endemic within Europe (including Britain).

With regard to the diseases with a viral aetiology the picture is confused by the lack of any reference to a definitive description of the virus such as the AAB/Commonwealth Mycological Institute Descriptions of Plant Viruses, and by the omission of any description of the morphology, composition, grouping or serological grouping of the virus. How then is anyone to know exactly which virus is being referred to and in that case how can "an EPPO country take whatever action is necessary and reasonable to prevent introduction" (*EPPO Bull.* 1975 special issue).

Plant virus nomenclature is notoriously confused by the practice of naming the viruses after the disease they cause and it seems a shame that the EPPO have not learnt this lesson. For example they describe Scottish raspberry leaf curl as a 'completely different disease' from American raspberry leaf curl and attribute rose wilt syndromes to endemic A2 pathogen(s) when plainly this is unlikely to be the case.

In Britain and Holland no clear evidence that rose wilt or dieback was graft transmissible has been found (*Phytopath Z.* **79,** 160; 1974; *Neth. J. Pl. Path.* **81,** 187; 1975); whereas in New Zealand the pathogen was readily graft transmitted and some field spread has been recorded (*N.Z.J. agric. Res.* **14,** 735; 1971; *A. J. R. N. Z. Inst. Hort.* (2), 16; 1974). In California rose spring dwarf (*Pl. Dis. Reptr.* 55, 294; 1971) was reported and described as a graft transmissible disease distinct from rose wilt (*Pl. Dis. Reptr.* **60,** 183; 1976). In addition rose leaf curl, a distinct component of a disease complex which resembles rose wilt, has also been described in California (*Pl. Dis. Reptr.* **60,** 178; 1976). The question therefore remains of what is rose wilt and which pathogens cause it. Poor graft union formation, stunting and proliferation are disorders that can be induced by many pathogens, physiological conditions and environmental factors in woody plants. In view of this, to suggest endemic A2 pathogenic causes and to recommend quarantine procedures on that basis is both naive and foolhardy. Quarantine procedures should be based on the aetiology of a disease, not on disease expression.

The EPPO Working Party also seems to be rather inconsistent in its recommendations for the control of A1 pathogens. For the control of needle cast of Japanese larch caused by *Mycosphaerella larici-leptolepis* they state that "the importation of larch from Japan should be prohibited". However, in respect of American plum line pattern virus they say that it is doubtful whether roguing of trees should be recommended. This contradicts the original recommendations for A1 organisms of taking necessary and reasonable action to prevent entry.

The lists of A1 and A2 pathogenic organisms are abysmally short when one considers the vast numbers of economically important pathogens that have been described throughout the world. It is to be hoped that EPPO will rapidly extend their lists and that the data sheets will provide more comprehensive and accurate information on these pathogenic organisms.

Quarantine measures can only be effective if those responsible for them are well informed. Bureaucrats with little understanding of plant protection must seek the guidance of leading research workers otherwise confusion will result.

Non-endemic pests and pathogens are being imported to Britain annually, and the situation in continental Europe is even worse. EPPO's function is to advise on the restriction of movement of pathogenic organisms into and within Europe without impairing plant trade. Let us hope that it will adopt the correct policies to fufil this role and not imitate the Plant Health Branch of our own Ministry of Agriculture, Fisheries and Food (see *Nature* **259,** 449; 1976).

review article

Present status of γ-ray astronomy

K. Pinkau

Max-Planck-Institut für Physik und Astrophysik, Institut für extraterrestrische Physik, D-8046 Garching, FRG

Diffuse extragalactic γ-ray flux may be due to individual objects, and two possible sources are 3C273 and NGC4151. The Milky Way is an intense line source exhibiting a large contrast in emissivity between the directions towards and away from the galactic centre, respectively. γ-ray point sources and cosmic rays interacting with interstellar material are both responsible for this emission—the latter decreasing away from the centre. Twenty-one point sources have been discovered to date, including four pulsars which all have two maxima with ~0.4 phase separation. If the number and position of γ-ray point sources are proportional to the stellar birth rate, the bulk of the galactic emission can then be explained by 5,000 sources emitting the 10^{42} *photons* $>100\,\mathrm{MeV\,s^{-1}}$ *produced in the galaxy.*

THE new discoveries by ESA's satellite Cos B (refs 1–3) and successful[4] balloon observations provide new material for a discussion of the astrophysical processes leading to γ-ray production. The sky in the light of γ rays shows two distinct features, a general and rather diffuse flux from extragalactic space against which the narrow and brilliantly luminous band of the Milky Way stands out.

γ Rays from extragalactic space

The cosmos is filled with photons of all wavelengths. If one considers an average point in intergalactic space, the energy density of photons in the various energy bands is like that shown in the hatched area[5] of Fig. 1; the full line represents the energy density in photons from the Galaxy in the solar neighbourhood. Remarkably the energy density in metagalactic space remains at the high level of several $10^{-5}\,\mathrm{eV\,cm^{-3}}$ in the X- and γ-ray domain. This is because hard X rays and γ rays are practically not absorbed[6] (the redshift, at which the cosmos becomes opaque to γ rays is $z \sim 100$) and distant sources therefore make a similar contribution to the diffuse flux as close ones. Thus, extragalactic γ-ray astronomy must be considered with cosmological questions.

Observationally, there seems to be agreement about the shape of the energy spectrum of the diffuse radiation[7–9]. Figure 2 shows a shoulder at around 3 MeV which steeply drops beyond 10 MeV. The data at lower energies accord well with the results at high (>50 MeV) energies, if allowance is made at high energies for a flat galactic contribution to the extragalactic flux.

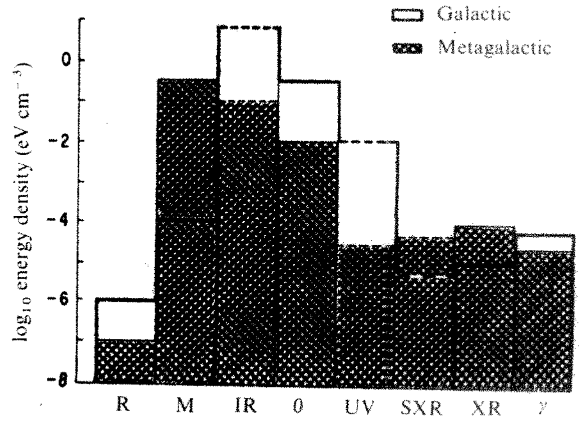
The origin of the diffuse radiation in general and the shoulder at 3 MeV in particular is still unclear; is it due to a truly diffuse mechanism, or to an as yet unresolved superposition of many individual sources? We encounter the same problem when we consider the origin of galactic γ rays.

This uncertainty has been due to, on the one hand, the little observational evidence available on the γ-ray luminosity of galaxies, quasars and other objects, and on the other hand, the models for truly diffuse production either in intergalactic space now or during the big bang have free parameters. It has thus been possible to reproduce the same observational results with several different models. For example, the diffuse radiation could originate from electrons that escape from galaxies into intergalactic space, or at least the shoulder could be caused by redshifted photons from π^0-decay that in turn have been produced either by a copious supply of cosmic rays in the big bang, or by simultaneous baryon–antibaryon annihilation[5,10].

Some new light has been shed on this situation by the observations of two extragalactic γ-ray sources[3,4] which have been identified to be 3C273 and the Seyfert galaxy NGC4151. If these identifications are correct, 3C273 would emit $2\times10^{46}\,\mathrm{erg\,s^{-1}}$ in 50–500 MeV γ rays, and the spectrum of NGC4151 would look like that shown in Fig. 3. Certain assumptions about space density and luminosity, the diffuse γ ray background could then be explained by a superimposition of individual sources[4].

These new discoveries have directed attention towards extragalactic γ ray astronomy for other reasons. One possible mechanism for producing the sharp cut-off in the spectrum of NGC4151 at 3 MeV is the Compton process[11]. Due to large energy losses, a sharp cut-off will have been generated in the energy spectrum of the electrons required to scatter photons into the γ-ray domain which then reproduces itself in the spectrum of NGC4151. If this were true, the position and shape

Fig. 1 Energy density of the cosmic photons. The hatched area shows the energy density of photons in the various energy bands (radio, R; microwave, M; infrared, IR; optical, O; ultraviolet, UV; soft X ray, SXR; X ray, XR; and γ ray band) in metagalactic space; the full line shows the galactic contribution evaluated in the solar neighbourhood. After Silk[5].



0028–0836/79/0277—0017$01.00

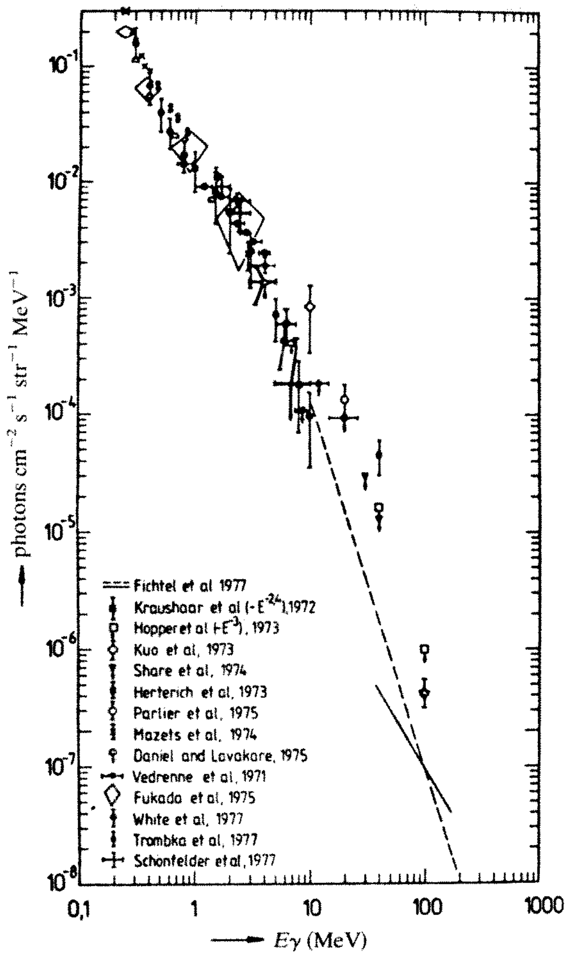


Fig. 2 Energy spectrum of the diffuse γ radiation after Schönfelder *et al.*[7], Fichtel *et al.*[8] Taken from ref. 9. The solid line is the contribution of galactic γ rays to the total diffuse flux from high galactic latitudes, the dashed line is the remaining extragalactic flux if the galactic contribution is subtracted from the total diffuse spectrum.

of the cut-off must be highly time-variable[12] and it would give some indication of the energy requirement and rate of occurrence of events that power Seyfert galaxies like NGC4151.

γ Rays from the Galaxy

The galaxy appears as a narrow line source in high-energy γ rays, its width at half maximum[13] is $+3° \geq b^{\mathrm{II}} \geq -2.5°$ at $l^{\mathrm{II}} = 0°$, and $+7° \geq b^{\mathrm{II}} \geq -3°$ at $l^{\mathrm{II}} = 120°$. (The significance of this deviation from the galactic plane would be interesting to consider.)

Quantitatively, the line source strength of the galaxy is shown[13] in Fig. 4. This is an old picture: although the galactic survey has been completed by Cos B, but the new data have not been published yet. However, in the complete data set, regions of intense γ-ray emissivity in the plane seem to occur when the line of sight tangentially intersects spiral arms which in turn have been localised by high excitation parameter H II regions and intensity maxima in the radio continuum and neutral hydrogen[16].

γ-ray point sources are also embedded in the galactic plane. Their positions (and identifications, if any) are indicated by arrows in Fig. 4. A list of point sources is given in Table 1 (refs 17, 18). The nature of the galactic γ-ray emission has been widely debated. γ rays originate from the interactions of cosmic-ray nucleons and electrons with interstellar matter, yet the observed line source strength shown in Fig. 4 in the direction towards the centre differs strongly from the fluxes expected in a simple model where cosmic rays (with the average galactic intensity as observed near the Solar System) interact with interstellar atomic hydrogen. These expected fluxes would not vary much as a function of longitude, because the projected density of atomic hydrogen along the line of sight also is rather constant. In this simple model, the γ-ray line intensity over the entire longitude range would be that indicated by the dashed lines in Fig. 4. Clearly, many more γ rays come from the longitude interval between ±60° than can be explained by this simple model[19].

One way of explaining this discrepancy would be to assume that more material and cosmic rays are available in the inner parts of the Galaxy. On the other hand, γ rays also originate in point sources. Can they account for the difference? The discussion is complicated by the fact that the angular resolution of a γ-ray telescope (several degrees) is insufficient to directly answer these questions.

Discrete sources

The truly diffuse component is that part of the galactic radiation that remains if point sources are subtracted. It is therefore necessary to consider these first.

γ-ray point sources are of high astrophysical interest in their own right and indeed the impact of γ-ray astronomy on the whole of astrophysics may eventually be larger here than in the study of the regions of residence of cosmic rays in the Galaxy.

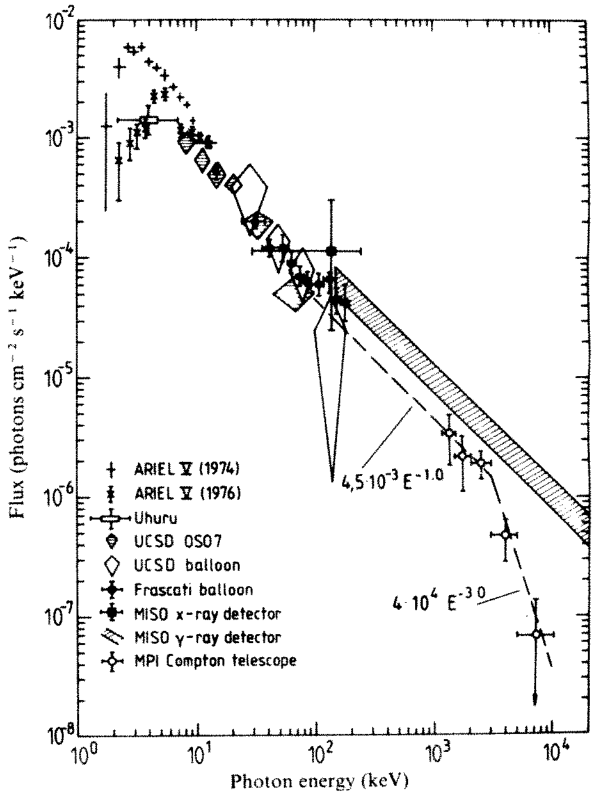

Fig. 3 The energy spectrum of γ rays from the direction of NGC4151. After Schönfelder[4]. The MISO γ-ray detector actually measured an integral flux > 150 keV and not a spectrum. The hatched area represents the spectrum derived by these authors, and compatible with their integral flux under the assumption of an $E^{-1.0}$ power law extending to infinity. It thus does not conflict with the measurements of the MPI Compton telescope.

Due to the limited angular resolution, point source identifications in the Galaxy have been possible only for pulsars[20,21], the number of which has now been increased due to Cos B to be four[22–24]: PSR1822 − 09, PSR0531 + 21, PSR0740 + 28 and PSR0833 − 45. It is very surprising that all four pulsars show double maxima with a phase separation of 0.4 (Fig. 5), although their energy spectra are different.

Furthermore, the luminosities of the four pulsars (using the dispersion measure as distance indicator) do not decrease in

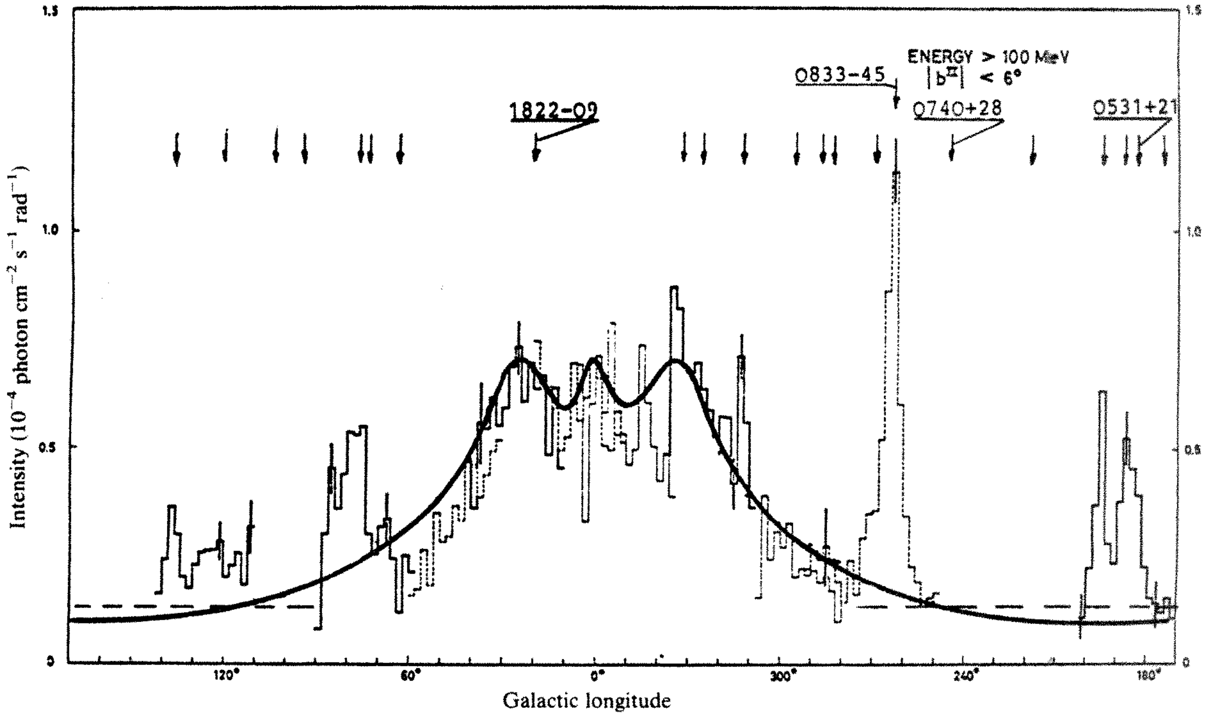

Fig. 4 Longitude profile of the intensity of γ rays of energy >100 MeV over the latitude range $|b^{II}| < 6°$. The dashed line roughly indicates the line intensity expected from cosmic rays interacting with interstellar gas in the region $l^{II} = 180° \pm 80°$ after Fichtel *et al.*[14], allowing for the narrower latitude range $|b^{II}| < 6°$. The solid line is the distribution in apparent brightness of O-stars as given by their Lyman-continuum flux after Mezger[15]; it has been normalised to the average line intensity of $\sim 10^{-5}$ photons >100 MeV cm^{-2} s^{-1} rad^{-1} contributed by the Cos B point sources from the two viewing periods centred on 126° and 185°, respectively.

proportion to decreasing $\dot{P}/P^3$ which in turn is proportional to $\dot{E}$, the rate of loss of rotational energy (assuming the same momentum of inertia in all four pulsars). Thus, at least in the four cases observed (which may be subject to selection effects), the efficiency of converting $\dot{E}$ into γ-ray luminosity increases with decreasing $\dot{E}$ until some as yet unknown limit is reached[23–25].

Finally, at least in the case of the Crab (0531+21) and Vela (0833−45), the emission from these sources is compatible with it being entirely pulsed. The 2σ lower limit of the pulsed fraction is 78% (>50 MeV, Crab) and 91% (>50 MeV, Vela), respectively[22].

Attempts have been made to identify at least some of the Cos B sources with other objects[17] like X-ray sources[26,27], radio-optical sources, supernova remnants[28], H II-regions[29], and dark clouds[30] (which radiate γ rays if they are penetrated by cosmic rays). Due to the large positional error in the γ ray observations, these have remained possibilities.

General galactic emission

In the outer parts of the Galaxy, γ rays are clearly produced by both, cosmic ray interactions with interstellar matter, and point sources. A cosmic-ray gradient away from the galactic centre must exist[43], because the γ-ray intensity seen from the outer parts is less than that expected if cosmic rays were to fill the entire galactic disk with the same intensity as that near the Solar System.

Whether or not the high flux value of γ rays from the inner parts of the galaxy is due to point sources or a truly diffuse process requiring more interstellar material and/or more cosmic rays there, is as old a question as the first positive results of γ-ray astronomy[19,31].

It has been shown[19] that the radio emissivity, the distribution of neutral and molecular[32,33] hydrogen alone do not sufficiently well represent the spatial distribution of general γ-ray emissivity in the Galaxy. Consequently, one has to construct the population of γ ray emissivity theoretically by assuming a correlated variation of cosmic-ray energy with matter density, be it in the spiral arms[14], or in a ring of high matter density as provided by molecular and atomic hydrogen[33].

These models of the galactic γ-ray emissivity have been constructed so that they can explain quite well the observational results. But they are not conclusive because the actual amount of interstellar material available as an interaction partner for cosmic rays, and the actual intensity of cosmic rays throughout the galactic plane are uncertain. Therefore there is still the possibility that the observed picture of our Galaxy in high energy rays could be dominated by point sources, γ-ray stars, rather than diffuse processes. Because individual γ ray sources cannot be resolved in an environment of large emissivity, and time variability may help identification in many but probably not all cases, many statistical arguments have been used with conflicting results. For example, Ögelman[34] attempted to explain the OSO 3 results by extrapolating the intensity of known X-ray sources into the γ-ray domain using a −2.0 power law index; the uncertainty of such a method was pointed out by Clark *et al.* [19]. Similarly, Coe *et al.*[26] extrapolated the apparent brightness of X-ray sources into the γ-ray domain, using the 4th Uhuru catalogue and Ariel 5 observations. They used their results to calculate an average for the galactic γ-ray emission by point sources, while Protheroe *et al.*[35] came to the conflicting conclusion that γ-ray point sources, based on a comparison with the 4th Uhuru catalogue, could account only for 19% of the galactic line emission.

The situation is also unclear if pulsars are used to estimate the possible contribution of point sources. For example, Kniffen *et al.*[36] estimated the pulsar contribution to galactic γ rays at 5%, while Higdon *et al.*[37] believe that a much larger contribution could be expected.

The problem with statistical arguments is that a known population is required, that has the same spatial distribution within the galaxy as that expected for the γ-ray sources. It has not been shown that the X-ray sources provide such a population. There are indications that the distribution of pulsars in the galactic plane[38] may be quite similar to the γ-ray emissivity.

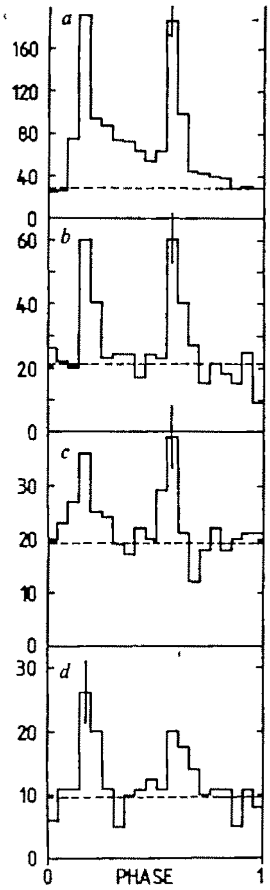

Fig. 5 Light curves of the four pulsars now observed by Cos B (refs 19–21): *a*, PSR0833−45; *b*, PSR0531+21, *c*, PSR1822−09, *d*, PSR0740−28

A statistical investigation of this question may start from the observations of point sources in the anticentre direction, assuming that all have been discovered in favourable conditions of observation, namely low background and low space density of sources which then allows detection in spite of the low power of angular resolution of the γ-ray telescope (several degrees). One then may extrapolate this result to cover the entire galactic plane, scaling it according to the variation of a known population of astronomical objects which are believed to have a similar space dependence as γ-ray sources. Attempts using X-ray sources or pulsars have led to conflicting results.

One may, however, investigate whether γ-ray point sources could be young objects and thus be correlated to the stellar birth rate. It had been noted (see, ref. 41) that the distributions in the galactic disk of H_2, H II-regions, γ rays and supernova remnants are all similar. However, the question of the stellar birth rate has recently been reviewed[39,40] and has quantitatively been estimated by counting the number of Lyman continuum photons emitted by O-stars per element of volume of the galactic disk. From observations of giant radio H II-regions[39] and the extended low density H II-regions, Mezger[15] was able to derive the emissivity of the galactic disk in Lyman continuum photons as a function of galactocentric distance.

It is proposed here that the spatial distribution of γ-ray localised sources closely resembles that of the O-stars, that is that of the Lyman continuum photons (Fig. 6). The width of that layer in the galactic plane is very narrow, ±100 pc, in agreement with the narrow width of the galactic γ-ray emissivity.

One may now construct the line source intensity of apparent brightness of the Lyman continuum photons by using the data of Fig. 6 and integrating along the line of sight through the galactic plane, taking account of the limited thickness of the disk: this is the full line of Fig. 4 and it supports the conjecture that the population of O-stars has the same spatial distribution as the γ-ray emissivity.

Figure 4 shows a rough comparison which is circumstantial in the sense that Mezger[15] unravelled observational results to arrive at the galactic production rate of Lyman continuum photons which then had to be reconverted to the distribution of apparent brightness along the line of sight (Fig. 4). However, a detailed comparison of extended low-density H II- and radio H II-regions with the γ-ray sky map (which will be forthcoming shortly from the Cos B observations) may reveal a much greater agreement in detail. Already, correlations between Cos B point sources and H II-regions have been noted[29,32], and the spiral structure, which also is visible in the γ-ray sky surveys, is in turn delineated by H II-regions[16]. Also, 74% of the Lyman continuum emissivity is estimated to come from the main spiral arms, yet only 13% from the interarm region, and 13% from the galactic centre[39]. Thus, if more γ rays are found to come from spiral arms[14], it may be because the γ-ray point sources have a larger density there.

Approximately, then, 3×10^{11} Lyman continuum photons are emitted per single γ ray with energy exceeding 100 MeV, corresponding to a galactic luminosity of 10^{42} (γ's > 100 MeV s^{-1}). In other words roughly 10^{49} γ rays above 100 MeV are produced per birth of one solar mass.

These considerations may now be applied to an investigation of the relative importance of point sources and diffuse emission.

Table 1 γ-ray sources detected by Cos B

The information is preliminary; analysis continues. Error circles for positions have radii between 0.5° and 2.0°. With the exception of CG263-2 source intensities (>100 MeV) are within the range 0.2 to 1.0 times that of CG185-5. Spectral clarification is based on the relative numbers of photons detected in the ranges 50 to 150 MeV and >150 MeV. The pulsar identifications are confirmed by timing phase analysis. Sources marked X are located in complex regions where more detailed analysis is needed to provide information additional to that given in the first Cos B catalogue.

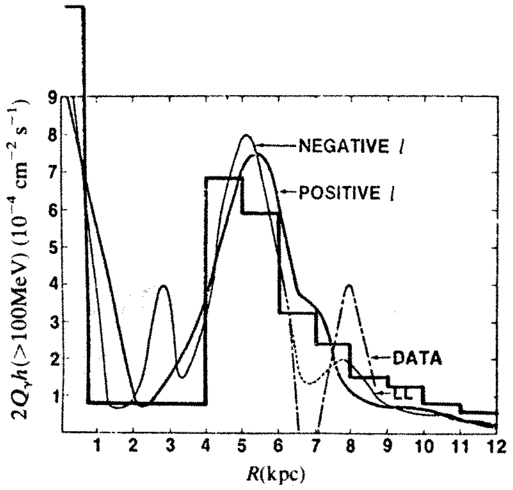

Fig. 6 Modified from Stecker[32], the smooth lines being the result of an unfolding of γ-ray line intensity data assuming cylindrical symmetry of γ-ray emissivity in each half of the galaxy. (Compare also Strong *et al.*[42]). The histogram represents the source function of Lyman continuum photons after Mezger[15], if 3×10^{11} Lyman continuum photons are produced per γ ray >100 MeV.

Figure 4 shows that the Lyman continuum population has nearly the same apparent brightness for the longitude interval $l^{\text{II}} = 180° \pm 80°$. Two Cos B observation periods[17] centred at $l^{\text{II}} = 126°$ and 185° fall within that longitude. During each viewing period, an angular interval of ~0.6 rad in longitude was observed.

There are six point sources with, five without the Crab in both angular intervals (including one source at $b^{\text{II}} = 7°$), leading to a contribution of point sources of 1.4×10^{-5} photons >100 MeV $\text{cm}^{-2}\,\text{s}^{-1}$ with, and 10^{-5} photons >100 MeV $\text{cm}^{-2}\text{s}^{-1}$ without the Crab. In both regions, an angular width of ~1.2 rad was scanned, thus the line source contribution of point sources is $\sim10^{-5}$ photons >100 MeV $\text{cm}^{-2}\,\text{s}^{-1}\,\text{rad}^{-1}$.

One may now scale the number of γ-ray point sources and their apparent brightness according to the stellar birth rate, that is the apparent brightness of O-stars as given by the solid line of Fig. 4. This line has been normalised to the value of $\sim10^{-5}$ photons >100 MeV $\text{cm}^{-2}\,\text{s}^{-1}\,\text{rad}^{-1}$ at the two viewing directions of Cos B used above. Figure 4 shows that the flux of these point sources can fully explain the shape and enhancement of the γ-ray line source towards the galactic centre.

On the other hand, one may argue that it is the cosmic-ray density that scales like the stellar birth rate, and not the number of γ-ray point sources. In the regions of normalisation used above, the contribution of cosmic ray interactions with interstellar matter is of the order of 1.3×10^{-5} photons >100 MeV $\text{cm}^{-2}\,\text{s}^{-1}\,\text{rad}^{-1}$ (ref. 14) if one takes account of the latitude range $|b^{\text{II}}| < 6°$. The average contribution of point sources to the combined flux of $\sim2.3\times10^{-5}$ is then 43%. Had the distribution in apparent brightness for O-stars been fitted to the value for cosmic ray produced γ rays alone, a value of 9×10^{-5} photons $\text{cm}^{-2}\,\text{s}^{-1}\,\text{rad}^{-1}$ would have been predicted for the galactic centre region (somewhat high (Fig. 4)), and 1.6×10^{-4} photons $\text{cm}^{-2}\,\text{s}^{-1}\,\text{rad}^{-1}$, if one had normalised to the total flux of 2.3×10^{-5} (much too high; see Fig. 4).

Thus one may scale only one of the two components, cosmic ray interactions or point sources, but not both. Therefore, one will have to argue either (as refs 14, 33, 35–37, for example) that the point source contribution remains at a comparatively low level throughout the galaxy, and the γ-ray emissivity through cosmic-ray matter interactions scales like the stellar birth rate, or one may hypothesise that the γ-ray point sources are correlated with the stellar birth rate which then requires that the cosmic ray produced γ-ray emissivity remains at a low and perhaps even constant level throughout the galaxy. If one considers the consequences of the second hypothesis, that it is the point sources which follow the stellar birth rate, then 7–8 γ-ray point sources would have been expected to lie within the Cos B viewing direction centred at 74°, while only three have yet been discovered[17], and 14 should have been visible during the observation period centred at 322°, yet again only three have been seen[17]. 20 point sources would be expected from an observation period directed towards the galactic centre. As the longitude interval of any Cos B observation period is only ~30° wide one can clearly understand, why the γ-ray instrument cannot resolve these sources. Also, the large number of sources that are expected to lie within any viewing direction may account for the fact that the energy spectra as measured by Cos B do not change significantly as a function of galactic longitude[2].

Hermsen *et al.*[17] argued that the individual γ-ray point source has a luminosity of $\gtrsim10^{35}$ erg s^{-1}, then approximately 5,000 point sources in the entire galactic disk are required to produce the bulk of the 10^{42} photons s^{-1} above 100 MeV that the galaxy emits.

The considerations made above, of course, just demonstrate a possibility, albeit an interesting one. They are, first limited by statistics as there is a 40% error in six point sources. Second, it is a hypothesis that γ-ray sources are correlated to the stellar birth rate and thus to the population of O-stars, and that in addition such a correlation can be extrapolated from the outer regions $l^{\text{II}} = 180° \pm 80°$ to the entire galactic disk.

On the other hand, the suppositions made here provide a powerful stimulus for further observational and theoretical investigations if such a correlation can be substantiated, and what the physical reasons behind it are.

A new atom identification and detection technique for ultrasensitive mass spectrometry has been applied to the radionuclide ^{36}Cl. Measurements of the ^{36}Cl/Cl ratio in AgCl precipitated from six different natural water samples fell in the range 1.2×10^{-13}–2×10^{-12} with a background level below 3×10^{-15}. For each sample 70 mg of AgCl was used, requiring 1–5 l of water.

CHLORINE-36, the longest lived radioactive isotope of chlorine, is continuously being produced in the atmosphere. In contrast with atmospheric ^{14}C, which forms a large reservoir as gaseous CO_2, ^{36}Cl leaves the atmosphere in rain and enters the hydrosphere directly. Due to the low rate of exchange with solids, the soluble chlorides containing ^{36}Cl form an effective tracer in groundwater hydrology, and it has been suggested that the 308,000 yr half life would make it a promising clock for a chronology that could cover the entire Pleistocene era[1]. Recently, the advantages of using ^{36}Cl to study groundwater were stressed[2] in connection with establishing the suitability of underground sites for the storage of nuclear wastes. However, before a ^{36}Cl chronology can be established, the origin and production rates of ^{36}Cl must be determined accurately and the measured concentrations related to hydrogeological and palaeoclimatological data. Such detailed and difficult studies should be stimulated by a demonstration here that ^{36}Cl can be detected in small samples with sufficient sensitivity.

The few measurements of ^{36}Cl in environmental samples published to date have been made by counting β emissions from the radioactive decay. Such experiments are difficult because of the low counting rates resulting from the long half life of ^{36}Cl. In addition, it is difficult to distinguish the β rays of ^{36}Cl from those of trace quantities of other radionuclei in the sample because of their low energy[3]. Tens of grammes of chloride taken from thousands of litres of water are required to give counting rates distinguishable above the background and even then counting times as long as a week are required. This article describes the first successful application of the Rochester MP tandem van de Graaff accelerator system as an ultrasensitive mass spectrometer[4–6] to the problem of determining the ^{36}Cl/Cl ratio in tens of milligramme chloride samples taken from 1 to 5 l of water from various sources. For the 45 mg background sample of zone refined AgCl reagent a concentration of $<3\times10^{-15}$ was determined, equivalent to an activity of about 1 β ray yr^{-1}.

To use ^{36}Cl for dating groundwater, the input of ^{36}Cl must be determined for a region and assumed to be relatively constant in the past. Atmospheric ^{36}Cl originates from interactions of cosmic rays and their secondaries with ^{40}Ar and ^{35}Cl, from nuclear explosions, and possibly from the influx of meteoric dust. At the surface of the Earth ^{36}Cl is produced through the activation of ^{35}Cl by cosmic ray secondary neutrons and in the subsurface by neutrons from the natural radioactivity in uranium and thorium deposits[7]. To use the ^{36}Cl/Cl ratio, the dilution from old chlorine must also be understood. Atmospheric chlorine arises primarily from ocean spray, while additional chlorides enter groundwater from dissolution of salt deposits. Measuring the ^{36}Cl/H_2O ratio instead of the ^{36}Cl/Cl ratio corrects for an unknown dilution by old chlorine, but uncertain precipitation and evaporation rates complicate the analysis. Although some progress has been made in predicting quantitatively the above origins of ^{36}Cl and Cl in water, it is beyond the scope of this paper to discuss them in detail.

The samples studied, listed in Table 1, were chosen partly to cover a wide range in expected ^{36}Cl content and partly for reasons of convenience. the Rillito River sample, taken from a well near an ephemeral stream, is largely runoff from recent rainwater and is therefore expected to contain a high ^{36}Cl content from nuclear explosion tests. In an attempt to exclude the bomb input source, a sample was obtained from a deep well near Tucson, Arizona that had been estimated[8] by means of tritium and ^{14}C analyses to be more than 2,000 yr old. As dilution from old salt deposits was also expected to be low, the ^{36}Cl/Cl ratio in this sample should provide a direct indication of the cosmic ray production rate in the atmosphere—the most important result required for establishing a ^{36}Cl chronology. Also studied were two samples from the Lake Ontario water intake of Eastman Kodak, a reagent grade sample that presumably originated in a mine (and thus should contain little ^{36}Cl), and two samples artificially enriched in ^{36}Cl.

Separation and identification of interfering isotopes

The methods and results for atom identification and detection of ^{14}C in natural samples were discussed in detail at a recent conference on radiocarbon dating[9], where the first detection of

0028–0836/79/0277—0022$01.00

^{36}Cl, using a tandem accelerator[10], and an attempt to detect ^{36}Cl using a cyclotron[11] were also reported. The present apparatus (Fig. 1) incorporates some important improvements over that used for the ^{14}C measurements[13] which were found to be necessary to resolve the more closely spaced isotopes at the higher mass. An advantage of accelerating ^{36}Cl to energies above 1 MeV AMU^{-1} is that the atomic number Z can be identified by measuring the rate of energy loss of the ion. This Z determination, combined with the usual selection of a specific mass-to-charge ratio M/q with a combination of magnetic and electrostatic analysers, allows complete and unambiguous isotope identification without the severe loss in sensitivity typical of conventional high-resolution mass spectrometers. Although this analysis is adequate for positive identification of ^{36}Cl, in practice, the counting rate in the detector arising from trace impurities in the sample was high enough to produce gain shifts in the detector and produce tails that overlap the ^{36}Cl peak.

The basic limitation in measuring small concentrations of ^{36}Cl with mass spectrometers is due to the necessity of separating ^{36}Cl from the isobars ^{36}Ar and ^{36}S and from mass 36 molecules. Although chlorine readily forms stable negative ions, which is a requirement for acceleration in a tandem van de Graaff, argon (a noble gas) does not. No evidence was seen for argon in the detector (<1 argon atom per 10^{14} chlorine atoms) indicating that either Ar$^-$ is not produced in the caesium sputter source or that it does not have a lifetime sufficiently long to reach the tandem terminal as a negative ion. Sulphur, however, forms negative ions almost as readily as chlorine, so, with a ^{36}S abundance of only 0.014%, a one p.p.m. sulphur impurity produces an interference at the 10^{-10} level. The great sensitivity of the present technique is illustrated by the fact that a 1 p.p.m. concentration, considered very low for a sulphur impurity, would still result in a ^{36}S count rate of 300 c.p.s. for typical conditions in this experiment. The range separation technique[14] is not applicable because sulphur has the longer range so that special sample preparation techniques[15] were necessary to reduce the sulphur content to <10 p.p.m. In addition, the heavy-ion counter[12] was modified to give a ^{36}S rejection rate of better than 10^6 to 1 (see Fig. 2).

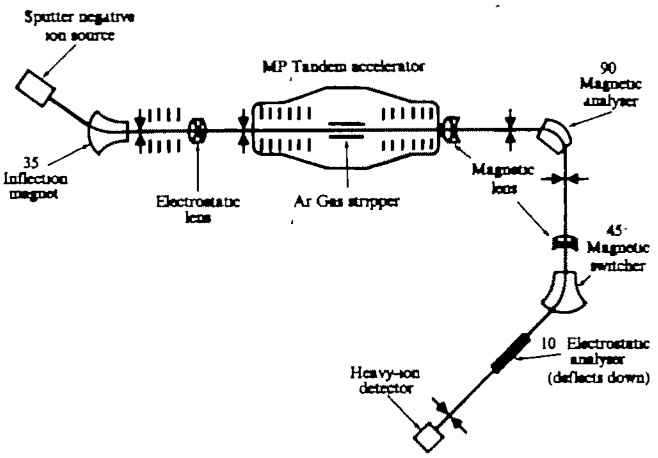

Fig. 1 Diagram of the apparatus used for ^{36}Cl measurements. From 5 to 13 μA of Cl$^-$ ions were produced from AgCl or NaCl samples in a caesium sputter source (model 834 HICONEX, General Ionex Corp.) the mass-36 negative ions were analysed by a magnetic inflection system ($M/\Delta M = 25$), accelerated to 170 KeV, then injected into the Rochester Mp tandem accelerator. At the terminal, which was held at 10.00 MV by a generating voltmeter stabilisation system. the ions were stripped of several electrons by argon gas, then accelerated again to ground potential. Charge state 7, mass 36 ions with $E = 80.17$ MeV were selected by a 90° magnet ($P/\Delta P = 600$), bent by a 45° magnet (which served to eliminate scattered particles), deflected 10° out of the horizontal plane by electrostatic plates ($E/\Delta E = 200$), and then analysed by a heavy-ion ionisation counter[12]. By increasing the inflection magnet and analysing magnet fields the ^{37}Cl beam could be switched onto the Faraday cup following the analysing magnet—the beam current measured here was used for normalisation.

Although interference from mass-36 molecules was eliminated by choosing a high charge state from the post-acceleration analysis system, atomic fragments that result from breakup of the mass-36 molecules at the terminal are not separable from ^{36}Cl in the magnetic and electrostatic analysers if they happen to have the same value of M/q after acceleration as the ^{36}Cl ions. For example, the $^{12}C_3^-$ molecular ion, known to be produced in nA quantities[18] by sputter sources, will behave exactly as ^{36}Cl^{6+} in electric and magnetic fields when stripped to ^{12}C^{2+} in the terminal. Although these carbon ions could be distinguished by their energy loss in the detector, the counting rate would be excessive even for a very low level of carbon impurity. This type of background can be eliminated by choosing a charge state that has no common factor with 36, that is 5, 7, 11, 13 or 17. For 10 MeV chlorine in argon gas, the charge-state distribution peaks near 6 with a full width at half-maximum of about 3 charge units[18], thus leaving 5 and 7 as the only good choices. Charge-state 7 was chosen for its higher energy (80 MeV as opposed to 60 MeV for charge-state 5) allowing better separation from ^{36}S in the detector.

Other potential sources of interference are ^{35,37}Cl ions which are injected into the tandem from tails of the intense ^{35,37}Cl$^-$ beams at the ion source because of the limited resolution of the inflection magnet (^{35}Cl can also be injected directly as H^{35}Cl$^-$). Although most of these ions will leave the tandem at discrete energies that are not selected by the 90° analysing magnet, some will charge exchange a second time in the residual gas of the

Table 1 Results for ^{36}Cl measurements

Sample	Total run time (min)	Total ^{36}Cl counts	Number of runs	Concentration ^{36}Cl/Cl($\times 10^{15}$)	Activity (d.p.m. − kg Cl)	Cl/H$_2$O (mg^{-1} 1)	^{36}Cl/H$_2$O ($\times 10^6$) (atoms^{-1} 1)

Although a few hundred mg of AgCl was obtained from the natural water samples, only 16–66 mg was used in the ion source, and most of this remained after the experiment. Errors quoted are one standard deviation for several measurements. Specific activity is that expected based on the ^{36}Cl concentration measured. The approximate total chlorine concentration in the original water sample is given in the next to last column, followed by the ^{36}Cl concentration.

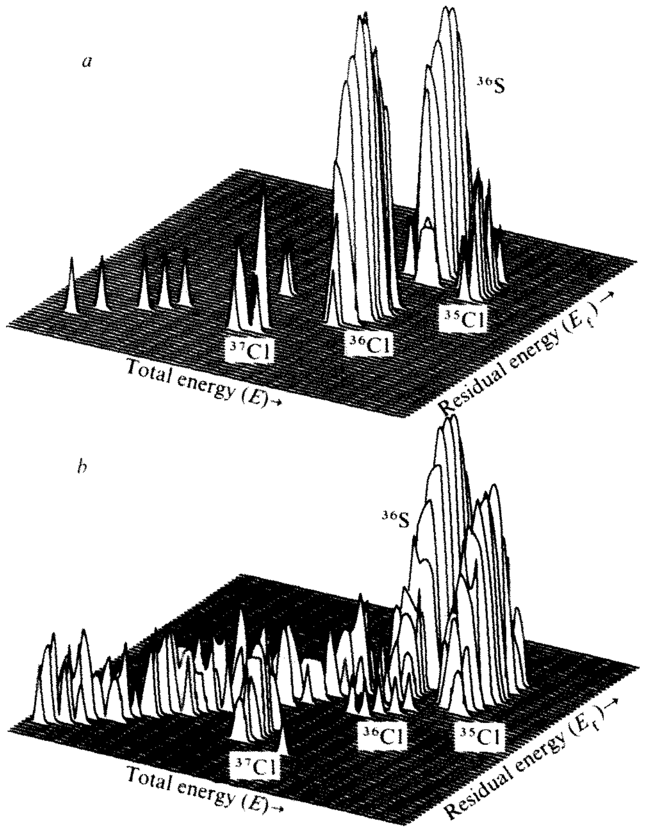

Fig. 2 Two-parameter logarithmic spectra for single runs on: *a*, a sample from Lake Ontario; and *b*, zone refined reagent grade AgCl. To help remove the effect of a high-energy tail arising from the Landau-Symon effect[16] on the intense ^{36}S peak in the energy loss spectrum (not shown), the heavy-ion counter[12] was modified to include four energy loss (ΔE) plates and a smaller residual energy (E_f) plate. In the computer, a digital window was placed on each of the first three ΔE signals at the expected location of ^{36}Cl. This reduced the effect of the tails since the high energy-loss events that produce them are not correlated among the different ΔE measurements. The events passing the three ΔE gates and an additional hardware E_f gate were plotted on the two parameter display of E_f against E shown. The long ^{36}S tail results from lower energy particles scattered into the counter. The zero has been offset on each axis.

acceleration tubes to produce $^{35,37}Cl$ ions with the same momentum and charge state as the ^{36}Cl ions. With only the ME/q^2 selection of magnetic analysers (all that is normally used with accelerators) the $^{35,37}Cl$ count rate was about 10^5 c.p.s. The intensity of this continuum was reduced more than 5 orders of magnitude with the E/q selection of an electrostatic analyser installed for these ^{36}Cl measurements (see Fig. 1). The remaining $^{35,37}Cl$ ions were easily resolved from ^{36}Cl in the detector.

Results and discussion

The results are given in Table 1. Normalisation for the $^{36}Cl/Cl$ ratio was obtained by reading $^{37}C^{7+}$ beam current before and after each ^{36}Cl measurement. As this current could not be monitored continuously, the accuracy of a measurement was limited by any fluctuations in the source output and accelerator transmission efficiency. The standard deviation of the $^{36}Cl/Cl$ ratios from several 10–20-min runs provided a measure of this uncertainty and was usually 10–15%, which is 2–4 times larger than the statistical error for single runs. In subsequent ^{14}C experiments the cycle period was decreased to 3 min, and this uncertainty, when calculated for the mean of several cycles, was reduced to about 3%. There is no reason that this level of uncertainty could not now be obtained for ^{36}Cl, where 3% corresponds to an age uncertainty of 13,000 yr.

The experimental method was checked by using two samples enriched in ^{36}Cl: the first was made by exposing reagent grade NaCl (BDH, lot no. 81515-7203) to an approximately known neutron flux from the University of Toronto Slowpoke reactor, the second by dilution of the first. The measured ratio of ^{36}Cl content, 74 ± 10, is in marginal agreement with the expected value of 100. This discrepancy would be resolved if the original reagent contained ^{36}Cl with a $^{36}Cl/Cl$ ratio as low as 30×10^{-15} (the ^{36}Cl content of the reagent used was not measured and was assumed to be negligible when determining the dilution factor of 100). A comparison between the absolute $^{36}Cl/Cl$ ratios is not useful because of the not-so-well known neutron flux. Clearly, more calibration checks need to be made before detailed hydrology studies are undertaken.

The low result for the zone-refined reagent-grade AgCl (Fisher catalog no. S174, lot no. 742272), demonstrating a sensitivity of three parts in 10^{15}, is probably the most significant result of this work. The sensitivity may be greater than this value as it could not be determined what fraction of the 32 counts collected was attributable to the ^{36}S tail (see Fig. 2) or how much was due to cross-contamination from other samples in the ion source. Even when considered as an upper limit to the sensitivity, the result shows that this technique is adequate for dating samples with ages up to 6 half lives or 2×10^6 yr. Memory effects and cross-contamination were shown to be small because the non-diluted enriched sample was run for ~ 4 h before experiments on the refined sample and so a dynamic range of almost 10^4 was realised.

Interpretation of the results for the neutral samples is difficult due to the present lack of detailed hydrogeological data, but H. Bentley helped us draw the following preliminary conclusions. Although the Rillito River sample was taken from groundwater, it is expected to be quite young—the higher ^{36}Cl content probably reflects input from nuclear testing in the atmosphere. Irrigation of nearby fields is indicated as the source of the high chloride content of the sample, and as this additional chlorine is atmospheric in origin, it may contain appreciable ^{36}Cl. The San Pedro River sample, on the other hand, is from surface water that is fed by groundwater springs—the relatively low concentration of ^{36}Cl may indicate that the bulk of this water is pre-bomb in origin. In contrast, the St David and Tucson well samples are certainly pre-bomb in origin[8]—these results should indicate the base atmospheric cosmic ray production for water that has not aged long compared to the ^{36}Cl half life. The Lake Ontario samples probably give a low $^{36}Cl/Cl$ result because of dilution from the great quantities of de-icing salt[19] used near the Great Lakes in the last decade. The $^{36}Cl/H_2O$ ratio, not affected by the de-icing salt, is small compared to the Rillito river value because of the higher precipitation and lower evaporation rates in the Great Lakes region as compared to Arizona.

In conclusion, the method described can be used to measure the ^{36}Cl concentration in a 100-mg sample of AgCl with an uncertainty of $< 10\%$ in less than 1 h. This performance should be adequate for studies using ^{36}Cl as a tracer in groundwater hydrology. Among other geophysical dating applications likely to benefit from the new technique is the study of deep ice core samples in Greenland and Antarctica[20]. Also, important information about the cosmic ray containment time within the Galaxy can be inferred from the number of the long-lived radionuclides ^{10}Be, ^{26}Al, ^{36}Cl, and ^{129}I present in the cosmic ray flux[21]. The concentration of these isotopes in Moon rocks[22] or meteorites[23] might be indicative of that flux, and a depth profile may give information on the cosmic ray energies.

We thank T. S. Lund and the rest of the NSRL staff for technical assistance, and Henry Lee, for experimental assistance, also Harold Bentley, for four Arizona samples, and Kenneth Harbison (Eastman Kodak) for preparing the fourth Arizona sample, the two Lake Ontario samples, and the zone refined AgCl. This work was supported by the NSF and in part by the NRC of Canada. R.P.B. is a Killiam Fellow.

Sm–Nd systematics of Lewisian gneisses: implications for the origin of granulites

P. J. Hamilton, N. M. Evensen & R. K. O'Nions

Lamont-Doherty Geological Observatory of Columbia University, Palisades, New York, 10964

J. Tarney

Department of Geological Sciences, The University of Birmingham, Birmingham, UK

Sm–Nd isotope systematics of Lewisian gneisses from North-west Scotland suggest that their igneous calc-alkaline precursors separated from previously undifferentiated mantle 2,920±50 Myr ago. Approximately 200 Myr elapsed before this material was finally differentiated and stabilised as granulite and amphibolite facies crust.

DURING the past decade, measurements of Sr-, Nd- and Pb-isotope ratios have demonstrated that ancient crustal segments are, in general, stabilised shortly after the separation of their igneous precursors from the mantle. For example, the initial $^{87}Sr/^{86}Sr$ ratios of the gneisses comprising many Archaean crustal segments are found to be close to the estimated mantle $^{87}Sr/^{86}Sr$ ratio for the time of their stabilisation, an observation which precludes more than ~100–200 Myr (refs 1-5) residence in a high Rb–Sr crustal environment. These conclusions, which are generally accepted amongst isotope geochemists, sometimes seem contrary to the geological complexity of such regions, as deduced from field observations and from the substantial geochemical changes which the igneous precursors must have experienced before they became structurally and thermally stable continental crust. Notable amongst these latter changes is the marked depletion of heat-producing elements (K, U and Th)[5–11] and some other lithophile trace elements[12–16] in granulite facies rocks.

The time interval between the initial generation of sialic material from the mantle and the eventual stabilisation of continental crust, during which these latter geochemical changes occurred, can only be broadly constrained by Rb–Sr and U–Pb techniques as indicated above. However, the successful application of the ^{147}Sm–^{143}Nd system to the dating of Archaean rocks[17–19] indicates that a combination of Sm–Nd, U–Pb and Rb–Sr studies may produce the time resolution required. The considerable amount of Rb–Sr (refs 4, 20–24) and U–Pb (refs 4, 10, 11, 24–26) geochronological data already existing for the Archaean Lewisian gneisses of North-west Scotland makes this a favourable location for an attempt to resolve this time interval.

The Lewisian gneiss complex forms the western foreland to the Caledonian orogenic belt, and crops out on the mainland of North-west Scotland, on the Outer Hebrides and several of the islands of the Inner Hebrides, and as large deformed slices within the Caledonian belt itself. Detailed geological field studies beginning with Sutton and Watson[27], geochemical studies[15,30], and numerous geochronological investigations using K–Ar (refs 24, 28, 29), Rb–Sr (refs 4, 20–24) and U–Pb (refs 4, 10, 11, 24–26) techniques have served to subdivide the Lewisian into three main regions. The central region contains pyroxene gneisses which have crystallised at high temperatures and pressures[31–33], and which record structural and chronological evidence for the earliest (Scourian) granulite facies metamorphism ~2,700 Myr ago. The northern and southern regions are composed mainly of amphibolite facies gneisses whose relationships with the central region granulites have been considerably discussed, but are now widely regarded as having occupied an initially higher structural level in the crust than the granulites[30]. The amphibolite facies regions record evidence of two later periods of deformation, metamorphism and igneous activity at ~2,200 Myr (Inverian) and ~1,700 Myr (Laxfordian). These metamorphic events have locally affected the central region granulites causing retrogression to amphibolite facies mineral assemblages[30,34]. The samples used for this study came from the central region, near the village of Drumbeg, Assynt, and from the northern region, near Rhiconich, and have been described elsewhere[15,30,35].

Of the large amount of geochronological data which now exists for various components of the Lewisian complex, the more pertinent recent data of reasonable precision are summarised in Table 1. The three zircon suites analysed by Pidgeon *et al.*[25,26] yield U–Pb concordia–discordia intercept ages that are almost within error at 2,700 Myr. This age is interpreted as dating zircon growth during Scourian metamorphism. These data define lower intercept ages corresponding to well-defined geological events, namely the Laxfordian and the Caledonian. Zircon data from Lewisian gneiss in the northern region, near Durness[24] are enigmatic, giving an older concordia–discordia age of 2,810 ± 50 Myr and a lower intercept age of 1,040 ± 50 Myr.

The Pb–Pb and Rb–Sr whole rock ages for Lewisian gneisses in Table 1, though of poorer precision, agree with the Scourian ages obtained from zircon studies.

Sm–Nd systematics

The Sm and Nd contents and $^{143}Nd/^{144}Nd$ ratios (Table 2) have been measured on 11 samples of Lewisian orthogneiss including

Table 1 Lewisian geochronologic data

Age* (10^3 Myr)	Samples	Locality	Method	Ref.
2.63 ± 0.14	Whole-rock amphibolite facies gneisses	Southern Outer Hebrides	Rb–Sr	4
2.60 ± 0.12	Whole-rock amphibolite facies gneisses	Southern Outer Hebrides	Pb–Pb	4
2.86 ± 0.20	Whole-rock amphibolite and granulite facies gneisses	Outer Hebrides and N, S and central regions	Pb–Pb	10
2.68 ± 0.06	Whole-rock granulite facies gneisses	Scourie	Pb–Pb	11
2.81 ± 0.05	Zircon size fractions from quartzo-feldspathic gneiss	Rispond, Durness, northern region	Concordia–discordia intercept	24
2.73 ± 0.01	Zircon size fractions from quartzo-feldspathic gneiss	Harris	Concordia–discordia intercept	26
2.66 ± 0.02	Two zircon suites from granulite facies gneisses	Kylesku, central region	Identical concordia–discordia intercepts	25

* Errors are quoted at the 2σ level. Ages here and in the text conform to the following decay constants:

$$\lambda^{235}\text{U} = 9.85 \times 10^{-10}\ \text{yr}^{-1};\ \lambda^{238}\text{U} = 1.551 \times 10^{-10}\ \text{yr}^{-1};\ \lambda^{87}\text{Rb} = 1.42 \times 10^{-11}\ \text{yr}^{-1};\ \lambda^{147}\text{Sm} = 6.54 \times 10^{+12}\ \text{yr}^{-1}$$

both granulites and amphibolites. Previous major and trace element analyses of the Lewisian indicate an igneous origin from a plutonic suite with calc-alkaline affinities[14,30,35–37]. Analytical procedures for the chemical separation and subsequent mass-spectrometric analysis of Sm and Nd have been described elsewhere[17,38]. The Sm/Nd ratios are mostly less than the bulk earth value (0.31) (refs 17–19, 39, 40), corresponding to light rare-earth enriched patterns; however, two basic granulites are slightly light rare-earth depleted and have Sm/Nd ratios up to 0.372.

The data are plotted on a Sm–Nd evolution diagram in Fig. 1. The best fit line[41] has a slope corresponding to an age of $2{,}920 \pm 50\ (2\sigma)$ Myr ($\lambda^{147} = 6.54 \times 10^{-12}\ \text{yr}^{-1}$) and an initial $^{143}\text{Nd}/^{144}\text{Nd}$ ratio of $0.508959 \pm 49\ (2\sigma)$. All the gneiss samples, irrespective of locality or metamorphic grade, conform closely to the best-fit line indicating that their igneous parent materials were derived contemporaneously and from source materials of similar history.

The Sm–Nd age obtained is significantly older than reliable ages obtained by whole-rock Rb–Sr and Pb–Pb and zircon U–Pb methods (see Table 1). The Pb–Pb and Rb–Sr data on whole rocks are consistent with a short time interval between formation of the igneous precursors and their chemical differentiation. The Sm–Nd age demonstrates that this is close to 200 Myr and the age is thus interpreted as the time of mantle–crust differentiation to produce the calc-alkaline precursors to the Lewisian. Specifically the time interval between the Pb–Pb and Sm–Nd whole-rock ages, $\Delta T_{\text{Nd-Pb}}$, is equal to 240 ± 90 Myr (uncertainties in the decay constants used should not significantly change this value).

Present day oceanic basalts exhibit a wide range of Nd compositions[38–40,42–45] with $^{143}\text{Nd}/^{144}\text{Nd}$ ratios between 0.51251 and 0.51329. This variation implies the existence of long lived mantle heterogeneities in Sm–Nd and an overall light rare-earth depletion (Sm/Nd > chondritic[46]) of oceanic upper mantle. The volume of mantle differentiated to produce the continental crust, the rate of crustal growth and the magnitude of the concomitant preferential light rare-earth (Sm/Nd < chondritic) enrichment into the crust are critical aspects of the history of present-day mantle heterogeneity. The precise timing of crust–mantle differentiation events and the evolution of radiogenic isotopes before such events would provide powerful constraints on solutions to these problems. We have shown that mantle–crust differentiation may be precisely dated by the Sm–Nd method. Furthermore, inferences concerning the previous Sm–Nd environment may be made from the corresponding initial $^{143}\text{Nd}/^{144}\text{Nd}$ ratios.

From Sm/Nd and $^{143}\text{Nd}/^{144}\text{Nd}$ ratios determined on Archaean single whole-rocks of known age, DePaolo and Wasserburg[39,40] suggested that Archaean continental crust had grown by differentiation of mantle sources that had previously evolved with an approximately chondritic Sm/Nd ratio. On an age against initial $^{143}\text{Nd}/^{144}\text{Nd}$ ratio plot (Fig. 2) their data plot close to a model growth line defined by the chondritic Sm/Nd ratio of 0.31 (ref. 46) and a $^{143}\text{Nd}/^{144}\text{Nd}$ ratio (0.50682) (ref. 47) equal to that in the Angra dos Reis achondrite at 4,550 Myr ago. Their contention has been strongly supported by the Sm–Nd whole-rock isochron studies of Hamilton *et al.*[17–19] on Archaean igneous rock suites. The ages and initial $^{143}\text{Nd}/^{144}\text{Nd}$ ratios obtained by the latter also plot close to the chondritic growth

line (Fig. 2), with Sm/Nd ratios computed for the time intervals from mantle–crust separations to 4,550 Myr being within error of 0.31. The time integrated Sm/Nd ratio for the igneous precursors to the Lewisian is 0.311 ± 4.

Several studies[48–50], including the present one, indicate that crustal metamorphism does not result in significant fractionation of Sm and Nd or perturbation of Sm–Nd isotope systematics. The major fractionation of Sm and Nd during Earth evolution is thus through the initial differentiation of the crust from the mantle. Using this fact and assuming differentiation of Archaean crustal segments from a chondritic Sm–Nd mantle environment, McCulloch and Wasserburg[50] computed model Sm–Nd ages from Sm/Nd and ^{143}Nd/^{144}Nd ratios measured on composite Canadian Shield samples. The model ages of 2,700–2,500 Myr agree with the available geological ages and give evidence of the derivation, within a short time interval, of a major crustal segment from essentially chondritic Sm–Nd reservoirs.

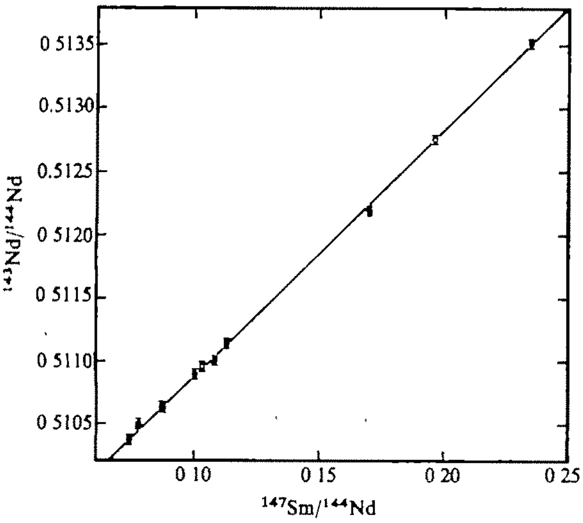

Fig. 1 Sm–Nd evolution diagram for the Lewisian gneisses. Age = $2,920 \pm 50$ Myr, initial ^{143}Nd/^{144}Nd ratio = 0.508959 ± 49.

Differentiation of continental crust and granulite formation

Whole-rock Pb–Pb data[4,10,11] for Lewisian granulites indicate that depletion of U (and by inference of Th) and alkali elements (K, Rb, Cs), continued to 2,700 Myr some 200 Myr after separation of the parent material from the mantle. The low concentrations of K, Rb, Cs, Th and U in Lewisian granulites (and possibly many other Precambrian granulites[51]) are not primary features of their igneous precursors, but are the result of metamorphic purging of these elements from the lower crust during a time interval of ~200 Myr. The characteristic depletion of alkali elements in granulites results in low Rb/Sr ratios, often lower than the bulk earth value (0.03) (refs 32, 33). This is particularly true for the Lewisian samples which have Rb/Sr ratios averaging about 0.02 (ref. 14). In contrast, amphibolite facies components of the Lewisian have Rb/Sr ratios higher than the bulk earth value. For example, the amphibolite facies gneisses studied by Moorbath *et al.*[4] have an average Rb/Sr of 0.4. The initial ^{87}Sr/^{86}Sr ratio of 0.7014 at 2,670 Myr obtained for these samples requires a time-integrated Rb/Sr ratio in the interval 2,920–2,670 Myr which is about an order of magnitude lower at ~0.03 but is still higher than that for the granulitic gneisses. Thus the amphibolitic gneisses may have acquired their high Rb/Sr ratios as a result of metamorphism and crustal differentiation. It seems feasible that some of the alkali elements lost from the granulite facies rocks during metamorphism migrated to higher structural levels.

Comparative rare-earth element (REE) abundance studies of granulite and amphibolite facies rocks[48,49] indicate that REE are not substantially fractionated by even high grade metamorphism and the data included here are in accord with these observations (see Table 2). Furthermore, the strong light REE enrichment seen in Lewisian granulites of acid to intermediate composition is compatible with their calc-alkaline nature and is not readily reconcilable with the theory that the heat producing and some other lithophile trace elements were removed in a partial melt as suggested by Fyfe[52]. Not only would such a mechanism tend to leave a residue with less fractionated rare-earth patterns than observed for most Lewisian granulite facies gneisses, but it would also tend to eradicate the isotopic evidence for earlier events. Crustal differentiation through upwards migrating non-magmatic fluids as proposed in more specific ways by Heier[6] and by Tarney and others[53] is supported by this study. On the other hand, the gross extension of such models to remove heavy rare earth and other elements from the Archaean lower crust by hydrothermal fluid transport, as recently proposed by Collerson and Fryer[54], is not supported by the Nd isotope data.

Is the time interval, $\Delta T_{\text{Nd–Pb}} = 240 \pm 90$ Myr, (during which crustal differentiation and stabilisation of granulites occurred), compatible with simple thermal considerations? To determine this we have assumed that within the interval $\Delta T_{\text{Nd–Pb}}$ the Lewisian crust can be modelled as a semi-infinite solid, containing 1 wt %K, (a conservative estimate), and $\text{K/U} = 10^4$ and $\text{Th/U} = 4$ by weight. Phase equilibrium considerations[31–33] indicate that at the end of this time interval the granulites were at a depth of at least 35 km, corresponding to a pressure of $\sim 10^4\ \text{N m}^{-2}$ (1GPa) and a temperature of ~1,100 K. If the temperature distribution in the Lewisian 2,920 Myr ago is conservatively estimated as increasing linearly with depth to 570 K at 35 km and it is further assumed that the heat input from the mantle is zero, then the subsequent temperature distribution as a function of time can be readily computed[55]. For values of the conductivity and thermal diffusivity of $3.3\ \text{W m}^{-1}\ \text{K}^{-1}$ and $1.6 \times 10^{-6}\ \text{m}^2\ \text{s}^{-1}$, respectively[56], it is found that the temperature at 35 km depth increases to 1,150 K after 50 Myr (2,870 Myr ago) and to 1,570 K after 100 Myr (2,820 Myr ago). This result indicates that extensive melting of the lower crust, even under anhydrous conditions, would occur by 2,820 Myr, unless the heat-producing elements migrated to higher structural levels

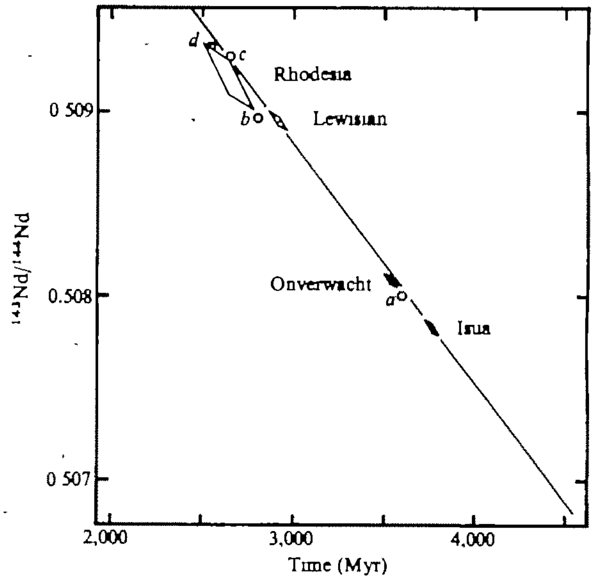

Fig. 2 Initial ^{143}Nd/^{144}Nd ratios of Archaean rocks plotted against age determined from whole-rock isochron data. Line represents growth of ^{143}Nd/^{144}Nd in a chondritic reservoir which had a ^{143}Nd/^{144}Nd ratio of 0.50682 at 4,550 Myr ago Data from DePaolo and Wasserburg[39,40], Hamilton *et al.*[17–19] and this paper. *a*, Amitsoq gneiss, Western Greenland; *b*, Preissac–Lacorne granodiorite, Superior Province, Canada; *c*, Fiskenaesset anorthosite, Western Greenland, *d*, Great Dyke, Rhodesia.

before this time. This conclusion holds for reasonable values of conductivity and thermal diffusivity and it should be emphasised that our estimates of K content and initial temperature distribution are conservative and that the mantle heat input was equated to zero. From these simple thermal considerations we may conclude that to avoid extensive melting, heat producing elements must have commenced migration from the lower crust <100 Myr after crustal thickening. The mechanism of this migration is still not clear but did not involve a transport medium which would significantly affect the Sm–Nd systematics, as would a magmatic phase.

The combined application of Sm–Nd, U–Pb and Rb–Sr systematics to ancient crustal terrains can provide important constraints on the early phases of crustal differentiation and stabilisation. This is a simple reflection of the markedly different mobilities of these elements during crustal differentiation processes. At least in the case of the Lewisian crust, the completion of metamorphic differentiation and granulite formation succeeded the primary igneous differentiation of parent materials from the mantle by 240 ± 90 Myr. The heat producing elements were transported to higher crustal levels from where heat could be readily dissipated, and the granulite facies lower crust was maintained in a more refractory and thermally stable condition.

This research was supported by grant EAR-75-20891 from the NSF. We thank G. Wesselmann for technical assistance.

Pc 1 Duarte, a common polymorphism of a human brain protein, and its relationship to depressive disease and multiple sclerosis

David E. Comings

Department of Medical Genetics, City of Hope National Medical Center, Duarte, California 91010

Pc 1 Duarte, a common variant of a human brain-specific protein, is present in one-third of the control population and has a gene frequency of 0.17. There was a significantly increased frequency of mutant heterozygotes and homozygotes among individuals with depressive disease. This is consistent with a model in which Pc 1 *Duarte is the major gene in depressive disease, acting in conjunction with an environmental threshold effect.*

THE genetic basis of the major psychoses is poorly understood. In schizophrenia, twin, family and adoption studies clearly indicate the importance of genetic factors[1–3]. The affective psychoses have been less extensively studied, but again family and twin studies provide strong evidence of genetic factors[3–5]. Proposed mechanisms for these psychoses include a single autosomal dominant gene with reduced penetrance[6–10], a single recessive gene[11], a predominantly recessive gene with an environmental threshold effect[12], polygenic inheritance[5,13–15] and in the case of manic-depressive psychosis, X-linked inheritance[16].

Several years ago I began a search for the mutant protein in Huntington disease using two-dimensional gel electrophoresis of many different extracts of brain and other tissues. Although the mutant protein in this disorder has not yet been found, a perchloric acid (PCA) extract of the caudate and putamen showed a commonly occurring mutant protein, which I call Pc 1 Duarte (ref. 17). By electrophoretic studies, it is absent from non-neural tissues and thus represents the first polymorphism of a human protein specific to nerve tissue. Because this protein is prominent in the caudate and putamen, the major site of dopaminergic neurones believed to be involved in schizophrenia[18,19], and because some genetic theories suggest a primarily

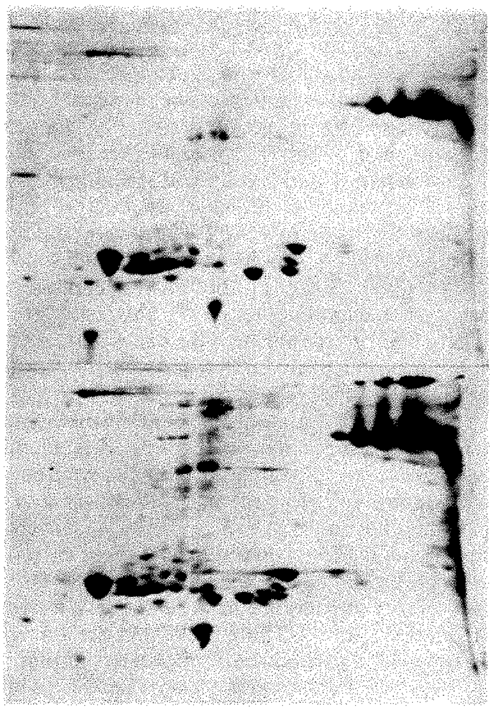

Fig. 1 Two-dimensional gel electrophoresis of PCA extracts of the caudate and putamen of homozygous normal (*Pc 1 A*/*Pc 1 A*) (top) and heterozygous (*Pc 1* Duarte/ *Pc 1 A*) (bottom) individuals. Frozen brain material was allowed to thaw and each gramme of tissue mixed with 3 ml of 0.13 M PCA plus 0.03 ml of phenylmethylsulphonyl fluoride (16 mg per ml ethanol). This was homogenised in a Teckmar homogeniser (Cincinnati) for 30–60 s. The homogenate was placed on a rocker at 4°C for 1 h then centrifuged 10,000 *g* for 20 min. The supernatant was dialysed against 0.05% β-mercaptoethanol for 4 changes then lyophilised. Electrophoresis was by the technique of O'Farrell[44] with the following modifications. Isofocusing was done in 3.7-mm i.d. Pyrex tubes with 12-cm long 5% acrylamide gel made from a stock solution of 25.5% acrylamide, 4.5% *N'N'*-diallyltartardiamide. The final gel contained 9.5 M urea, 2% NP40 and 2% BioRad ampholytes (2 parts 3–10, 6 parts 4–6, 4 parts 5–7, 1 part 7–9). The anode solution was 0.01 M phosphoric acid, the cathode solution 0.04 M NaOH, 0.02 M $Ca(OH)_2$. The gels were electrophoresed at 500 V overnight. The *p*H gradient was read directly on the gel with a flat bed electrode. The second dimension was a 12.5% acrylamide–sodium bicarbonate gel as described by O'Farrell[44]. After electrophoresis the gels were stained overnight in 0.05% Coomassie brilliant blue R dissolved in 10% acetic acid–25% isopropanol, destained for 2 h in 10% acetic acid–25% isopropanol, and destained an additional 24 h in 10% acetic acid. The gels were photographed with contrast process Ortho Kodak film with a yellow filter. To determine the molecular weight of Pc 1 Duarte, standards were included with sample in one gel and this compared with a gel without standards and with a gel of standards alone.

recessive but common mutant gene, it was of interest to determine if *Pc 1* Duarte was associated with any of the major psychoses. Significant correlations were found with the depressive diseases and with multiple sclerosis.

Electrophoresis

Two-dimensional gel electrophoresis of the PCA extract of the caudate and putamen of a normal *Pc 1 A*/*Pc 1A* (*AA*) individual and a *Pc 1* Duarte/*Pc 1 A* (*AD*) heterozygote is shown in Fig. 1. The critical portion of the gel in these two individuals plus a *Pc 1* Duarte homozygote (*DD*) are shown in Fig. 2 and the terminology is illustrated in Fig. 3. In the normal homozygote there is a major polypeptide, Pc 1 AI, and two minor satellite polypeptides, Pc 1 AII and AIII. In the variant the major polypeptide is exactly split to form an additional, more basic protein, Pc 1 Duarte I. The two minor satellite polypeptides are also split to form Pc 1 Duarte II and III. Faint polypeptides Ia and IIa migrate just ahead of both the normal and variant I and II. The splitting of three polypeptides into six in the presence of the variant indicates that AI, II and III all have the same polypeptide sequence and the separation into three forms is due to post-transcriptional modifications.

A single amino acid substitution leading to more basic mutant polypeptides explains the observed pattern. There was no correlation between this mutant pattern and drug intake, age, time from death to autopsy, or source of the brains. The patterns are highly reproducible. Many samples have been run two to three times, some seven times, with the same result.

There were approximately 20 major and 40 minor polypeptides in the PCA extracts. None of the other polypeptides were polymorphic. The Pc 1 terminology (*Perc*hloric acid extract) allows naming of Pc 2, Pc 3 and so on, as other polypeptides are studied. The protein was not present in PCA extracts of fibroblasts, liver, kidney, spleen or lung and thus seems to be nerve tissue specific.

To examine the intracellular distribution of Pc 1 A, PCA extracts of various brain fractions were electrophoresed. Pc 1 A was present only in the 100,000*g* supernatant fraction, indicating it to be a cytosol protein and not intimately attached to the nucleus, myelin, synaptosomes, mitochondria or cell membranes.

To examine the distribution of this protein, PCA extracts of many parts of the brain were electrophoresed. Pc 1 A was most prominent in the caudate and putamen, thalamus, medulla, pons and brain stem. It was present in lower relative amounts in the temporal, parietal and occipital lobe and cerebellum. The portion of the brain with the lowest relative amount was the frontal cortex. It was present in brains of stillborn infants, indicating that it was not a developmentally late protein. There was no significant difference in the amount of Pc 1 A in grey compared with white matter. Its molecular weight is 19,300 by SDS-gel electrophoresis. Its isoelectric point in 9 M urea is 5.7, comparable to 4.2–4.7 in the absence of urea.

Relation of Pc 1 Duarte to neurological disease

To determine if this mutation was related to any specific neurological disease, brains from 276 individuals who had died of various disorders were examined (Table 1). In 103 controls dying of cancer, heart disease, accident and other non-neurological disorders, there were 28 heterozygotes and 4 homozygotes from a total of 32 carrying the *Pc 1* Duarte mutant. In 49

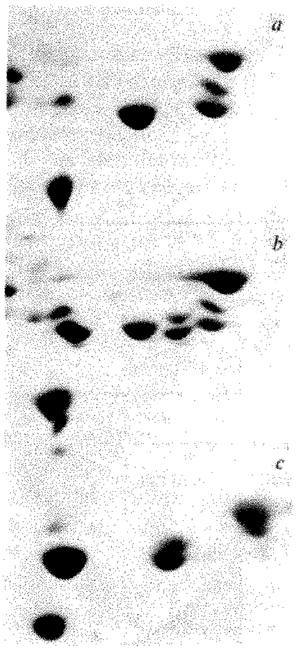

Fig. 2 Critical area of the gel *Pc 1 A*/*Pc 1 A* homozygous (*a*), *Pc 1* Duarte/*Pc 1 A* heterozygote (*b*) and *Pc 1* Duarte, *Pc 1* Duarte homozygous (*c*) individuals. In the heterozygote three polypeptides are split into six.

Table 1 *Pc 1* Duarte in various neurological disorders

Diagnosis	n	D/A	%	D/D	%	Total % carrying mutation

No % given with n less than 10. MS, multiple sclerosis; SSPE, subacute sclerosing panencephalitis, AMLS, amyotrophic lateral sclerosis.

individuals with Huntington disease there were 16 heterozygotes and no homozygotes. As this is a single gene disorder and *Pc 1* is obviously not the affected gene, the Huntington disease patients can be added to the other controls to give a total of 152 individuals, with 48, or 31.6%, carrying the mutant gene. In these control individuals the gene frequency for the *Pc 1 A* allele, p, is $2\times AA+AD/2N$ or 0.83, and the frequency of the *Pc 1* Duarte allele, q, is 0.17. The expected DD frequency, q^2, is 0.029, which was not significantly different from the observed frequency of 0.026.

A surprising association was found with multiple sclerosis. Of 40 individuals examined, 21, or 52.5%, were heterozygotes. Comparison with the above controls by the Chi square test gives an χ^2 of 6.0 and $P<0.025$. Combination of multiple sclerosis with subacute sclerosing panencephalitis and amyotrophic lateral sclerosis, all apparently associated with viral infections[20–24], gave a total of 27 heterozygotes (55.1%) in 49 cases. Here the χ^2 was 8.77 and $P<0.005$. The relative risk[25] to *Pc 1* Duarte carriers of developing multiple sclerosis is 2.4.

The mean age of the multiple sclerosis AD heterozygotes was 50.1 ($n=20$, s.d. $=13.3$), whereas the mean age of the multiple sclerosis AA homozygotes was 47.9 ($n=18$, s.e.m. $=14.2$). These are not significantly different. Thus, it cannot be said that the presence of the *Pc 1* Duarte mutation leads to earlier, more severe disease. The frequency among 30 definite and probable schizophrenics was similar to that in controls.

Table 2 χ^2 and P values

	χ^2	P
For total % carrying the *Pc 1* Duarte mutation		
Virus-associated diseases		
Controls versus MS	6 02	<0.025
Controls versus MS + SSPE + AML	8 77	<0 005
Depressive disease		
Controls versus St Louis series	10 89	<0.001

Controls versus total depressive disease	14 84	<0 0005
For % DD homozygotes		
Depressive disease		
Controls versus St Louis series	11 54	0.001
Controls versus total depressive disease	6 40	0.01

Because of some preliminary observations suggesting a high frequency of *Pc 1* Duarte in manic-depressive psychoses, alcoholism and suicide, an effort was made to obtain more brain samples from individuals with depressive diseases. I obtained 28 brain samples, part of a collection made over the years from individuals who had committed suicide. Medical and family records were examined and the individuals classified into suicide–alcoholic or suicide–depressive, depending on a set of criteria outlined by Feighner *et al.*[26]. Those who did not fit this classification or for whom insufficient information was available were not examined. Some of the suicide depressives were further classified as manic-depressive[26]. The results are given in Table 1. There were no significant differences between the three groups, but in the total group of 28 there were 13 AD heterozygotes and 5 DD homozygotes. Thus, in this group, 64.2% carried the *Pc 1* Duarte mutation and 17.9% were homozygous. As shown in Table 2, these figures are all significant, and for DD homozygotes in controls compared with the St Louis brains, $P=0.001$. Among suicides, manic depressives and chronic alcoholics from other sources, 9 of 14, or 64%, carried the *Pc 1* Duarte mutation. Of 42 total individuals in these groups, 52.4% were heterozygous AD and 11.9% homozygous DD for a total of 64.3% carrying the mutation. These are all significantly different from the controls (Table 2). Within the manic-depressive group only, 73% carried the *Pc 1* Duarte mutation. Based on the St Louis series, the relative risk of a DD homozygote developing depressive disease was 8.0; for the St Louis plus other series it was 5.0.

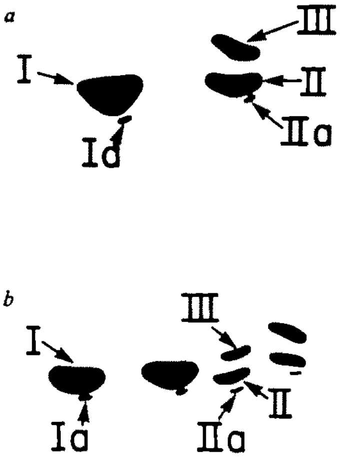

Fig. 3 Nomenclature for the Pc 1 A (*a*) and Pc 1 Duarte (*b*) polypeptides.

As the mean age of the non-Huntington disease controls was 52.6 (s.d. 18.5) and the mean age of the AD and DD individuals with depressive disease was 46.5 (s.d. 16.1), any age correction for the late onset of depressive disease would not increase the frequency of depressives among the mutant individuals.

The data on sex and race for those on whom such information was available are shown in Table 3. As this includes all cases, the total frequency for *Pc 1* Duarte is higher than that in the control group alone. The equal occurrence in males and females indicates that the gene is on an autosome. The equal occurrence in caucasians and blacks indicates that the gene has a widespread distribution and makes it unlikely that the increased frequency in depressive disease and multiple sclerosis is simply due to the presence of a subset of the population having both a high frequency of this gene and increased predisposition to these two disorders.

The genetics of depressive disease

There is a striking similarity between the results obtained here and the model of the genetics of schizophrenia proposed by Kidd

Table 3 Occurrence of *Pc 1* Duarte according to sex and race

	AA	*AD*	*DD*	Total	%*AD* +*DD*
Males	92	55 (36.4%)	4 (2.6%)	151	39.0
Females	55	37 (39.5%)	4 (4.1%)	96	42.6
Total	147	92	8	247	
Caucasians	93	59 (38.1%)	3 (1.9%)	155	40.0
Blacks	12	9 (40.9%)	1 (4.5%)	22	45.4
Total	105	68	4	177	

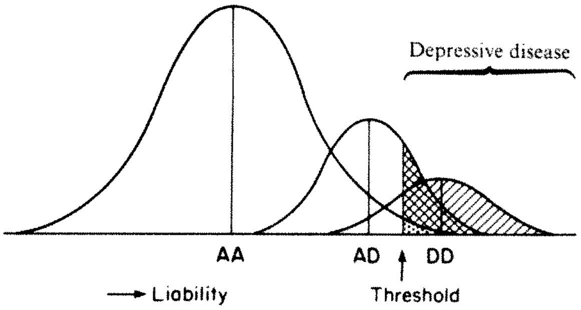
and Cavalli-Sforza[12]. Although their model was for schizophrenia, the genetic aspects of the depressive disorders are similar. In both, studies of twins show concordance rates for monozygotic twins of 30–93% and for dizygotic twins of 0–24% (refs 3–5). The significantly greater concordance rate for monozygotic compared with dizygotic twins indicates that genetic factors play an important part, and the concordance rates of less than 100% for monozygotic twins indicates that environmental factors are also important. Both have a relatively high frequency in the general population, 0.3–2.9% for schizophrenia[3] and 0.6–3.3% for depressive disease[4,27,28]. Both show a frequency in first-degree relatives of 5–39% (refs 3,4,29), significantly greater than in the general population but less than expected on the basis of a fully penetrant dominant gene.

The basic element of the Kidd–Cavalli-Sforza hypothesis is that a single, primarily recessive gene is involved in combination with a threshold effect due to environmental factors, and the gene frequency is high. I have modified their Fig. 2 to represent *AD* heterozygotes and *DD* homozygotes (Fig. 4). According to this model, *Pc 1* Duarte is the single major gene involved in depressive disease; most *AA* individuals are unaffected but some may be; *AD* individuals are at greater risk but the majority are unaffected; *DD* individuals are at greatest risk, but even here some are unaffected. The observed gene frequency is high, 0.17.

In the depressive diseases the gene would be less recessive than in the application of the model to schizophrenia. This conforms with the results of Mendlewicz and Rainer[29] in their application of the Kidd–Cavalli-Sforza hypothesis to manic-depressive disease. Depressive disease seems to be at least a partially heterogeneous disorder. The most common distinction is between monopolar (pure depressive) and bipolar (manic depressive) disease, but even here the genetic overlap is considerable[4,30–33].

Heterogeneity on the basis of response to drugs has also been suggested[34,35]. Although the incidence of *AD* and *DD* individuals may be even greater in certain types of depressive disease, the subtypes of suicide–depressive, suicide–manic depressive and suicide–alcoholic were similar (Table 1). Of the 11 manic depressives, 9 were male; the two females were *AD*. The preliminary evidence suggesting a relationship between *Pc 1* Duarte and chronic alcoholism could explain some of the genetic aspects of this disorder[36,37] and its association with affective illness[38].

Fig. 4 Application of the Kidd–Cavalli-Sforza hypothesis[12] to the present data suggesting that *Pc 1* Duarte is the single major gene involved in depressive disease and acts in conjunction with an environmental threshold effect. See text. ⊡, *AA* individuals; ▩, *AD* individuals; ▨, *DD* individuals.



Multiple sclerosis

The significant association of *Pc 1* Duarte with multiple sclerosis and with other similar diseases such as subacute sclerosing panencephalitis and amyotrophic lateral sclerosis was intriguing. These diseases are either clearly associated with viruses, as in the case of subacute sclerosing panencephalitis[21–23], or suspected of being so associated[20,24]. Studies of *HLA* genes[39–42] show an association of *HLA-A1* and *3, B7, Cw2* and *Dw2* with multiple sclerosis, the latter being the most significant. These data have suggested the presence of a multiple sclerosis susceptibility gene (*MSSG*) which is either the same as the *Dw2* gene or linked to it. Figure 5 shows the possible relationship between the *HLA* loci, *MSSG* and *Pc 1* Duarte. *Pc 1* Duarte may be linked to the *HLA* locus but separate from the *MSSG*, which is either identical to *Dw2* or linked to it (*a* and *b*). *Pc 1* Duarte itself may be the *MSSG* (*c*), or it may be unlinked to the *HLA* locus and only fortuitously associated with multiple sclerosis (*d*). Possibility *c* suggests that the presence of *Pc 1 A* Duarte may alter the host response to central nervous system viral infection. Possibilities *a* and *b* suggest that the high frequency of *Pc 1* Duarte in the population may have been due to the fortuitous occurrence of this mutation on an *HLA* haplotype that for other reasons has been selected for. This could explain the persistence of a genetically disadvantageous disease associated with a mental disorder, at a relatively high level in the population.

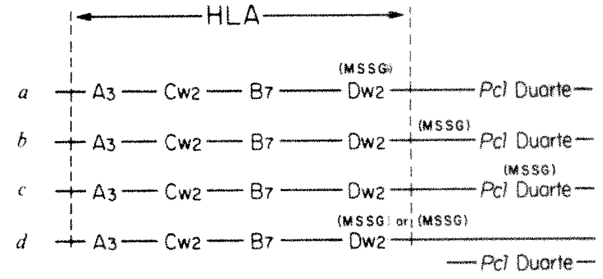


Fig. 5 Possibilities for the linkage relationship between *Pc 1* Duarte, the *HLA* locus and the multiple sclerosis susceptibility gene (*MSSG*). The *MSSG* mutation may have occurred on a chromosome carrying the *HLA A-3, Cw2, B7, Dw2* haplotype. However, these associations with multiple sclerosis do not necessarily imply that these genes are all on the same chromosome.

If the *Pc 1* Duarte mutation is the major single gene in depressive disease and is associated with multiple sclerosis, one might expect to see an association between depressive disease and multiple sclerosis. I am unaware of such an association, although Shapiro *et al.*[43] report that a significantly higher percentage of patients with a family history of affective disorders had *HLA-B7* (55%) compared to those without such a family history (19%) ($P = 0.001$). This is consistent with possibilities *a*, *b* and *c* in Fig. 5.

These studies suggest that a similar polymorphic gene interacting with environmental thresholds would account for most schizophrenia. We have examined many different subfractions of the caudate, putamen and neocortex of schizophrenics and have not yet found a comparable mutation.

The most difficult aspect of these studies is obtaining brain specimens. I would be pleased to receive frozen specimens from well documented cases of individuals dying of any behavioural or hereditary neurological disorder, especially schizophrenia, depressive disease, chronic alcoholism, hyperactivity syndrome in children, autism, tuberous sclerosis and the hereditary ataxias. These would be examined both for Pc 1 Duarte and for other mutant proteins.

I thank Evangelita Avelino, Anu Jalanko, Lale LeFever, Doug McCullough, Michael Oase and Jeff Silverman for technical assistance, and the individuals listed under Table 1, and Sylvia Moses, Dr Wallace W. Tourtellotte, Edward Bird, Richard Davis, Eli Robbins, and the City of Hope Medical Center for the donation of brain specimens. This work was supported by NIH grant GM-15886 and the H.D. Foundation.

Mechanism of β-adrenergic relaxation of smooth muscle

C. R. Scheid, T. W. Honeyman & F. S. Fay

Department of Physiology, University of Massachusetts Medical School, Worcester, Massachusetts 01605

The mechanism of β-adrenergic relaxation was investigated in isolated smooth muscle cells. β-adrenergic agents stimulate cyclic AMP-dependent phosphorylation, enhance Na^+/K^+ transport and induce relaxation. The stimulation of Na^+/K^+ transport is obligatory for relaxation, and we suggest that this stimulation induces relaxation through enhanced Na^+/Ca^{2+} exchange.

IT has long been recognised that catecholamines cause relaxation of visceral smooth muscle[1,2]. Despite intensive studies, the biochemical and physiological events that translate this hormone signal into a change in smooth muscle tone are unknown. In other tissues, however, the events responsible for catecholamine actions are better understood. Since Sutherland and Rall suggested that cyclic AMP may serve as the intracellular mediator of the effects of glucagon and adrenaline[3,4], considerable evidence has accumulated indicating that many catecholamine actions, notably those mediated by β-adrenergic receptors[4], are mediated by protein phosphorylations catalysed by protein kinases. These protein phosphorylations are a consequence of an increase in cyclic AMP brought about by β-adrenergic stimulation of adenylate cyclase. The rise in cyclic AMP activates cyclic AMP-dependent protein kinase, which by phosphorylation of specific proteins, alters cellular functions such as glycogenolysis, lipolysis and ion transport[5–7].

An analogous sequence of protein phosphorylations has been suggested to mediate β-adrenergic-induced relaxation of smooth muscle[8,9]. As most evidence suggests that this relaxation results from a decrease in Ca^{2+} availability[10,11], it has been further suggested that the protein phosphorylated by this mechanism either directly or indirectly controls Ca^{2+} distribution[9,12]. Although this hypothesis is plausible, consideration of the literature reveals that evidence for such a cascade in β-adrenergic-induced relaxation is equivocal for several reasons[13–15]. First, an increase in cyclic AMP does not always correlate with the relaxation induced by isoprenaline. In addition, drug-induced changes in cyclic AMP-dependent protein kinase have yet to be measured. Finally, uncertainty persists regarding the manner in which β-adrenergic agents affect Ca^{2+} distribution. Studies of isoprenaline action suggest effects on the distribution of Na^+ and K^+ (refs 16–19) as well as of Ca^{2+} (refs 11, 17–23). Thus, it is not known if the effects of isoprenaline on Ca^{2+} distribution are direct or a secondary consequence of the redistribution of other ions.

The contradictions and uncertainties concerning the mechanism of β-adrenergic-induced relaxation of smooth muscle can largely be attributed to problems in interpretation of studies on intact tissue. The heterogeneity of cell types, the electrical and mechanical coupling between individual smooth muscle cells, and the complex extracellular diffusion paths have all imposed serious limitations on such studies. The availability of a preparation of enzymatically disaggregated smooth muscle cells from the stomach muscle of *Bufo marinus* permits a more direct examination of the mechanism of β-adrenergic-induced relaxation. Previous studies have revealed that these smooth muscle cells retain many of their mechanical, ultrastructural, biochemical, pharmacological and electrical properties following isolation[24–31]. Of particular importance to the present studies was the finding that isoprenaline caused a decrease in the responsiveness to contractile agents[26]. Because isoprenaline also increases cyclic AMP levels[26], we examined the possible links between these two effects of β-adrenergic stimulation. Specifically, we examined whether the link involves cyclic AMP-dependent protein phosphorylation and consequent stimulation of the Na^+/K^+ pump. In addition, we have examined how changes in the Na^+/K^+ pump are linked to changes in contractility.

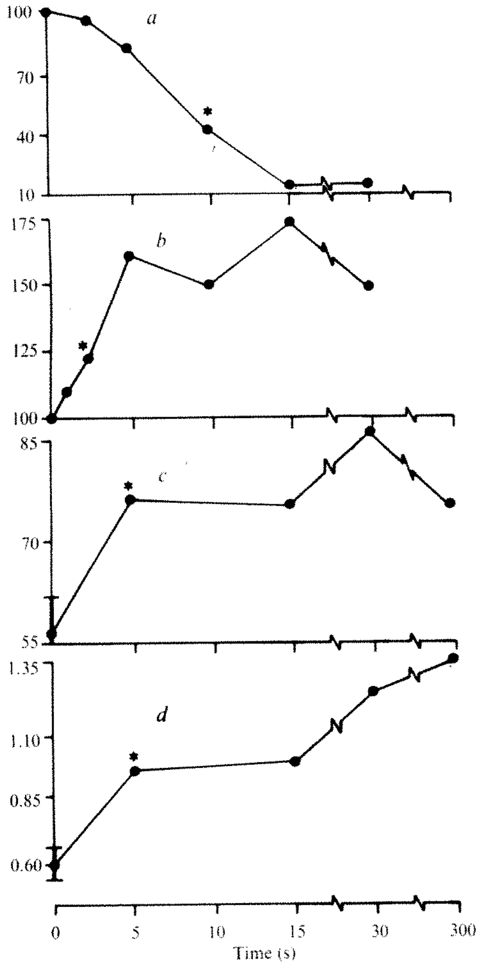

Fig. 1 Time course for the effects of isoprenaline on contractility, cyclic AMP, cyclic AMP-dependent protein kinase and phosphorylase *a* in suspensions of isolated smooth muscle cells. All experiments were carried out at 10^{-5} M isoprenaline. Cells were prepared and suspended as described previously[47]. The asterisk in all panels indicates when the response was significantly different from the control. Statistical significance for each of these four parameters was assessed from data pooled from the following experiments: *a*, % contraction, 12 experiments; *b*, cyclic AMP, 5 experiments; *c*, protein kinase, 4 experiments; *d*, phosphorylase, 4 experiments. *a*, Isoprenaline significantly decreased contractility within 10 s. Changes in the contractile state of a population of cells were assessed by comparing pulse height distributions as drug-treated and untreated aliquots of a single cell suspension were passed through a Coulter counter[47]. This method of analysing contractile changes is based on the finding that pulse amplitude is a measure of cross-sectional area that increases as the cells actively shorten. As the cells in suspension are already relaxed, the addition of inhibitory agents does not result in a shift in pulse height histograms. Therefore, we determined the changes in potential for contraction by first incubating the cells with isoprenaline and then challenging them with a brief (6 s) exposure to the excitatory agent, carbachol (5.5 μM). The effect of isoprenaline was evident as a progressive decrease in the contractile response to carbachol with longer isoprenaline exposures. It was expressed as a percentage of the contractile response observed in the presence of carbachol alone. As the effect of isoprenaline on all parameters other than contractility was determined without an excitatory agent, it is important to note that previous studies have shown that the time course for isoprenaline action on contractility is unaffected by the use of carbachol. This justifies comparison of the time course of the effects of isoprenaline on contractility determined in the presence of carbachol with the time course of effects on other parameters. *b*, Isoprenaline significantly increased cyclic AMP levels within 2.5 s. Cyclic AMP was determined by competitive protein binding assay[48] in cell extracts prepared by sonication in perchloric acid. Changes in cyclic AMP were expressed as a percentage of control cyclic AMP levels. *c*, Isoprenaline significantly increased the activity of cyclic AMP-dependent protein kinase within 5 s. Cell extracts were prepared by the addition of NaCl and EDTA to the cell suspension just before homogenisation with a Tekmar omnimixer. The ratio of protein kinase activities assayed in the absence and presence of 4 μM cyclic AMP was used as an index of the state of enzyme activation *in situ*[33]. These values are expressed as % active protein kinase. *d*, Isoprenaline significantly increased phosphorylase *a* activity within 5 s. Cell extracts were prepared by the addition of KF and EDTA to the suspension just before homogenisation with a Tekmar omnimixer and assayed as described by Hardman *et al.*[49]. Activity is expressed as nmol glucose-1-phosphate formed per min per mg protein.

Isoprenaline effects on contractility and cyclic AMP-dependent phosphorylation

A series of experiments was carried out to determine the involvement of cyclic AMP-dependent protein phosphorylation in the change in contractility induced by isoprenaline. The contractile responsiveness of the cells was monitored using the Coulter counter technique (see legend to Fig. 1 and ref. 27). As the cells in suspension were already fully extended, the relaxing effect of isoprenaline could only be assessed as inhibition of the response to an excitatory stimulus. As shown in Fig. 1, isoprenaline decreased the contractile response of isolated smooth muscle cells to excitatory agents in a time-dependent manner. It also increased cyclic AMP levels in the isolated cells (Fig. 1), and both the increase in cyclic AMP and the decrease in contractility exhibited identical dose dependencies[26]. Both effects are apparently mediated by β-adrenergic receptors, as both responses are fully blocked by propranolol (10^{-4} M). Although both responses occurred rapidly, the increase in cyclic AMP seems to occur more rapidly than the decrease in contractility. Thus, the data are consistent with the notion that relaxation is mediated by a cyclic AMP-dependent process. This is further supported by the finding that cyclic AMP mimicked the effect of isoprenaline on contractility when applied exogenously[26] or when applied intracellularly by microinjection[29].

To evaluate further the role of cyclic AMP and cyclic AMP-dependent protein phosphorylation in relaxation, we examined the effects of isoprenaline on cyclic AMP-dependent protein kinase. The toad smooth muscle contains a cyclic AMP-dependent protein kinase which, on the basis of its elution pattern from DEAE-Sephadex, is primarily the type II isozyme[32,33]. The activity of this enzyme was increased by exposure of the cells to isoprenaline (Fig. 1), with an average twofold maximal change. The increase in protein kinase activity seemed to occur more rapidly than the change in contractility. Thus, the data are consistent with the notion that relaxation is mediated by changes in the activity of cyclic AMP-dependent protein kinase.

To gain some insight into the rate at which cyclic AMP-dependent protein phosphorylation occurs in intact cells, we examined the effects of isoprenaline on phosphorylase activity. In many tissues, activation of cyclic AMP-dependent protein kinase leads to activation of phosphorylase by a sequence of protein phosphorylations involving phosphorylase *b* kinase as an intermediate. Isolated smooth muscle cells contain phosphorylase *b* kinase, as extracts catalysed the conversion of purified phosphorylase *b* to phosphorylase *a*. Exposure to isoprenaline caused a nearly twofold increase in phosphorylase *b* kinase activity (control: 0.047 ± 0.006; isoprenaline: 0.084 ± 0.0015 U phosphorylase *a* formed per min per mg protein; assayed as described by Bueding *et al.*[34]). Isoprenaline also increased phosphorylase *a* activity (Fig. 1) and dibutyryl cyclic AMP mimicked this effect. Like the activation of cyclic AMP-dependent protein kinase, activation of phosphorylase by isoprenaline occurred rapidly (significant increases were observed within 5 s). Thus, cyclic AMP-dependent protein phosphorylation can occur rapidly enough in the intact cell to mediate β-adrenergic-induced relaxation. It seemed unlikely, however, that the change in phosphorylase *per se* could account for relaxation[34]. Therefore, we investigated whether other cellular processes are altered by isoprenaline and if so, whether such alterations involve cyclic AMP-dependent protein phosphorylation.

Isoprenaline effects on Na^+ and K^+ fluxes

Several previous studies had suggested that β-adrenergic effects on smooth muscle might involve a redistribution of Na^+ and K^+ across the cell membrane[20-23]. Because of the difficulties imposed by intact tissue, these data are somewhat equivocal and inconclusive. Therefore, we investigated the effect of isoprenaline on unidirectional Na^+ and K^+ fluxes in the isolated

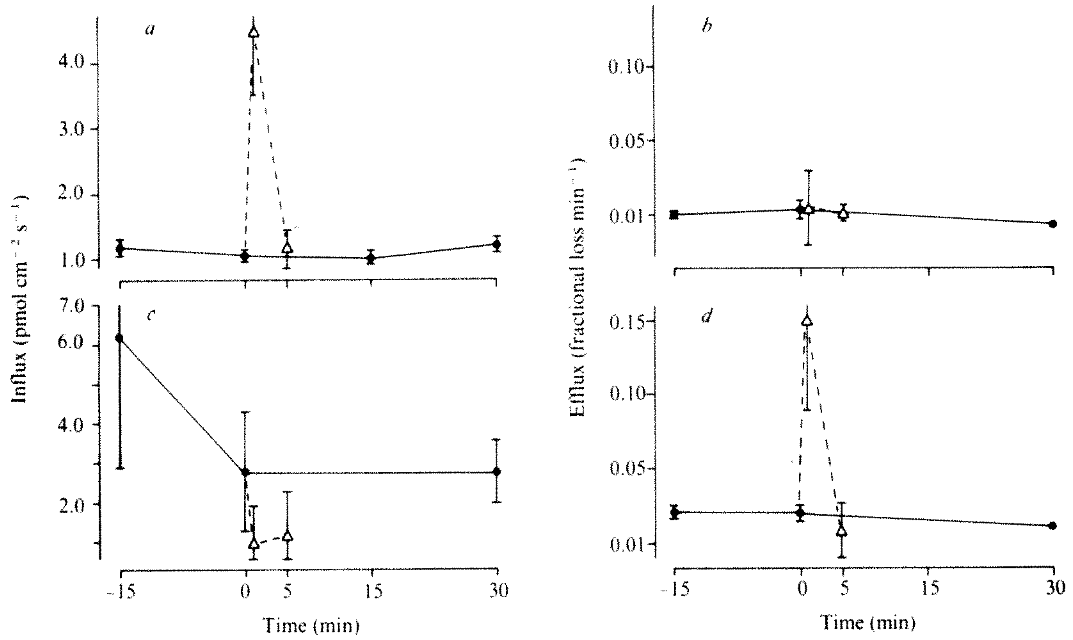

Fig. 2 Effects of isoprenaline on the influx and efflux of Na^+ and K^+ in isolated smooth muscle cells. For influx studies, cells in aliquots of a single suspension were centrifuged through silicone oil at various times after addition of radioactive ion. ^{14}C-urea and ^{3}H-inulin were included to determine the total water and extracellular water associated with the cell pellet, respectively. Cellular ion uptake (expressed as pmol cm^{-2} s^{-1}) after correction for extracellular radioactive ion, and backflux and decay of radioactive ion during counting, was calculated[50] using an average surface area/volume ratio of 5×10^3 cm^{-1} obtained by morphometric analysis of fixed cells. The same general procedure was used to study ion efflux. After several hours' exposure to radioactive ion, the specific activity of the bathing medium was reduced by dilution and the rate of loss of radioactivity from the intracellular compartment was monitored. The ion content of the cells was determined by flame photometry. An index of efflux rate was obtained by calculating[50] the fractional change in specific activity per min. In both influx and efflux experiments, isoprenaline (10^{-4} M) was added after the fluxes had achieved a stable rate, indicating exchange between a simple two-compartment system. The addition of isoprenaline was denoted time zero so that experiments could be compared. The cells did not seem to have been damaged by the experimental procedures, as the K^+ content was essentially identical to that in the intact tissue (cells: 131.5 ± 5.2 mmol per l intracellular water; tissues 138.1 ± 4.5 mmol per l intracellular water). Each point on the graph represents the mean ±s.e.m. calculated from the following experiments. ***a*, ^{42}K influx**. The addition of isoproterenol at time zero stimulated ^{42}K influx 3.4 fold (triangles) over control (circles). This effect was observed within 1 minute but was no longer evident at 5 min. ***b*, ^{42}K efflux**. The addition of isoproterenol (triangles) at time zero did not stimulate the efflux of ^{42}K above that of controls (circles). ***c*, ^{24}Na efflux**. The addition of isoproterenol (triangles) at time zero stimulated ^{24}Na efflux 7.6 fold over that of the control (circles). Like the effects of isoproterenol on ^{42}K influx, this effect was observed within 1 minute, but was no longer evident by 5 minutes. ***d*, ^{24}Na influx**. The addition of isoproterenol (triangles) at time zero did not stimulate ^{24}Na influx over control (circles). The influx values for the isoproterenol group represent an underestimate of the true values in that the backflux correction factors could not fully correct for the enhanced backflux (efflux) caused by isoproterenol.

cells. Exposure to this drug caused a large, rapid increase in ^{42}K influx and ^{24}Na efflux (Fig. 2). The stimulation was maximal at the earliest time which could be investigated (45 s) and was detectable at concentrations as low as 10^{-8} M. At concentrations of 10^{-6} M or greater, ^{42}K influx was increased by an average of 3.4 times above the control value of 1.2 ± 0.3 pmol cm^{-2} s^{-1}. ^{24}Na efflux was increased by 7.6 times above its control value of 2.9 ± 0.6 pmol cm^{-2} s^{-1}. By contrast, ^{42}K efflux and ^{24}Na influx were not significantly altered by isoprenaline. As the stimulation of ^{24}Na influx and ^{42}K efflux was no longer detectable by 5 min, large changes in ion content in response to isoprenaline are not to be expected. We calculate a net Na^+ efflux per cell in response to isoprenaline of 0.08 pmol; this represents a net decline in intracellular Na^+ of only 8%. The predicted change in K^+ content would be less than 1%. Given the analytical error associated with ion content determinations, it is not surprising that isoprenaline produced no significant change in either Na^+ (65.5 ± 4.4 mmol per l intracellular water) or K^+ (131.5 ± 5.2 mmol per l intracellular water) content. The observation that isoprenaline stimulated the movement of Na^+ and K^+ against their respective electrochemical gradients suggested that the Na^+/K^+ pump had been stimulated. To test this possibility, we examined the effects of ouabain on K^+ movement. Ouabain at 5×10^{-4} M completely abolished the stimulatory effect of isoproterenol on ^{42}K influx in three experiments; at this dose it reduced the control ^{42}K uptake by 50% (data not shown). These flux studies indicate thus that isoprenaline stimulates the Na^+/K^+ pump in the isolated smooth muscle cells. Two important questions arise from this conclusion. First, is the change in pump activity mediated by a cyclic AMP-dependent phosphorylation mechanism as has been proposed for relaxation? Second, does the change in pump activity lead to relaxation, and if so, how?

Table 1 Stimulation of Na^+/K^+-dependent ATPase activity by cyclic AMP-dependent protein kinase

	Na^+/K^+ ATPase activity (nmol per min per mg protein)
− Protein kinase	40 ± 17
+ Protein kinase	81 ± 28

Membrane fragments (50–200 μg) as described in the legend to Fig. 3 were preincubated with 10–50 μg of partially purified cyclic AMP-dependent protein kinase[51] (specific activity of 25 pmol histone phosphate formed per min per μg protein). As the protein kinase preparation had appreciable catalytic activity even in the absence of cyclic AMP, the nucleotide was not included. The reaction mixture was diluted and ATPase activity determined by the liberation of ^{32}Pi from [γ-^{32}P]ATP (ref. 52). The difference in ATPase activity assayed in the presence of K^+ alone and in the presence of $Na^+ + K^+$ was defined as Na^+/K^+ ATPase activity. Preincubation of fragments with protein kinase and $ATP\cdot Mg^{2+}$ increased Na^+/K^+ ATPase activity by an average of twofold (values above represent the mean ±s.e.m. for 8 experiments). The extent of activation was 63–180%; in 1 experiment no effect was observed. The activation of Na^+/K^+ ATPase activity was statistically significant ($P<0.05$, paired analysis). ATPase activity assayed in the absence of Na^+ was not significantly altered by protein kinase (0.194 ± 0.07 compared with 0.185 ± 0.06 μmol per min per mg). The Na^+/K^+ ATPase activity of membrane fragments exhibited several characteristics[53,54] of a Na^+/K^+ pump; inhibition by ouabain (10^{-3} M), F^- and Be^+; low apparent K_m for ATP (<50 μM); stability to mild treatment with SDS; ability to form an acid-stable, base-labile phosphoprotein; turnover number of 10^4 min^{-1} calculated from phosphoprotein and ATPase values.

Cyclic AMP-dependent stimulation of the Na^+/K^+ ATPase

A series of experiments was carried out to determine the manner in which isoprenaline affects Na^+/K^+ pump activity. The effects on the pump apparently result from interaction with a β-receptor, as the stimulation of ^{42}K influx by isoprenaline (10^{-5} M) was fully blocked by 10^{-6} M pindolol. Furthermore, the effects on the pump seem to be mediated by an increase in cyclic AMP, as dibutyryl cyclic AMP (10^{-4} M) caused an increase in ^{42}K influx identical in both magnitude and time course to that produced by isoprenaline (data not shown).

As protein kinases have been reported to affect Na$^+$/K$^+$ ATPase activity in other systems[35–38], we investigated the possibility that Na$^+$/K$^+$ ATPase may be stimulated as a consequence of cyclic AMP-dependent protein phosphorylation. Membrane fragments prepared from isolated smooth muscle cells contain an ATPase activity dependent on the presence of both Na$^+$ and K$^+$ which has characteristics similar to 'sodium pump' ATPases of other tissues (Table 1). Reacting these membrane fragments with cyclic AMP-dependent protein kinase increased ATPase activity (Table 1, Fig. 3). As seen in Fig. 3, the extent of ATPase stimulation approached a maximal value with increasing amounts of protein kinase. This stimulatory effect of protein kinase seems to result from a change in the Na$^+$/K$^+$ ATPase, as activity assayed in the absence of Na$^+$ was not affected (Table 1). Finally, the stimulation was blocked by protein kinase inhibitory protein, suggesting that the change in Na$^+$/K$^+$ ATPase specifically results from phosphorylation catalysed by the protein kinase (Fig. 3).

Na$^+$/K$^+$ transport and relaxation

Experiments were carried out to investigate the coupling between the cyclic AMP-dependent stimulation of Na$^+$/K$^+$ transport and the cyclic AMP-dependent relaxation. To assess whether these two events are causally linked, we examined the effect of isoprenaline on contractility in the presence of ouabain or in K$^+$-free medium, conditions in which Na$^+$/K$^+$ transport should be limited. In our standard medium containing 3 mM K$^+$, isoprenaline inhibited the contractile response to carbachol by 53%; however, when the cells were resuspended in nominally K$^+$-free medium just before exposure to isoprenaline, only a 16% inhibition was observed (Table 2). However, removal of external potassium had no effect on the response to carbachol. An even more striking attenuation of relaxation was observed when ouabain was used to limit Na$^+$/K$^+$ transport (Table 2).

Table 2 Effects of changes in extracellular K$^+$ and ouabain on the response to isoprenaline

Cell suspension medium	% Inhibition of contractility by isoprenaline	No of experiments
Amphibian physiological saline (APS)	50±15	3
APS+ouabain (5×10^{-4} M)	−27±32	
APS	53± 8	5
K$^+$-free APS	16±23	
APS	30± 7	5
90 mM K$^+$/APS	43±16	

The inhibitory effects of (10^{-5} M) isoprenaline on the contractile responses to carbachol (10^{-6}–10^{-4} M) were compared in aliquots of cells isolated as a group, but then divided so that half were suspended in normal amphibian physiological saline (3 mM K$^+$) and the others were suspended in modified amphibian physiological saline[25]. K$^+$ concentration changes were effected by molar substitution of K$^+$ salts for Na$^+$ salts For the groups containing ouabain or K$^+$-free medium the effect of isoprenaline was determined within 30 s of accomplishing the change from APS to the modified medium, this protocol was chosen to minimise changes in ion gradients which would eventually follow inhibition of the Na$^+$/K$^+$ pump For the cells exposed to 90 mM K$^+$, the effect of isoprenaline was determined 15 min after raising the extracellular K$^+$, this period of time was chosen to allow the cells to relax following the initial phasic contraction induced by exposure to high K$^+$ levels To test for the inhibitory effect of isoprenaline on contractility, aliquots were preincubated with isoprenaline (10^{-5} M) for 9 s before testing responsiveness to a 6-s carbachol exposure Contractility was assessed as described in Fig 1. Intracellular microelectrode recordings reveal that increasing the extracellular K$^+$ to 90 mM causes a sustained, almost complete depolarisation[31]

Thus, an increase in Na$^+$/K$^+$ pumping seems to be essential to the isoprenaline-induced relaxation.

We next considered the manner in which an increase in Na$^+$/K$^+$ pump activity might lead to a decrease in Ca^{2+} availability and thus relaxation. Two hypotheses are consistent with our present understanding of Ca^{2+} movement in smooth muscle. The first is that a decrease in calcium permeability might result from the hyperpolarisation which accompanies increased Na$^+$/K$^+$ pump activity[39–42]. Alternatively, the decrease in internal Na$^+$ generated by increased Na$^+$/K$^+$ pump activity might accelerate Na$^+_{in}$/Ca$^{2+}_{out}$ exchange in the plasma membrane and/or sarcoplasmic reticulum[43–46]. Although our understanding of the link between Na$^+$/K$^+$ pump activity and relaxation is incomplete, a change in membrane potential does not seem to be essential for isoprenaline-induced relaxation. This follows from the observation that the inhibitory effect of isoprenaline was unaffected by depolarisation of the cells with 90 mM K$^+$ (Table 2).

We are thus left with the possibility that increased Na$^+$/Ca^{2+} exchange is responsible for linking Na$^+$/K$^+$ pump activity with relaxation. Experiments in which extracellular Na$^+$ was altered suggest that Na$^+$/Ca^{2+} exchange may be important for the control of intracellular Ca^{2+} in these smooth muscle cells, as it is in other smooth muscle preparations[43–46]. Specifically, exposure of cells to Na$^+$-free medium caused contraction. The $t_{1/2}$ for this response averaged 15 min (four experiments) and the magnitude of the observed contraction was equivalent to the maximal contractile response obtained with carbachol. These data suggest that Ca^{2+} sequestration depends on the Na$^+$ gradient, and that a change in this gradient produced by stimulation of the Na$^+$/K$^+$ pump may lead to relaxation.

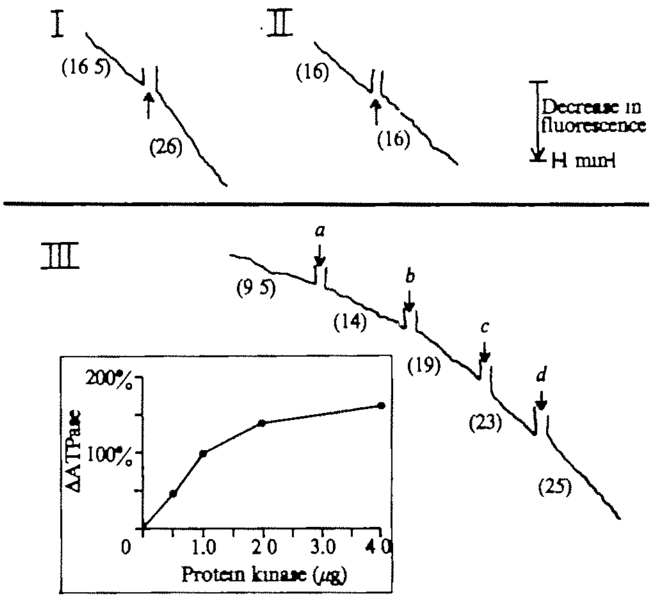

Fig. 3 Stimulation of ATP hydrolysis by cyclic AMP-dependent protein kinase. Membrane fragments were prepared from isolated smooth muscle cells by differential centrifugation of extracts prepared in sucrose (0.25 mM), imidazole (50 mM) and EDTA (10 mM) buffer, *p*H 7 2. Fragments sedimenting between 1.2×10^3 *g* and 4×10^3 *g* were assayed for ATPase activity fluorometrically[55]. ADP formation was followed as the decrease in fluorescence on conversion of NADH to its oxidised form, the rate of change being indicated in parentheses Vertical bar represents 5 nmol of NAD$^+$ In traces I and II, 10 μg of membrane fragments were used. The effects of cyclic AMP-dependent protein kinase (2 μg added at arrow) were tested in the absence (I) and presence (II) of cyclic AMP-dependent protein kinase inhibitory protein[56] added before the membrane fragments III, 20 μg of membrane fragments (a different preparation from that used in I and II) was assayed in the presence of increasing amounts of protein kinase *a*, 0 5 μg protein kinase was added, *b*, additional 0 5 μg, *c*, additional 1.0 μg; *d*, additional 2 0 μg. Note that protein kinase stimulation of ATPase activity seems to be saturable (see insert). Control studies revealed that the stimulation of ATPase activity could not be accounted for by ATPase activity of the protein kinase or by protein kinase-induced alterations in the activity of the coupling enzymes (pyruvate kinase and lactate dehydrogenase) used in the assay. It is unlikely that the stimulation of ATP hydrolysis represents a rapid turnover of a phosphoprotein in the membrane fragments catalysed by the protein kinase and a membrane-associated phosphoprotein phosphatase, as maximal catalytic activity of protein kinase could produce less than 10% of the observed stimulation of ATP hydrolysis

Model for isoprenaline action

A model for the mechanism underlying the relaxation induced by isoproterenol is shown schematically in Fig. 4. This hypothesis accounts for all of the observations on isolated smooth muscle cells. This scheme also includes what we believe to be the most plausible means by which stimulation of the Na^+/K^+ pump leads to relaxation. The essential features of the scheme are: (1) isoprenaline binds to the β-adrenergic receptor, causing a rapid increase in intracellular cyclic AMP which in turn activates cyclic AMP-dependent protein kinase; (2) the increased activity of protein kinase results in phosphorylation of a protein associated with the Na^+/K^+ ATPase, thus increasing pump activity; (3) as a consequence of increased pump activity, intracellular K^+ rises and intracellular Na^+ falls; (4) the increased Na^+ gradient would accelerate the rate of Na^+/Ca^{2+} exchange, resulting in increased Ca^{2+} efflux from the cytoplasm; (5) the change in Ca^{2+} distribution would decrease contractility.

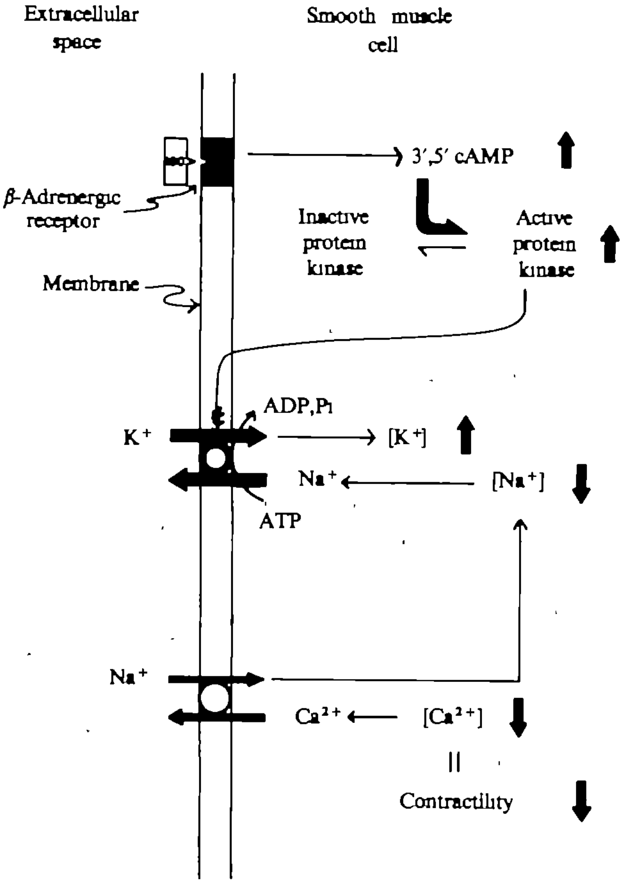

Fig. 4 Scheme for β-adrenergic relaxation of smooth muscle. It is proposed that β-adrenergic agents stimulate the Na^+/K^+ pump through cyclic AMP-dependent protein phosphorylation, and thereby produce relaxation. Although the link between enhanced pump activity and relaxation has not been fully explored, the involvement of a Na^+/Ca^{2+} exchange process seems to be most reasonable. The model shows Na^+/Ca^{2+} exchange accelerated at the plasma membrane, but a similar Na^+/Ca^{2+} exchange system in the sarcoplasmic reticulum and/or mitochondrial membranes might also contribute to the observed decrease in Ca^{2+} availability. Further details regarding this scheme and the evidence supporting are given in the text.

The above description indicates the interdependence of cellular processes which are affected by isoprenaline. Implicit in this scheme is a specific kinetic relationship between these events. First, the changes shown in Fig. 4 will be initiated in a sequential manner beginning with an increase in cyclic AMP. Second, the changes will induce a persistent activation of the Na^+ pump such that relaxation is maintained. This activation initially elicits large changes in Na^+ and K^+ fluxes, but the resultant changes in ion gradients soon slow pump activity towards basal levels. Similar kinetics for enhanced Na^+/Ca^{2+} exchange would also be expected. The large rapid increases in ion movements would rapidly bring the smooth muscle cell to a more relaxed state. Relaxation could then be maintained by only a small persistent increase in Na^+/K^+ and Na^+/Ca^{2+} transport processes.

It seems likely that the mechanism outlined above plays a central part in β-adrenergic relaxation of other types of smooth muscle, although additional factors may also be involved. Tests for the involvement of our proposed mechanism in other tissues will probably require the use of isolated cells derived from each tissue type, so that the brief, large changes in ion movements will not be obscured by the diffusion delays and ion binding which complicate studies in intact tissue.

We thank Philip Merriam, Cathy Bulman, Elaine Fuller and Kris Kelley for technical assistance. This work was supported in part by grant HL14523 (NIH). During this work, C.R.S. was supported by postdoctoral fellowships (American Heart Association 13-432-756 and NIH 5 F32 AM05653-02) and F.S.F. was the recipient of a Research Career Development Award (HL00048).

Structure of the backbone in myosin filaments of muscle

John S. Wray

Biophysics Institute, Aarhus University, Aarhus, Denmark
Rosenstiel Basic Medical Sciences Research Center, Brandeis University, Waltham, Massachusetts 02154

New X-ray data suggest how myosin rods, themselves α-helical coiled coils, form the thick filament backbone of crustacean muscles by additional supercoiling. Natural transformations of this structure may describe the myosin backbone in many other animals also.

THE thick filaments of striated muscle are remarkable bipolar structures. The α-helical rod portions of the myosin molecules are packed densely in the backbone, yet the enzymatic portions (pairs of 'heads' or 'cross-bridges') lie at the filament surface where they can participate in the tension-generating interaction with actin[1,2]. While the ordered helical array of relaxed cross-bridges has been described for several muscles, the internal architecture that defines it is unknown: neither X-ray diffraction nor electron microscopy has revealed the structure of the backbone. Studies of the overlaps between molecules in aggregates of myosin subfragments formed *in vitro* have suggested likely packing arrangements of the myosin rods in native filaments[3–5]. Perhaps the most attractive of such models are those in which all myosin molecules have identical environments and are thus 'equivalent' to each other[6]. Knowledge of backbone structures in different muscles will help in understanding the design problem of accommodating both the structural and the enzymatic functions of myosin.

In this article, I discuss thick filament structure in the light of new X-ray diffraction data from crustacean muscles. The X-ray patterns include myosin reflections intermediate between the small-angle diffraction due to the cross-bridge array and the wide-angle diffraction from the α-helical polypeptide conformation in the backbone. These reflections suggest that the backbone has a simple cable-like structure, and indicate its relation to the surface array of bridges. Myosin filament structure in other muscles is discussed briefly in terms of plausible transformations of the structure described for the crustaceans.

Symmetry and polymorphism of the surface lattice

In the fast muscles of decapod crustaceans[7], the thick and thin filaments form a lattice resembling that in insect flight muscles, and the diffraction from the thin filaments has been discussed previously[8]. The myosin filaments are not held in precise transverse register as they are in some insect muscles, and their diffraction is unsampled. Reflections due to myosin in the small-angle X-ray pattern from a relaxed fast lobster muscle (Fig. 1*a*) include a strong meridional reflection at 145 Å with an off-meridional subsidiary maximum, and non-meridional layer lines at 308 Å and 274 Å. All these reflections become weaker in rigor, when bridges are displaced from their ordered positions round the thick filament and attach to actin. The 145-Å layer line indicates that cross-bridges are located at 145-Å intervals along the thick filament, as found for many other muscles. The non-meridional layer lines reflect the screw symmetry, or rotation between adjacent 145-Å levels (just as frog muscle patterns, for example, indicate a screw symmetry described by giving the helical repeat of the most prominent cross-bridge helix as 429 Å (ref. 9)). The screw symmetry indicated by the lobster pattern in Fig. 1*a* differs from that in muscles studied hitherto, the myosin helical repeat being 308 Å. The black spots in Fig. 3*a* illustrate this surface symmetry. The X-ray pattern is much simpler than that from frog muscles, where certain 'forbidden' reflections[9] may indicate a surface lattice in which structure units are not perfectly equivalent.

The cross-bridge reflections reveal the screw symmetry very precisely, but derivation of rotational symmetry (the number (*N*) of structure units or myosin molecules per 145-Å level) is less easy. This is because the diffraction depends mainly on the bridge conformation and on the intrinsic form of the surface lattice, and is changed only slightly by increase of *N* with proportional increase in radius from the filament axis[10]. (A preliminary study of lobster muscles[10] noted that the layer lines resemble those given by insect flight muscles[11] in intensity and

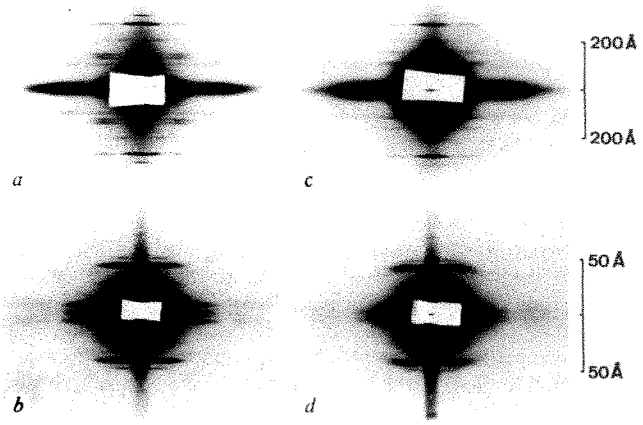

Fig. 1 X-ray diffraction patterns from crustacean muscles, chemically skinned[8] and examined in the relaxed state in a solution containing 90 mM KCl, 8 mM $MgCl_2$, 2 mM EGTA, 10 mM histidine, 2 mM Na_2ATP, 1 mM NaN_3, *p*H 7.0 at 4 °C. X-ray patterns were obtained using conventional mirror-monochromator cameras[9] and specimen–film distances of 36 cm (*a*, *c*) and 12 cm (*b*, *d*). *a*, *b*, Patterns from a fast abdominal flexor of the lobster. *a* is the small-angle pattern, showing actin layer lines at 387, 194 and 129 Å, and myosin layer lines at 308, 274 and 145 Å. The actin layer lines were enhanced, and these myosin layer lines weakened, in patterns from the same muscles in rigor. *b* is a more intense medium-angle pattern. Actin layer lines at 59 and 51 Å are prominent; the conspicuous layer line of axial spacing about 350 Å remained unchanged in the rigor pattern. Certain weak reflections in the small-angle pattern were also unchanged in rigor, such as a subsidiary maximum of the strong layer line at 380 Å and a layer line at 95 Å. *c*, *d*, Patterns from a slow muscle of the lobster crusher claw. Slow muscles gave patterns with a higher diffuse background than fast muscles, but layer lines corresponding to those from fast muscles were clearly visible. The small-angle off-meridional reflections occurred at 350 and 248 Å, and the myosin layer line which was unchanged in rigor fell at about 600 Å.

0028-0836/79/0277—0037$01.00

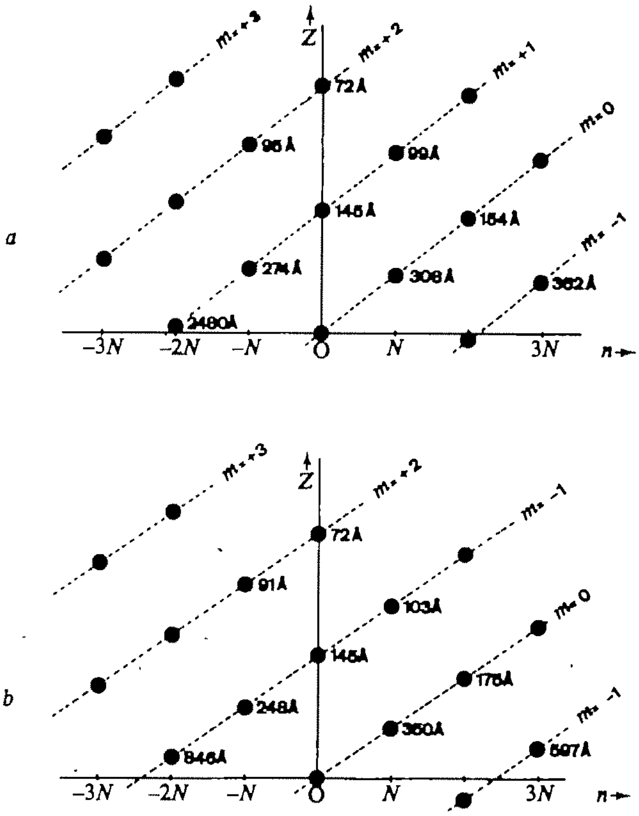

Fig. 2 Diagrams of myosin layer lines *a*, General representation of the diffraction expected from a helical array with the symmetry being indicated by the myosin diffraction in Fig. 1*a*. Axial positions (Z) of expected layer lines are plotted against their Bessel function orders (n), reflections can be referred to by n and by the value of m assigned to the dotted lines (in the convention of helix diffraction theory[23]), and certain axial spacings are indicated numerically Individual nodes are represented in the observed diffraction by reflections whose radial positions depend on the radii from the filament axis of the structures generating them. The diffraction in Fig. 1*a* is interpreted through the diagram as follows The strong layer lines at 308, 274 and 145 Å originate from the surface array of cross-bridges, and generate the innermost reflections ($m=0$, $n=N$), ($m=1$, $n=-N$) and ($m=1$, $n=0$) respectively. Bridges do not contribute significantly to any wider-angle reflections, which correspond to other sets of helical tracks through the surface lattice. The reflection ($-1, 3N$) at 352 Å has special significance, as a strong layer line at this spacing is due to subfilaments interconnecting the surface lattice; the value $n=3N$ corresponds to there being $3N$ subfilaments. (The backbone is not formed from smooth strands; other variations of density, distributed in conformity with the myosin surface lattice, cause weak diffraction at other nodes, such as a subsidiary peak on the 308 Å layer line ($0, N$) and presumably part of the meridional intensities at orders of 145 Å.) Many reflections thus include contributions from both bridges and backbone, located at different radii from the filament axis, and only in special cases will profiles be interpretable in terms of diffraction from simple structures. *b*, Same diagram for the slow muscles. N here takes a different value. These diagrams represent two stages in the continuous transformation of the diffraction that would accompany progressive twisting of the filament. The various fast crustacean muscles could be represented by a series of diagrams with spacings close to those in (*a*) The spacing of the ($-1, 3N$) reflection equals the helical repeat of the subfilaments in each case. Generally, such diagrams can describe the diffraction from any helical cross-bridge array. Untwisting the filament slightly beyond state (*b*), the spacing of ($0, N$) reaches 385 Å as observed for insect muscle[11], and ($-1, 3N$) then has a spacing of 1150 Å. Untwisting further, until ($0, N$) falls at 435 Å, the screw symmetry becomes that observed for frog muscles[9]. ($-1, 3N$) lies on the equator in the latter case: thus, if the filament were formed from subfilaments homologous to those of crustacean muscles, these would run parallel to the filament axis.

might be explained by the sixfold rotational symmetry widely accepted for insect muscle: but, as discussed below, this symmetry for lobster muscles now seems unlikely.) Neither the value of N nor the conformation of each pair of heads is required for discussing the relationship between myosin symmetry and the structure of the backbone.

The myosin screw symmetry in fast crustacean muscles depends on the anatomical location of the muscle and on species. For example, the principal cross-bridge helical repeat was 300 Å in many fast muscles of crayfish and 308 Å in certain fast lobster muscles, but 310 Å in the fast muscles of crayfish legs, 315 Å in those of the lobster left claw, and 318 Å in those of both crayfish claws. Thus, while myosin filaments may have the same screw symmetry in the skeletal muscles of all vertebrate animals, the fast muscles even of one crustacean species present a family of non-integral myosin helices differing slightly in filament twist.

Diffraction from the myosin backbone

The diffraction expected from a representative member of this family is summarised in Fig. 2*a*. The observed cross-bridge reflections (at 308 Å, 276 Å and 145 Å) represent few of the full set that would result from a perfectly ordered helical array, and this paucity of diffraction indicates that the bridges are considerably disordered about their average positions. More intense patterns from the crustacean muscles did show other myosin reflections, but these were not due to bridges, as they were unchanged in patterns from rigor muscles. The most prominent was a layer line (Fig. 1*b*) whose spacing varied with the screw symmetry of the filament so as always to correspond to that of one particular outer reflection (at 352 Å in the case depicted by Fig. 2*a*). The characteristic radial profile of this layer line is shown in Fig. 4*a*.

Reflections unaffected by the transition to rigor but occurring at spacings related to those of the myosin surface lattice are expected from the myosin backbone and may reveal its structure. First, as different nodes in Fig. 2 correspond to different sets of helical tracks through the surface lattice, the prominence of one particular layer line means that the structure can, at low resolution, be considered as comprising uniform helical strands following one particular direction. Second, the profile of this layer line is characteristic of a cable-like structure whose density is concentrated near a single radius, and whose strands have a diameter of about 40 Å and are packed closely with their neighbours (Fig. 4*b*). The backbone is shown in Fig. 3*a* as a cable whose strands connect up the cross-bridge surface lattice in the direction corresponding to the prominent layer line from the backbone. This structure, apparently identical in relaxed and rigor states, could exist over most of each half of the myosin filament, but will not describe the packing at the ends and centre. Its absolute hand is unknown and is drawn arbitrarily. The hollow core is in agreement with the appearance of a weakly staining centre in crustacean filaments[7]; this observed appearance is variable, perhaps because the core contains small but variable amounts of paramyosin (whose organisation is not revealed by the present X-ray data).

The relationship of cross-bridge positions to the backbone in Fig. 3*a* is such that, with N myosin molecules per 145 Å along the filament, there are $3N$ subfilaments. (The value $N=4$, as drawn, seems the most probable if the tubular appearance of Fig. 3*a* is identified with that in electron microscope images, because the number ($3N$) of subfilaments, separated centre-to-centre by 40 Å as indicated by the X-ray pattern, must be about 12 to generate the observed[7] outer diameter of about 200 Å.) The X-ray patterns also contain information about the packing of myosin rods within individual subfilaments. But the 40-Å subfilament diameter directly suggests a cylindrical group of three myosin rods (each a 2-stranded α-helical coiled coil). Moreover, the repeat length along each individual subfilament in Fig. 3*a* is 435 Å, so the length of the crustacean myosin rod[12], slightly more than 3 × 435 Å, would likewise suggest that three overlapping rods comprise each subfilament over most of its length. The myosin rods forming each subfilament must twist round each other if all the myosin heads are accessible to the filament surface.

Diversity of crustacean filaments

The variation of screw symmetry was the only indication in the X-ray patterns that myosin structure in fast crustacean muscles is polymorphic. It corresponds to a slight variation in the angle at which the subfilaments twist round the filament. The versatility of the packing is further illustrated by the slow muscles of the crustaceans. Here the thick filaments have a larger (280 Å) diameter[7], reflected in the X-ray pattern (Fig. 1*c*) by, for example, a different profile of the 145-Å layer line. But although the two off-meridional cross-bridge reflections indicate a cross-bridge helical repeat of 350 Å, and the layer line from the subfilaments has an axial spacing of about 600 Å (Fig. 1*d*), the intensities and profiles of these layer lines are not greatly changed from those in the several fast muscles. Thus an essentially invariant relationship of relaxed cross-bridges to backbone subfilaments seems to be intrinsic in the surface lattice of the fast and slow muscle myosin filaments. The slow muscles differ merely in a smaller twist of the subfilaments round the filament, and in higher rotational symmetry (probably increased from four- to fivefold (Fig. 3*b*)).

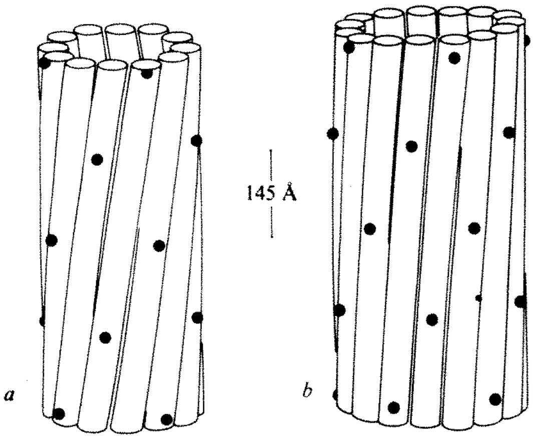

Fig. 3 Relationship of cross-bridge positions to subfilament organisation. *a*, Black spots represent the positions of cross-bridges, as indicated by those reflections in Fig. 1*a* which weaken in rigor. Further aspects of bridge arrangement, such as radial position and conformation, are not discussed here. The backbone is shown as strands connecting this lattice in the helical direction corresponding to the prominent backbone layer line; subfilament diameter and separation were derived from this layer line (Fig. 4). The several fast crustacean muscles examined would have uniform rotational symmetry, but slightly different screw symmetries. *b*, Similar drawing for slow muscle myosin filaments. Both the rotational and the screw symmetry differ from (*a*). The essentially conserved relationship between bridges and subfilaments probably extends to finer details of the structure than are indicated here.

Subfilament structure of myosin filaments

These models for myosin filaments are of a type discussed by Cohen[6]. Re-emphasising that the filaments might be constructed so that all myosin molecules are equivalent, Squire[5,13] has enumerated such packing arrangements more fully. The fast and slow muscles of crustaceans illustrate a central point of Squire's general thesis: that whatever the local packing relationships of myosin rods, the unit cell of the surface lattice may change little if the cross-bridge arrangements of different muscles are generated by changes of rotational and screw symmetry. The particular packing of rods discussed by Squire[14] as a model for all myosin filaments is more compact than the present structure: groups of rods do not twist round each other in subfilaments near the surface, but instead form radial sheets which more nearly fill the filament centre. The present X-ray data require a backbone organised so that there is a marked circumferential repeat of 40 Å rather than the less 'contrasty' surface appearance of the model favoured by Squire[14].

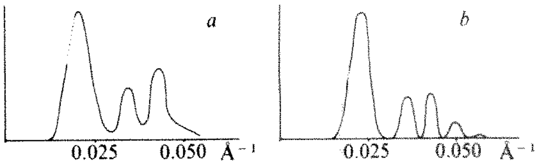

Fig. 4 *a*, Observed radial profile of the strong layer line at 352 Å, indexed as $(-1, 3N)$ in Fig. 2*a*. Dashed line indicates uncertainty due to incomplete separation from nearby layer lines. *b*, Intensity calculated[24] for the layer line at 352 Å from the cable-like backbone in Fig. 3*a*, normalised to same peak height as (*a*). Subfilaments, centred at 84 Å radius, were each represented by 3 uniformly intertwining myosin rods (smooth cylinders of 8.5 Å radius) centred 12.6 Å from their local axis. The 352-Å layer line is the 'pitch' layer line of the 'major helix'[24], and is by far the strongest of the layer lines from the structure. In terms of Bessel functions (J), the profile is given by

$$[J_{12}(2\pi \times 84R)J_0(2\pi \times 12.6R)J_1(2\pi \times 8.5R)/(2\pi \times 8.5R)]^2$$

Cables with more or fewer subfilaments, but with the same (~40 Å) separation between neighbours, give similar profiles: but the 12-fold symmetry appears the most probable (see text).

There are two reasons why X-ray patterns from crustacean muscles are especially informative about backbone structure. First, the pronounced twisting of the subfilaments round the filament means that a key diagnostic layer line can be observed, separated from the equator of the X-ray pattern. Second, the distinct but related filament structures in the various crustacean muscles indicate the conserved and the variable aspects of the molecular packing. Corresponding data from other animals will establish how far myosin backbones in muscles outside this restricted class can be described by the present model. X-ray data on cross-bridge arrays in some invertebrate muscles apart from crustaceans (such as *Lethocerus* flight muscle[13] and *Limulus* muscle[15]) can be interpreted in terms of a simple helical surface lattice: backbone models for these filaments must again be such that myosin molecules occupy equivalent positions. In fibrillar insect flight muscles, for example, the 385-Å myosin helical repeat[11] may result from further change of screw symmetry in a filament of the crustacean type, as a reflection with the axial spacing of roughly 1,150 Å, as expected for diffraction from subfilaments (see legend to Fig. 2), is observed at 40 Å radius (my unpublished results on bee and fly muscles, and ref. 16). The flight muscles of some dragonflies (Odonata) are non-fibrillar, and support this extension of the crustacean model to include insect filaments. Their myosin symmetry differs from that in the fibrillar muscles: the helical repeat is about 350 Å, and the subfilament diffraction is very like that of slow crustacean muscles. Application of the subfilament model to insect as well as to crustacean filaments does not demand the same rotational symmetry in both cases, but does leave the puzzle that, just as argued above for crustaceans, the 150–200-Å diameter of insect filaments observed by electron microscopy[17] could accommodate 12 subfilaments, and thus 4 myosin molecules per 145 Å of filament length, while other evidence (see ref. 18) suggests 6 myosins per 145 Å for insect muscle.

Vertebrate and other filaments

In some other muscles, such as vertebrate striated muscles[9] and the striated adductor of the scallop[10,19], X-ray evidence suggests that the cross-bridge array departs from equivalence in that adjacent 145-Å levels are not identical (possibly because of non-equivalent packing in the backbone or a perturbation due, for example, to proteins other than myosin). Here I consider non-equivalence only in the context of the present subfilament model, retaining the 435-Å repeat within the subfilament and the 145-Å stagger between subfilaments as conserved features. Filaments built in this way provide equivalent environments for all myosin molecules only when each subfilament, at every level at which cross-bridges emerge from it, appears at the filament surface in an identical way. Disposition of the subfilaments to form tubular filaments in crustaceans fulfills this requirement in a simple manner (which, however, leaves a large core). But strict equivalence is not necessarily a significant property for the cross-bridge array: the departures detected by X-ray diffraction may be rather small, and may leave all myosin molecules functionally equivalent in their ability to interact with actin. More compact structures would result from an orderly collapse of the tubular form (with loss of perfect helical symmetry, as cross-bridges from more central subfilaments would necessarily adopt slightly different resting configurations). Collapse is plausible only when the subfilaments run almost parallel to the filament axis (as inner and outer subfilaments otherwise acquire different axial repeats), or when the filament is very short, but could in either of these cases occur with little change in the pattern of intermolecular connections. Vertebrate skeletal myosin filaments might exemplify this more radical transformation of the crustacean structure, as their screw symmetry is such that the subfilaments would run parallel to the axis (see legend to Fig. 2). Collapse could give solid polygonal filaments as observed for frog and fish muscles[20,21]. The consequent non-equivalence would be additional to that resulting because C-protein is not located according to the 143-Å repeat of myosin[22]. Such a model for vertebrate filaments remains entirely speculative until direct information about their backbone structure is obtained, but meanwhile illustrates one natural way for more specialised myosin structures to be generated from a simple, versatile and widespread design.

I thank Drs Jack Lowy, Carolyn Cohen and Peter Vibert for advice, John Pedersen for technical help, Dr John Squire for criticism, and EMBO for a long-term fellowship. Additional support was provided by grants from NSF (PCM76-10558), NIH (AM17346) and MDAA to Dr C. Cohen.

Are there organic grains in the interstellar medium?

THE possibility that organic compounds exist in or on interstellar grains has received much attention recently. It has been suggested that grains consist of polysaccharides[1], carbonaceous compounds[2] or aggregates of a variety of organic compounds[3]. While it is easy to visualise how some of these materials could form in the interstellar medium (for example, by the random accretion of C, N, O and H) it is not certain that appreciable quantities of such grains actually exist. With the availability of high quality infrared (IR) spectra of a variety of sources we show here how to determine the fraction of interstellar carbon bound in complex molecules of this sort.

Virtually all compounds containing C and H possess an IR absorption band due to the excitation of the C–H stretching vibration between 3.3 and 3.4 μm. This band usually has a width of ≃0.05–0.2 μm in condensed phases. As noted by Knacke[2] this band will be present even in polymeric or tarry materials as found, for example, in carbonaceous chondrites. The persistence of a band at 3.3–3.4 μm in all organic systems implies that observations of the spectrum of interstellar dust in this region can be used in a determination of the abundance of organic solids in interstellar dust.

Figure 1 shows a plot of τ(3.3–3.4 μm) against A_v, the visual extinction in magnitudes, for a variety of organic compounds representative of several chemical classes. These optical depths at 3.3–3.4 μm would be obtained if all interstellar C were obtained in these molecules. They are calculated on the basis of an extinction $A_v = 1.6$ mag per kpc H atom cm^{-3} using the normal cosmic abundance of carbon[4]. Data on the strength of the 3.3–3.4 μm band was obtained from standard sources[5,6]. Cross-sections vary from a low of 3.4×10^2 cm^2 g^{-1} for C_6H_6 to 8.4×10^3 cm^2 g^{-1} for $C_{42}H_{88}$ (2,2,4,15,17,17-hexamethyl-7,12-di(3,3,5-trimethyl hexyl)octadecane). It can be seen that the largest values of τ are produced by alkanes. The cyclic ether, propylene oxide also produces strong absorption at 3.3–3.4 μm. Aromatic compounds such as C_6H_6 are relatively weak absorbers although substitution with any CH bearing group (such as *p*-xylene) greatly increases the 3.3–3.4 μm band strength. Polymers such as polyethylene and polyvinyl alcohol are strong absorbers.

The corresponding relationship between equivalent width, W, in μm and A_v is

$$\frac{W}{A_v} = 2.9 \times 10^{-2} \frac{I}{n_c} \tag{1}$$

where I = integrated 3.3–3.4 μm band intensity in units of 10^4 l cm^{-2} mol^{-1} and n_c = number of carbon atoms in each

0028-0836/79/0277—0040$01.00

absorbing molecule. This equation is obtained from Wexler's expression[6] for integrated intensity in these units, $I = \Delta\nu \log_{10}(\mathcal{I}_0/\mathcal{I})/(10^4 CL)$ where $\Delta\nu$ is FWHM if cm^{-1}, $\mathcal{I}/\mathcal{I}_0 = e^{-\tau}$ is the intensity ratio in the line, C is the concentration in moles per 10^4 litre, and L is the path length in cm. Most bands have intensities, in these units, in the range 0.01–1, (ref. 6). For small τ, $W = \tau\Delta\lambda$, and so rearranging, with some attention to units, gives $W = N\lambda^2 I/2.62\times10^{20}$. W and λ are in μm, and N is the column density (cm^{-2}) of absorbing molecules. Thus $N = [C]L/n_0$ where $[C]$ is the total available carbon density (cm^{-3}). With extinction A_v of 1.6 mag kpc^{-1} per H-atom, then $A_v = 1.6[\text{H}]L/3\times10^{21}$. Using the cosmic abundance of carbon, the ratio of W to A_v gives equation (1). Since $I \simeq n_0 G$ where G = integrated intensity per structural unit (CH, CH_2 or CH_3),

$$W \simeq 2.9\times10^{-2} A_v G \qquad (2)$$

G is quite different for molecules of different chemical classes but is relatively constant for molecules of the same class[6]. Figure 1 shows data for a selection of molecules that are representative of the major chemical classes. Obviously under interstellar conditions a variety of molecules would be expected and so an average would have to be taken to determine the total expected 3.3–3.4 μm optical depth.

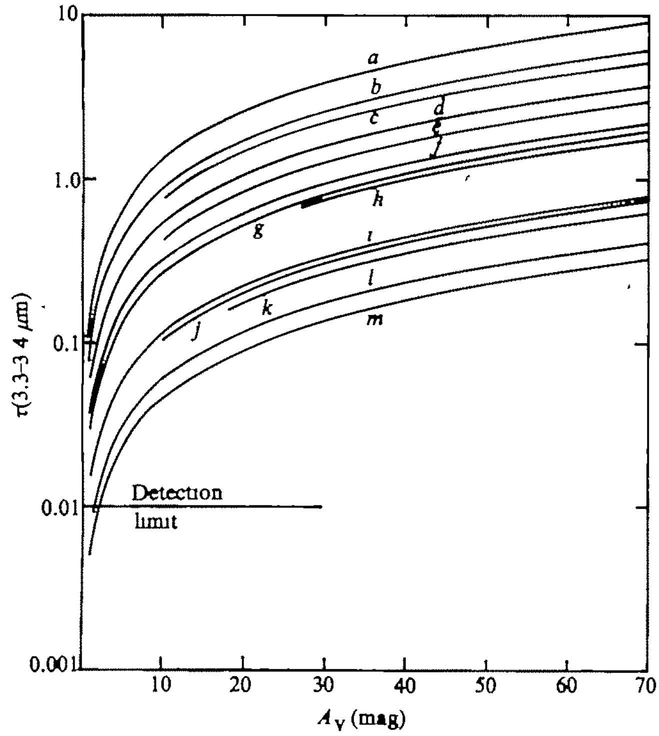

Fig. 1 Predicted optical depth at 3.3–3.4 μm, τ due to organic compounds on grains plotted against visual extinction A_v in magnitudes. A detection limit provided by recent observations[7] is shown at $\tau = 0.01$. Failure to detect the presence of a 3.3–3.4 μm band with this amplitude in an object with $A_v = 70$ mag would imply that < 0.2% of interstellar carbon is present as alkanes: *a*, $C_{42}H_{88}$; *b*, *n*-hexane; *c*, propylene oxide; *d*, 1-pentanol; *e*, *n*-butyl ethyl ether; *f*, polyethylene, *g*, acetone, *h*, poly-vinyl alcohol; *i*, *p*-xylene; *j*, 1–3 butadiene, *k*, pyridine; *l*, 3-octyne; *m*, benzene.

A line in Fig. 1 indicates the current detection limit for spectral features in the 2.9–3.4 μm region as obtained, for example, by McMillan[7]. Spectroscopic data of high quality obtained by Merrill *et al.*[8] for a variety of highly obscured objects shows no evidence for detectable 3.3–3.4 μm absorption even in objects with $A_v \gtrsim 50$ mag. It is also significant that no absorption appears at 3.3–3.4 μm even in objects with well developed 3.08 μm ice bands. These observations, together with the curves given in the Fig. 1 suggest that the limits shown in Table 1 can be placed on the abundance of organic compounds on dust in the interstellar medium.

Table 1 Abundance limits of various chemicals in the interstellar medium

Chemical class	Abundance limit
Alkanes	<1% of C
Cyclic ethers	<1%
Non-cyclic ethers	<2%
Alcohols	<2%
Polymers	<2%
Ketones	<2%
Alkenes	<10%
Alkynes	<10%
Aromatics	<10%

These limits are expressed in terms of the percentage of carbon that could be present in molecules of each class without producing $\tau(3.3\text{–}3.4) > 0.05$ for $A_v = 70$ mag. As all molecules absorb at the same wavelength it is not possible to sum abundance limits in Table 1 to permit the dispersal of larger amounts of carbon in organic compounds. Thus if 1% of C were in alkanes, $\tau = 0.05$ would be produced by these molecules alone implying that the abundances of all other types of organic molecule would be much less than those given in Table 1.

We conclude that no spectroscopic evidence exists to support the contention that much of interstellar dust consists of organic materials. While the presence of trace quantities of organic compounds on grains inside very dense clouds cannot be excluded by available data, the absence of any observation of a 3.3–3.4 μm absorption band even in objects with $A_v \simeq 50$ mag strongly suggests that organic grains constitute at most a minor component of interstellar dust and probably have no observable effect on visual extinction. Certainly the dust that produces the visual extinction in highly obscured sources cannot be composed of organic material. For example, in an object with $A_v = 50$ mag the column density of dust in the form of particles of radius 10^{-5} cm with scattering efficiency $\simeq 1$, is $(NL)_{\text{dust}} = 1.6\times10^{11}\ \text{cm}^{-2}$. For a grain density of 1 g cm^{-3} the mass of dust per cm^2 is 6.4×10^{-4} g cm^{-2}. Then $\tau(3.3\text{–}3.4)\ C_6H_6 = 0.22$ and $\tau(3.3\text{–}3.4)\ C_{42}H_{88} = 5.4$ in this object. Optical depths in this range would certainly be detectable.

Magnetic buoyancy in the Sun

THE concept of 'magnetic buoyancy' was introduced[1] as a possible mechanism by which magnetic fields from within the Sun might come to the surface and contribute to its magnetic activity. We discuss this concept here and consider its effect on solar dynamics.

An isolated flux tube of field strength **B** in a gaseous atmosphère of magnetic permeability μ has a lower thermodynamic pressure p than that of its surroundings, because the total

0028-0836/79/0277—0041$01 00

pressure $p+\frac{1}{2}\mu^{-1}\mathbf{B}^2$ must be the same inside and outside the tube. If the temperatures inside and out are sufficiently close it will then be lighter than its surroundings and will tend to rise by this magnetically-induced buoyancy.

Recently[2,3] it has been argued that this mechanism actually works rather too well for comfort, bringing 100-G flux tubes from all but the bottom quarter of the solar convection zone (depth ~200,000 km) to the surface in a good deal less than the time needed for the generation of these fields by the hydrodynamic dynamo process[4], which is 10 yr, that is, comparable with the time scale of the solar cycle. As far as the origin of these thin flux tubes is concerned, it has been pointed out that a large-scale azimuthal field which decreases with height is unstable[3], again by the mechanism of magnetic buoyancy, and would break up in the required way within a time of order H/V, where H is the scale height for the density ρ and

$$V=B/(\mu\rho)^{1/2} \tag{1}$$

is the Alfvén speed. This 'break-up' time is also much less than 10 yr except at the very bottom of the convection zone. The conclusion of this argument is that the dynamo must function at the very bottom of the zone with a field strength of ~100 G; such a field is barely enough to account for the total flux emerging from the Sun in the course of one solar cycle[3].

As flux tubes rise they encounter lower background pressures and if they are horizontal they expand in cross-section. Their magnetic field therefore drops, and it has been argued[5] that the concomitant reduction in their magnetic buoyancy can substantially increase the time they take to reach the solar surface. The matter is complicated, however, by the fact that by bending, so that some portions are higher than others, the 'crests' can largely retain their magnetic buoyancy by off-loading[1] some of the gas down the arms of the tube to the 'troughs', which proceed upwards rather more slowly as a result. The initial instability mechanism certainly uses this process, so that the most rapidly growing disturbances have non-zero wavelength (in fact, comparable with the magnetic field scale-height) along field lines[6,7], and it is natural to expect this bending of the field lines to persist even when the amplitude of the disturbance becomes large.

Further bending of the tube, of a different kind, will result from the action of the Coriolis force (due to the Sun's angular velocity Ω) on the material sliding down from the crests to the troughs; this imparts an anticyclonic twist ψ to the crests, which as a result do not break the surface quite along a line of latitude. This is thought to explain the fact that the 'leading' sunspot of a bipolar pair is normally closer to the Equator than the 'following' spot[4]. The observations demand that typically $\psi\sim 10°$.

Recent studies of instability by magnetic buoyancy in a rotating system[8-10], however, suggest the solar rotation exerts a much stronger influence than this on the entire mechanism: the dimensionless parameter

$$S=\frac{\Omega H}{V} \tag{2}$$

is large throughout most of the convection zone for an azimuthal field of 100 G, ranging from ~20 at a depth of 30,000 km to ~500 at the bottom of the zone (~200,000 km depth). It turns out that magnetic buoyancy instability does not then develop on the Alfvén time scale H/V at all, but on the much longer time scale

$$T\sim\frac{4\Omega H^2}{V^2} \tag{3}$$

This is ~10 yr at 30,000 km depth, again for a field of 100 G, but far exceeds the time scale of the solar cycle at greater depth. Further, if the effects of turbulent diffusion are taken into account instability does not take place at all unless

$$\mathscr{C}=\frac{V^2}{2\Omega\eta} \tag{4}$$

is greater than about unity. With turbulent diffusivities η of the kind usually envisaged[11,12], that is 10^8–$10^9\ \mathrm{m^2\,s^{-1}}$, $\mathscr{C}$ is ~10^{-3} or so throughout much of the zone.

Suppose, therefore, that the azimuthal field were much larger, say at least 1,000 G. The parameter $\mathscr{C}$ might just about exceed unity (η is somewhat uncertain[12]), while the time scale T ranges from a few weeks at depths of 30,000 km to ~10 yr at 100,000 km. In the bottom half of the convection zone we would not expect even a 1,000-G field to break up by magnetic buoyancy instability within the time scale of the solar cycle.

The most rapidly-growing mode has a wavelength along field lines of order H, as in the absence of rotation, and the original field again breaks up into isolated flux tubes with 'crests and troughs'. What happens to these tubes when they have floated up and distorted a significant amount is beyond the scope of the linear instability theory, but it seems natural to suppose that the rate of rise will then be comparable with the actual gas velocities $\mathbf{u}$ involved, and that the time scale will be comparable with that for the instability. Then the rate of rise and $\mathbf{u}$ will be of the order $V^2/\Omega H$, which is much smaller than the Alfvén speed, and implies that the Coriolis forces (per unit mass) $2\rho\boldsymbol{\Omega}\wedge\mathbf{u}$ and the Lorentz forces $\mu^{-1}(\nabla\wedge\mathbf{B})\wedge\mathbf{B}$ will be of comparable magnitude. This avoids a contradiction that arises if one assumes that rotation plays only a rather minor role and that the rate of rise and $\mathbf{u}$ are of order V (see above): the ratio of Coriolis forces to Lorentz forces is then $\Omega H/V$ and very large (for a 100 G field), indicating that rotation must, in reality, have had a crucial effect on the motion of the tube.

Consideration of magnetic buoyancy may place restrictions on solar dynamics which are rather different to those which have recently been suggested, because the rotation of the Sun has a very strong influence on the mechanism. Fields of 1,000 G might be retained in the middle of the zone for 10 yr or so; deeper down even stronger fields could be retained. If magnetic buoyancy is responsible for bringing to the surface the fields that are observed, their origin must be strong ($\gg$1,000 G) azimuthal fields in the top half of the convection zone. Such fields would make it easier to account for the total flux emerging from the Sun in the course of a solar cycle[3], and would also give the rising flux tubes more resistance to Coriolis twisting, which together with a shorter travel distance to the surface (compared with the full depth of the convection zone) would help keep ψ at a relatively small value.

Possible use of ^{41}Ca for radioactive dating

A LARGE number of cosmogenic isotopes have been suggested for use in radiometric dating[1]. One which has not received much attention is ^{41}Ca (half life $t_{1/2}=1.3\times10^5$ yr (ref. 2)). This is probably due to its small expected concentration in natural samples and the difficulty in detecting its pure electron capture decay. On the other hand, the importance of calcium in many geochemical and biochemical cycles ensures that any method of dating this element would have widespread application. Recent important developments in the detection of radioisotopes using accelerators have motivated us to look at this question. We show here that use of ^{41}Ca as a dating tool may indeed be feasible.

Most proposed cosmogenic dating nuclides are formed by the interaction of cosmic-ray primary and secondary particles with the Earth's atmosphere. The only significant components of the atmosphere which can give rise to ^{41}Ca are krypton and, with low energy α particles, argon. As the abundance of Kr in the atmosphere is only $\sim 10^{-4}\%$, and the effect of α particles small, production by this means is also small. Calcium is, however, a fairly abundant element in the Earth's crust. Here, the reaction ^{40}Ca (n, γ) ^{41}Ca can take place with slow neutrons. At the Earth's surface such a process is favoured both because of a fairly large cross-section ($\sigma = 440$ mb for thermal neutrons), and because the downward moving neutrons in the atmosphere are rapidly thermalised by the ground, giving rise to a significantly enhanced slow neutron flux at the air–surface interface[3].

The concentration of ^{41}Ca after exposure to a flux (f) of neutrons for a time (t) is given by

$$^{41}\mathrm{Ca}/^{40}\mathrm{Ca} = \frac{f\sigma t_{1/2}}{0.693}(1-\exp(-0.693t/t_{1/2}))$$

Using a value of 3×10^{-3} n cm^{-2} s^{-1} for the thermal flux[3], and $t \gg t_{1/2}$, we get a 'saturation' value of $^{41}\mathrm{Ca}/^{40}\mathrm{Ca} \sim 8\times10^{-15}$. This corresponds to an activity of $\sim1\times10^{-3}$ disintegrations per minute per gramme of Ca—about 10^4 times smaller than for contemporary ^{14}C. In addition, the decay of ^{41}Ca takes place by orbital electron capture directly to the ground state of ^{41}K. Therefore, the only radiation given off is the low energy (3.3 keV) X ray from the ^{41}K. It is these factors which have discouraged consideration of this isotope as a dating possibility.

Radioisotope detection with accelerators[4] has the advantage of high sensitivity, independent of the mode of decay. The technique has already been successfully applied[4–8] to measurement of ^{3}H, ^{14}C, ^{10}Be and ^{36}Cl, and shows great promise for some other long-lived isotopes (several variants of this technique are described in ref. 9). To measure a $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ ratio of $\leqslant10^{-14}$, a machine capable of producing a ^{40}Ca beam of $\geqslant10^{13}$ particles per second would be desirable. As each gramme of Ca having the above ratio contains only $\sim10^{8}$ atoms of ^{41}Ca, we would also like to have an overall acceleration efficiency of $\geqslant10^{-5}$. For reasons given below, it might be necessary to accelerate the ^{41}Ca ions to an energy of $\geqslant$300 MeV. There is at least one accelerator in which Ca beams meet the above requirements[10]. Several superconducting or two-stage accelerators proposed or currently under construction should also have such a capability. Also, by including a 'pre-enrichment' step (for example, using an isotope separator), the above intensity requirement could be reduced significantly.

The main interference in such a measurement is expected to come from saturation of the detecting element with a large flux of natural ^{41}K. In this case the technique of absorbing the interfering ion[4] cannot be used because the range of the ^{41}K is greater than for ^{41}Ca. It may be possible to make a sufficiently good chemical separation of the sample to avoid this difficulty. However, an even more elegant technique would be to use the fact that ^{41}K can never have an atomic charge of +20. Thus, by accelerating the ^{41}Ca ions to sufficient energy ($\geqslant$300 MeV) for a significant fraction of them to be fully stripped, they can be magnetically separated from the ^{41}K. We have recently confirmed the feasibility of this technique by separating 200-MeV beams of ^{26}Al and ^{26}Mg at the ALICE accelerator at Orsay (unpublished work). Such a procedure would also be applicable to other isotopes, such as ^{36}Cl, ^{53}Mn and ^{59}Ni, which have nuclear charges greater than an interfering isobar.

To be of optimum use as a dating tool, the production and decay of the radionuclide must be clearly separated in time. With species formed in the atmosphere, this separation is quite natural. For a radionuclide formed in the lithosphere, such a separation means that the material being considered must be removed from (or exposed to) the source of the irradiation flux in a time which is short compared with the relevant half-life. For nuclear active bombarding particles such as neutrons, the shielding required to reduce production to negligible levels is of the order of 500 g cm^{-2}.

Some of the interesting possibilities of using isotopes formed in this way have been discussed by Davis and Schaeffer[11] in connection with ^{36}Cl. For example, one can determine when presently exposed samples were brought to the surface (such as by volcanoes, glaciers, or changing river patterns).

In the case of Ca, a potentially interesting application is the dating of $\mathrm{CaCO_3}$ in sediments. Here the 'age' measured would be the time since the ^{41}Ca was removed from its equilibrium concentration in the overlying water. The most promising environments for such an application are bodies of water (such as lakes) where the Ca residence time is short compared with the ^{41}Ca half-life. In the oceans, the estimated residence time is $\sim10^{6}$ yr (ref. 12). As this is about seven times the ^{41}Ca half-life, the equilibrium ratio of $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ in the oceans is expected to be about two orders of magnitude less than the injection ratio. A $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ ratio of 10^{-16} or smaller would almost certainly necessitate a pre-enrichment step before measurement with an accelerator. In addition, at such low concentrations one must begin to worry about other rare production modes, such as those induced by muon capture or natural radioactivity. However, even here a comparison of the injection ratio of $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ with that found in various parts of the oceans (or sediments) might be useful for studying ocean circulation patterns.

The most exciting application of ^{41}Ca is that it might be used for dating animal (including hominid) remains in the interval of $\sim5\times10^{4}$–10^{6} yr: the bones of most vertebrates consist of calcium phosphate. Most of this Ca comes, directly or indirectly, from plants which have absorbed it from near surface water. The mean rate of erosion on the Earth's surface is estimated to be $\sim$5 cm per 10^{3} yr (ref. 13). Thus, on average, material will rest within 1 m of the surface for $\sim$20,000 yr. Of course, the actual values vary considerably, depending on the location, climate, type of rock and so on (for example, in low relief tropical regions, which may be among the most interesting for this application, the estimated surface residence time can approach 10^{6} yr (ref. 13)). In addition, being readily soluble, there can be exchange between surface Ca and that dissolved from deeper sources. At present we find it difficult to evaluate the overall effect of these factors. Ultimately they can probably only be determined by experiment. However, ignoring the effects of exchange, we estimate that surface water would typically have a $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ ratio of $\sim10^{-15}$. In such a circumstance, ^{41}Ca would offer a possibility for dating in an analogous way to ^{14}C. One could take advantage of the fact that the living sites for early hominids were often grottos having the prerequisite shielding to stop production of ^{41}Ca. Thus the $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ ratio in fossil remains in such sites, compared with the initial ratio, would be a measure of their age. Even if, as is likely, the initial $^{41}\mathrm{Ca}/^{40}\mathrm{Ca}$ ratio were not universally constant, it might be possible to 'calibrate' the technique at various epochs and locations, using dates obtained by other methods.

Although it will take a careful evaluation, and eventually experimental verification of the assumptions made here, we believe that radioactive dating using ^{41}Ca may turn out to be a very important procedure. We are optimistic enough to be currently working on an experimental test of these ideas.

Strontium isotope evidence for petrogenesis of Central American andesites

THE active volcanic belts of Mexico and of Central America can be considered in two groups (Fig. 1). The Mexican volcanic belt (MVB) forms an irregular line trending away from the Middle America Trench, running from Ceboruco and Colima in the west to San Martin on the Caribbean coast[1]. In contrast to the MBV, the active Central American volcanic belt runs some 1,200 km from southern Mexico (Tacaná) and Guatemala to Costa Rica, broadly parallel with the Middle America Trench[1]. With the exception of the alkaline volcano San Martin[2], these are all calc-alkaline andesite volcanoes[1]. Between Mexico and El Salvador, the volcanic chain is built on a crust which includes Precambrian and Lower Palaeozoic crystalline rocks[3,4]. South-east of El Salvador, in Nicaragua and Costa Rica the crust is composed mainly of Cainozoic volcanic and sedimentary rocks resting on Cretaceous ultramafic complexes[3–6]. This change in basement character does not seem to be reflected in the composition of volcanic rocks[7]. Here we report new Sr isotope data for Cainozoic volcanic rocks from Costa Rica, and by comparing these with earlier published data we conclude that all of these volcanic rocks have their origin in the mantle and that a sialic contribution to their origin is insignificant.

Sr isotope data for Cainozoic volcanic rocks from Central America have been published for most of the area shown in Fig. 1. These include data for Mexico[8,9], Guatemala[10,11], El Salvador and Nicaragua[10], and Costa Rica[12]. In addition to the volcanic rocks, Pushkar has reported Sr isotope data for pre-Cainozoic basement rocks from Guatemala and Honduras[10]. For Costa Rica, the only reported Sr isotope data are seven analyses determined by Montigny *et al.*[12]. These include one and four samples respectively from the active volcanoes Irazú and Poás.

We have determined Sr isotope data for 10 Recent lavas and juvenile blocks from the active volcanoes Arenál (four), Poás (four) and Irazú (two). The lavas from Póas are Pleistocene–Recent, whereas those from Arenal were erupted during 1978, and the blocks from Irazú were erupted during 1963–64. Sr isotope ratios were determined on a VG-Micromass 30 mass spectrometer using chemical and mass spectrometric techniques described elsewhere[13]. Measurements of the Eimer and Amend standard SrCO$_3$ carried out during this work yield an overall mean of 0.70812 ± 1. Rb/Sr isotope ratios were determined by a precise X-ray fluorescence technique[14]. The Sr isotope ratios and related analytical data for the Costa Rican lavas are presented in Table 1. Because the analysed samples are all geologically young (<1 Myr, but most are <20 yr), the ^{87}Sr/^{86}Sr ratios presented in Table 1 are taken as initial ratios. These data are shown as a plot of ^{87}Sr/^{86}Sr against ^{87}Rb/^{86}Sr in Fig. 2, which also shows fields of some previously determined Sr isotope data.

Table 1 shows that Sr isotope compositions of Costa Rican lavas from Arenál and Poás show slight but significant internal variation within the range 0.7036–0.7042. The samples from Irazú have ^{87}Sr/^{86}Sr ratios of 0.7036–0.7037. Although there is considerable variation in Rb/Sr (similar to that shown by Mexican lavas) there is no correlation of ^{87}Sr/^{86}Sr with ^{87}Rb/^{86}Sr either for individual sets of data or for the data as a whole. The relatively imprecise Sr isotope ratios of 0.7037–0.7055 reported for Costa Rican lavas by Montigny *et al.*[12] are within the range of Sr isotope data we have reported for the Mexican andesite volcanoes of Nevado de Colima, Colima, and Ceboruco, and the alkali basalt volcano San Martin[9]. Sr isotope values (also determined in the Oxford Isotope Laboratory) for lavas from the Guatemalan volcanoes Santa Maria and Santiaguito are 0.70396 ± 6 (ref. 11) and hence indistinguishable from the values reported above. Earlier Sr isotope ratios determined for lavas from Guatemala, El Salvador and Nicaragua by Pushkar[10] fall within the range 0.7031–0.7049 (13 samples), but are mostly within the range 0.7037–0.7044 (11 samples; see Fig. 2). In contrast, Sr isotope values for pre-Cainozoic metamorphic and igneous rocks from Guatemala, Honduras and Nicaragua are largely within the range 0.71–0.75 (ref. 10).

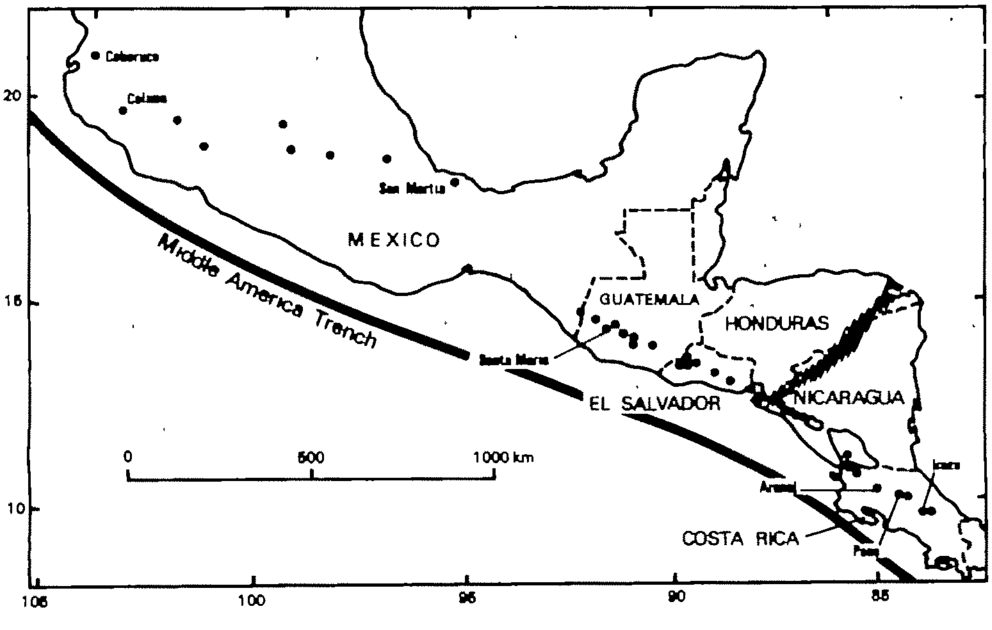

Fig. 1 Volcanoes and plate tectonics of Mexico and Central America. ●, Recently active volcanoes. The shaded area between Honduras and Nicaragua separates an area with older pre-Mesozoic crust to the north-west from an area with continental crust of upper Mesozoic–Cainozoic crust to the south-east. See text for further discussion.

0028–0836/79/0277—0044$01 00

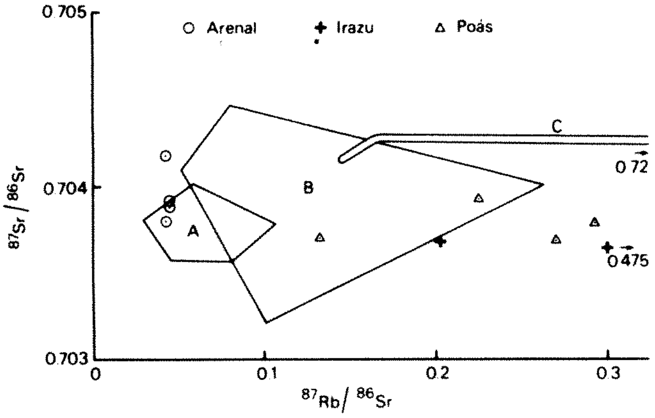

Fig. 2 Plot of $^{87}Sr/^{86}Sr$ against $^{87}Rb/^{86}Sr$ for volcanic rocks from Mexico and Costa Rica. The outlined fields A–C are for volcanic rocks from Mexico (refs 8 and 9). Field A is for lavas from San Martin, B is for lavas from the Colima and Toluca areas and C is for lavas from Ceboruco (see ref. 9, Fig. 2).

The above Sr isotope ratios for volcanic rocks of Mexico and Central America are all within the range reported for lavas from volcanic arcs where sialic crust is absent[10,15–17] and show no significant difference between the MVB and north-west Central America (pre-Cainozoic sialic crust) and south-east Central America (largly Cainozoic sialic crust). The low Sr isotope ratios for Mexican and Central American andesites, commonly within the range 0.7035–0.7040, suggest that sialic bulk contribution to their origin is insignificant.

The Sr isotope data provide clues to the origin and subsequent evolution of andesitic magma. First, the new results confirm that andesites from many oceanic and continental provinces are derived from a source region with $^{87}Sr/^{86}Sr$ ratios within a relatively narrow range of ~0.7035–0.7045 (see refs 9, 18, 19). This range is slightly but significantly higher than the source region of ocean floor basalts (0.702–0.703: ref. 18), and the data could be interpreted in terms of a model, developed from Sr and Nd isotope data, in which andesites are produced by partial melting of mantle wedge which has been enriched in ^{87}Sr as a result of fluids driven off the descending oceanic slab[24,25]. However, the Sr isotope compositions of the andesites lie within the range reported for oceanic and continental alkali basalts[9,18,20–23], and derivation from such a mantle source cannot be excluded[26]. Hence variation in the Sr isotope composition might result from small-scale mantle inhomogeneities. This cannot be evaluated without further Sr and Nd isotope studies, but data reviewed below suggest that some of the small-scale Sr isotope variations might result from processes occurring within the crust rather than the mantle.

The $^{238}U–^{230}Th$ radioactive disequilibrium method has been applied to Costa Rican lavas by Allègre and Condomines[27]. These workers analysed rock and mineral samples from Irazú (six samples, including a 'volcanic bomb' from the 1964 eruption, Poás (two samples) and Arenál (one sample). For the Irazú samples, $^{238}U–^{230}Th$ mineral isochrons indicate crystallisation of the lavas at times between 1.1×10^5 yr and the present day (equivalent to 1964). By considering the evolution of the initial $^{230}Th/^{232}Th$ ratio with time, Allègre and Condomines argue that the Irazú lavas evolved from a magma chamber established at 1.4×10^5 yr BP, with $^{230}Th/^{232}Th = 0.81$. Assuming a similar initial $^{230}Th/^{232}Th$ and source U/Th ratio, the samples from Arenál and Poás must have evolved from independent magmatic systems established respectively at 3.5×10^4 yr and 5×10^4 yr BP. These data may be interpreted as indicating the presence of a magma chamber below each of the three Costa Rican volcanoes. It seems plausible, therefore, that small variations in Sr isotope composition, both within and between volcanoes, are the result of processes (such as selective contamination) which take place within the magma chamber.

Table 1 Analyses of Costa Rican lavas

Calibration of Grenvillian palaeopoles by $^{40}Ar/^{39}Ar$ dating

PALAEOPOLES from the exposed Grenville Province of the Canadian Shield are displaced from those of the remaining shield. It has been proposed that these poles record either a Precambrian plate collision ~1,000 Myr (refs 1–3) or manifest a large rotation and translation of the entire extant North American crust[4–6]. Geological evidence in support of the collisional hypothesis is largely lacking; for example, an acceptable suture zone has not been located. The critical evidence for a choice between the two-plate and one-plate tectonic hypotheses must, therefore, come from dating these palaeopoles because if the magnetisations were acquired contemporaneously with those of the Logan Loop (≈1,000–1,200 Myr), then the two-plate or collisional hypothesis is probably correct. We present here an empirically derived cooling curve for the Haliburton basic intrusions within the Grenville Province. These intrusions are located in a region of high-grade metamorphism, upper amphibolite to granulite facies. Their emplacement times are not known, but in the Haliburton Highlands cooling from the culmination of regional metamorphism, not contemporaneous throughout the Grenville Province, began ~1,050 Myr ago[7]. This is the first cooling curve for an orogen to be derived solely from isotopic data; that is, the first for which both temperature and time have been determined from the same samples. Using this as a calibration curve, we show here that the thermal remanent magnetisation (TRM) components from the Haliburton basic intrusions were acquired between ~980 and 820 Myr ago during slow cooling and that, consequently, the two-plate hypothesis is improbable.

With the rapid extension in recent years of palaeomagnetism to Precambrian rocks in orogenic belts and the subsequent discovery of multicomponent natural remanent magnetisations (NRMs) (see ref. 8 for references), it has become clear that the acquisition times for TRM components are not always directly defined by an isotopic date. In slow cooling conditions, the Rb–Sr whole-rock and K–Ar mineral clocks will record different times. Hence, the TRM acquisition times will be indeterminate. Furthermore, for a history of successive reheating episodes, rather than one of slow cooling, the conventional K–Ar and Rb–Sr dating techniques often lack the requisite discrimination so that partially reset dates will be confused with totally reset dates.

To overcome these limitations, we have applied detailed (15-step) incremental heating, $^{40}Ar/^{39}Ar$ experiments to a variety of minerals, including some types traditionally shunned in K–Ar dating. These minerals were chosen from the same samples studied palaeomagnetically[3] from the Bark Lake and Dudmon dioritic bodies and the Glamorgan gabbro-anorthosite complex in southern Ontario. Using the $^{40}Ar/^{39}Ar$ method as a diffusion experiment, we have calculated Ar closure temperatures for each mineral with Dodson's formula[9], as first suggested by Buchan *et al.*[8]. The required diffusion coefficients were calculated by the method of Fechtig and Kalbitzer[10]. These closure temperatures are insensitive to uncertainties in the assumed cooling rate[9] and so the formula can most profitably be applied to Precambrian orogenic belts where a slow cooling following uplift and erosion is likely to have occurred. By thus establishing a cooling curve from isotopic studies, we can directly date TRMs using their empirical blocking temperatures.

In detailed palaeomagnetic studies[3,8], the Haliburton intrusions have yielded three NRM components, two of which are probably partial TRMs (PTRM) and sometimes occur within the same specimen. The component with the highest laboratory blocking temperature gives a palaeopole, Hb_1, at the southern limit of the Grenvillian poles and near southeastern Australia, and the second PTRM component has a pole, Hb_3, at the northern limit (Fig. 2). The inferred direction of apparent polar wander (APW) is from south to north[1–3]. As a reasonable approximation in this first attempt at the direct dating of multicomponent TRMs from orogenic belts, we used field blocking temperatures estimated by the conventional static temperature method[8,11,12] rather than the kinetic temperature approach developed by York[13,14] that is formally analogous to the approach used here with isotopic closure temperatures. From the theoretical curves of Pullaiah and others[11], we estimate that the bulk of the Hb_1 PTRM component carried by magnetite was acquired in the range 520–570 °C and that the bulk of the Hb_1 component carried by hematite, if PTRM, was acquired in the range 600–650 °C. We thus assign a probable maximum acquisition range for the Hb_1 component of 520–650 °C by the static method. Similarly, field temperatures of not more than 250 °C could explain the laboratory blocking temperatures up to 450 °C for the Hb_3 PTRM carried by a titanomagnetite. We thus have an ideal situation for dating, having rocks with PTRMs acquired ~300 °C apart and with palaeopoles about 60° apart latitudinally straddling the entire group of Grenvillian palaeopoles.

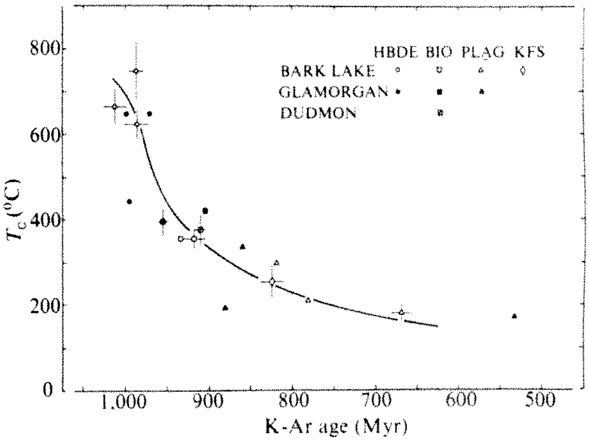

Fig. 1 An isotopically derived cooling curve for the Haliburton area using revised decay constants[16]. A cooling rate of 5° Myr^{-1} was assumed in Dodson's formula for all but the three rightmost points, for which 0.5° Myr^{-1} was chosen. The error bars are 1σ.

We have dated six hornblendes, five relatively coarse biotites, six plagioclases and one potassium feldspar. Experimental details will be described elsewhere. All of the biotites and four of the hornblendes as well as the K-feldspar gave excellent plateaus over at least 90% of the released Ar. There were also significant age differences among the biotites, even from the same intrusions, and between the biotites and hornblendes. These remarkable facts can best be interpreted as due to a slow-cooling history and are least compatible with a history comprised of a sequence of episodic thermal events. Such events cannot partially reset coarse biotites and the sensitive K-feldspar without leaving anomalous and irregular age spectra[15]. One of the interesting discoveries in this project was that plutonic plagioclases, previously considered unreliable K–Ar clocks, yield plateau segments in the laboratory temperature range of ≈700–900 °C and that these plateaus have chronological significance. Specifically, in the only sample with coexisting K-feldspar and plagioclase, the plateaus for these minerals are concordant. In calculating the diffusion coefficients for plagioclases, we have treated the Ar corresponding to the plateau segments as an independent phase. We used two conservative criteria to classify Ar closure temperatures as reliable or unreliable. First, a plateau consisting of at least five consecutive gas fractions must exist. Second, the diffusion coefficients corresponding to at least these five steps must lie on a statistically well defined straight line in an Arrhenius diagram.

The overall pattern of closure temperatures shown in Fig. 1 is internally consistent with a slow cooling interpretation and the

0028–0836/79/0277—0046$01.00

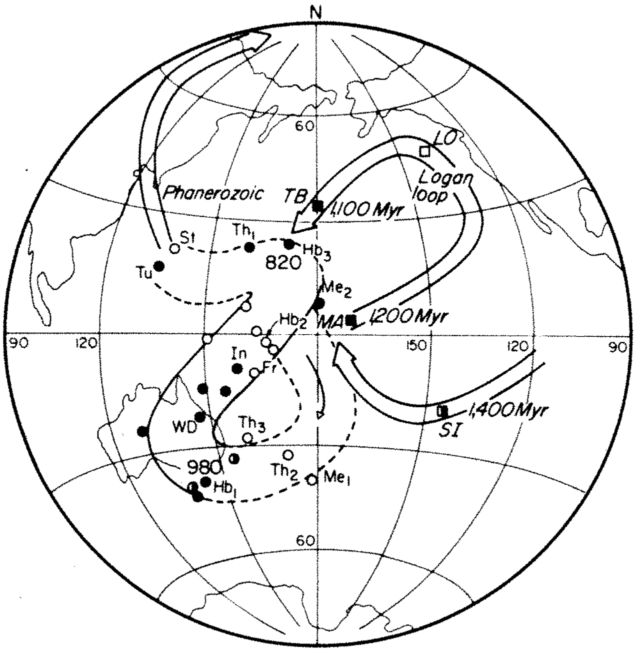

Fig. 2 A proposed Grenville Loop APW path. The calibrated part (solid) corresponds to a minimum average drift rate of 5 cm yr^{-1}. The symbols and identity of unlabelled poles are given elsewhere[3,17].

temperatures are geologically reasonable. For example, those for the hornblendes are less than the expected maximum temperatures ($\simeq$700 °C) during the peak of metamorphism in this area[18]. Therefore, with this cooling curve, we assigned acquisition times of 980 ± 10 Myr (520–650 °C) for component Hb_1 and $\lesssim$820 Myr ($\lesssim$250 °C) for Hb_3. In this way, we have calibrated the APW path for many of the Grenvillian palaeopoles.

All of the known reliable Grenvillian palaeopoles are plotted in Fig. 2 as well as poles for the Tudor gabbro (Tu) and Steel Mountain anorthosite (St) which occur within the Grenville Province. Superimposed is our proposed Grenville Loop with the calibrated track bounded by solid lines.

Although the shape, position and sense of direction of this loop have already been proposed[19,20], the new time limits significantly alter the previous tectonic interpretations. Our calibrated track represents a minimum average drift rate of $\simeq$5 cm yr^{-1}, certainly more reasonable than the rates of 10–20 cm yr^{-1} deduced from some previous tectonic interpretations[19–21]. Earlier proposed Grenville Loops that lap back on themselves[21,22] have used very approximate and indirect age assignments and should be viewed as first approximations to more refined definitions of APW paths based on direct dating procedures such as that outlined here. We must reject the two-plate hypothesis because the ages assigned to our calibrated track are much younger than required by that hypothesis ($\simeq$1,000 Myr north of the Equator on the northwards segment).

There is support for this calibration from other dating studies. Reynolds[23] has assigned a $\simeq$910 Myr date to the Frontenac Axis dikes (Fr) pole, previously thought to be $\simeq$690 Myr. Dallmeyer[24] has placed the Indian Head (In) pole at $\simeq$900 Myr. Dallmeyer and Sutter[25] assigned a date of 980–1,010 Myr to the Whitestone diorite (WD) pole. Although the confidence ovals for the Hb_1 and WD poles overlap slightly, by interpolation in Fig. 2, the WD magnetisation has probably been acquired in the 900–980 Myr interval. The main cause of the apparent discrepancy between this acquisition time and that suggested by Dallmeyer and Sutter is their choice of a much lower closure temperature (500–550 °C) for their hornblende (see ref. 26). We think such estimates from the literature are only first approximations (they ignore sample differences, for example) and may yield only lower limits to this temperature.

The dashed, southwards track is uncalibrated but does contain poles of probable age 1,000–1,100 Myr such as the Cardenas Lavas and Pikes Peak Granite poles[21] those from the Jacobsville sedimentary formation[20] as well as those of the Nonsuch shale and the Freda sandstone[27]. Pole Me_1 from the Mealy Mountain anorthosite[4] and poles Th_3 and Th_2 from the Thanet gabbro in the Hastings Basin[17], if TRM components, are predicted from Fig. 2 to have acquisition times of $\simeq$980–1,020 Myr. The dashed segment between Hb_3 and Tu is entirely speculative because no reliable date can be assigned to Tu or St. Although the palaeomagnetic literature often quotes a 680 Myr date[28] for Tu, the original authors[28] emphasised their uncertainty concerning the event represented by this date. A further complication is the presence of North American Cambrian poles within a swath roughly from Tu to Fr[21,29]. We are therefore unsure how an APW path should be constructed after Hb_3.

We reject the Hadrynian Track of Morris and Roy[19] and the Hadrynian Loop of Irving and McGlynn[21] because not only are the dates of some of their critical rock units very suspect (Tudor gabbro, Franklin diabase and Aillik dikes) or incorrect (Frontenac Axis dikes), but also the time of acquisition of the Stoer Group magnetisation may be quite different from the precise 970 Myr (new decay constant) Rb–Sr date. Rb–Sr dates on sedimentary rocks are ambiguous[30,31].

In conclusion, through the exploitation of the $^{40}Ar/^{39}Ar$ incremental heating technique as both a diffusion experiment and a method of dating, we have calculated a cooling curve for the Haliburton intrusions and thereby have calibrated the northward track of a proposed Grenville Loop. The assigned dates are incompatible with the collisional or two-plate hypothesis as an explanation of the displaced Grenvillian palaeopoles. This is not to say that such a collision did not occur or did not influence the so-called Grenville Orogeny but rather that it has not been recorded palaeomagnetically. What is recorded is a translation and rotation of Grenvillia and Interior Laurentia[21]. The role of any such collisional process is likely to have been similar to that proposed by Dewey and Burke[32] with a collisional zone south-east of the Grenville Province and now hidden under the Appalachians.

We thank Drs D. C. Green and K. L. Buchan for helpful discussions, also Peter Kuybida and W. J. Kenyon for technical assistance. The work was supported by the NRC of Canada through a Research Operating Grant (D.Y.) and a Negotiated Development Grant.

Pore water sampling in anoxic carbonate sediments: oxidation artefacts

ANY exposure of anoxic estuarine sediments to the atmosphere during sample handling and processing can lead to decreased values of ferrous iron[1], reactive phosphate[2] and reactive silicate[3] in the pore waters of these sediments. Thus, the mishandling of anaerobic sediments and their pore fluids will in turn lower calculated diffusional fluxes of these compounds from the sediments into the overlying water. To date, this oxidation effect has only been documented for clastic sediments rich in iron. We present data here which indicate that a similar phenomenon occurs when anoxic iron-poor, carbonate-rich sediments are exposed to an oxidising milieu.

A core was taken during June 1978 from a shallow water sub-tidal area in Coot Bay on the northeastern shore of Bermuda. Previous data[4,5] collected in the summer of 1977 indicated that the sediments were anoxic and alkalinity and nutrient regeneration was occurring. The core was obtained by hand by carefully pushing a 6.6 cm i.d. polycarbonate core liner into the sediment.

On retrieval, the core was placed into a polyvinyl chloride core carrier, purged with nitrogen and returned to the Bermuda Biological Station for Research. The time between the taking of the sediment sample and the initiation of the pore water extraction in a nitrogen-filled glove bag was ~15 min.

The core was extruded in the glove bag under nitrogen and sectioned into six 10-cm segments. While in the glove bag, the core sections were cut in half vertically using a Teflon coated spatula. One half of the six core sections was placed into a 500 ml linear polyethylene (LPE) centrifuge bottle which had been previously cleaned for trace metal analysis[6]. The bottles were centrifuged at 10,600*g* at exactly *in situ* surface sediment temperatures under nitrogen.

This set of centrifuged samples was placed back in the nitrogen-purged glove bag and filtered through precleaned 0.4-μm Nuclepore filters[3]. The filtered samples (10 ml) were then pipetted into a 60-ml conventional polyethylene (CPE) bottle and within 30 min were analysed for *p*H and titration alkalinity. The titrated sample was later analysed for sulphate, calcium, phosphate and reactive silicate. The remainder of the filtered sample was decanted into a 60-ml CPE bottle which had been cleaned as described by Patterson and Settle[6] and immediately acidified to 1% with concentrated Ultrex nitric acid for later trace metal analysis.

The other set of samples was processed in a similar manner except for two important differences: (1) the samples were removed from the N_2 atmosphere and exposed to the atmosphere of the laboratory for 10 min before being placed in the centrifuge bottles; (2) the filtration and pipetting steps were carried out in the laboratory atmosphere instead of in the glove bag. The filtering and pipetting of the supernatant pore water took ~5 min for each sample and while one sample was being processed the others were kept in the glove bag under nitrogen. Therefore the maximum atmospheric exposure for each sample was 75 min.

Phosphate analyses were run on a Technicon Auto Analyzer II system[7] after a 2 : 1 dilution. The differences between duplicate dilutions never exceeded 2%. Reactive silicate was analysed using the method of Strickland and Parsons[8] modified for pore water by Presley[9]. Replicate analyses indicate a standard deviation of $\pm 1\ \mu\mathrm{M\ l^{-1}}$. Total reactive iron was analysed colorimetrically[10] using the Technicon Auto Analyzer II system[11] with a coefficient of variation of $< \pm 0.05\ \mu\mathrm{M\ l^{-1}}$. The samples were never frozen and all the analyses were carried out within 5 weeks of sample collection.

We found that there was a decrease of Fe of 81% in the top 25 cm of the core when the samples were exposed to laboratory air compared with the subsamples processed under nitrogen (Fig. 1). These two sections have iron concentrations $>1.80\ \mu\mathrm{M}$ ($100\ \mu\mathrm{g\ l^{-1}}$). Below this concentration the dissolved iron is apparently not affected by the atmospheric exposure. The dissolved phosphate data parallel the iron in that the greatest differences between the nitrogen processed samples and those exposed to the laboratory atmosphere are in the two uppermost core sections (Fig. 1). There is also a significant decrease in the PO_4^{3-} concentration in the lowest core section where the iron concentration is little affected. The reactive silicate values, with the exception of the 35-cm depth sample, are all lower in the laboratory exposed samples. There were no significant differences in the concentrations of *p*H, SO_4^{2-}, Ca^{2+}, Mn^{2+} and titration alkalinity between the nitrogen processed and the laboratory exposed subsamples.

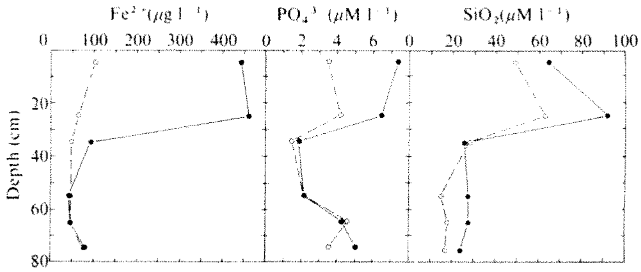

Fig. 1 Pore water concentrations of ferrous iron (Fe^{2+}), phosphate (PO_4^{3-}) and silicate (SiO_2) for a core from Coot Bay, Bermuda. ○, Samples processed after atmospheric exposure; ●, samples processed under N_2.

It seems that there is a critical dissolved iron value where laboratory exposures of as long as 75 min has no effect on the total dissolved iron concentration in the pore waters. Below this critical iron concentration, phosphate is also little affected by the presence of oxygen. The oxidation of Fe^{2+} to Fe^{3+} is very rapid at neutral *p*H (refs 12, 13). Whether this dissolved iron is in a physicochemical state that is unaffected by the increased partial pressure of oxygen is unknown. The iron may be associated with dissolved organic matter[14] (DOM) and the kinetics of its oxidation may be much slower than that of ionic Fe (ref. 15). It is interesting that pore water iron data collected before the knowledge of oxidation effects tend to show 'residual' dissolved iron values close to $100\ \mu\mathrm{g\ l^{-1}}$ (refs 16, 17).

Reactive silicate, however, is continually lost by laboratory atmospheric exposure even when the dissolved iron is apparently not being oxidised. These data indicate that the mechanism of silicate removal may not be directly related to the oxidation of Fe^{2+}. It is not known what governs the loss of silicate during oxidative handling and processing, nor whether the removal of SiO_2 without the oxidation of Fe^{2+} occurs only in calcareous sediment.

The data from the top 25 cm of core indicate that for every $10\ \mu\mathrm{M}$ of iron removed during oxidation $4.5\ \mu\mathrm{M}$ of phosphate is lost. More phosphate per mol of iron is lost in these calcareous sediments than from the anoxic clastic sediments studied by Loder *et al.*[3]. This may be related to the exposure time of the pore water sample to the oxygen atmosphere rather than the effective scavenging potential of the iron hydroxide formed. The iron-rich clastic sediments of Loder *et al.*[3] were only exposed for a period of 12 min. The Coot Bay data indicate

0028–0836/79/0277—0048$01.00

that an average of 28% of the reactive silicate is lost during the conditions of the experiment. This is double that found by Loder *et al.*[3] for clastic sediments.

Our experiments and those of Bray *et al.*[2], Troup *et al.*[1] and Loder *et al.*[3] emphasise the importance of proper sample handling if meaningful nutrient data from anoxic pore waters are to be obtained. Our data indicate that decreases of phosphate and reactive silicate in pore waters from anoxic carbonate-rich sediments do occur unless proper care is taken to ensure the lack of atmospheric exposure. Because pore water data are of extreme importance in understanding diagenetic pathways in marine sediments,[18,19], and pore water exchange with overlying water may be extremely important in the fluxes of nutrients and trace metals,[20-22], the collection of pore waters from reducing sediments must be accomplished with great care, if valid geochemical models are to be produced.

We thank K. Wilson and M. E. Hines for technical assistance, and T. C. Loder for encouragement. This work was supported by NSF grants OCE77-20484 and PCM77-12624, and the UNH Hubbard Marine Fund.

A pre-2,000 Myr old granulite facies metamorphosed evaporite from Caraiba, Brazil?

THE identification of the first occurrence on Earth of sediments of evaporitic origin formed from seawater is obviously important not only for the study of the chemical evolution of ocean water but also in understanding the development of common sedimentary rock assemblages and the stabilisation of cratons. Until recently[1,2] confirmed pre-2,000 Myr old evaporites were unknown and indeed Ronov[3] maintained that they did not exist. Pyroxene granulite facies metamorphosed evaporites are also extremely rare[1,4] and thus a pre-2,000 Myr old example is important. We give here a brief account of the mineralogy of some of the rocks found in the Caraiba mine area of Brazil which suggests that evaporites existed earlier than previously recognised and were associated with dolomitic rocks.

The Caraiba copper deposit of Brazil is in the north of the state of Bahia, 9°52′ S, 39°52′ W (Fig. 1) being rich in chalcopyrite and bornite and is associated with a sequence of high grade gneisses, pyroxene granulites, migmatites and possible meta-evaporites which together form the Caraiba supergroup, set in the eastern margin of the Sao Francisco craton. Granite gneisses which cut these high grade rocks are about 2,050 ± 70 Myr by Rb–Sr age determination, corresponding to the Transamazonian orogeny, so that the earlier rocks are older than this date and some charnockitic types in the Caraiba area have Rb–Sr ages of 2,900 Myr so that the metasediments could well be Archaean.

The predominant rock type in the Caraiba mine area is enderbitic charnockite with biotite and this encloses the calc silicate proposed meta-evaporites but other rocks, such as granite gneisses, basic and ultrabasic granulites and pegmatoids come into contact with the possible meta-evaporites which are predominantly calc silicate diopsidites. Subordinate diopside–forsterite marbles, anhydrite–diopside ± K feldspar granulites also occur. Dolomite has not been identified in the carbonate bearing rocks. Only the diopsidites outcrop, the anhydrite-bearing rocks being obtained from drill-cores. Scapolite is present in some samples. The principal host rock for the chalcopyrite–bornite mineralisation is hypersthenite, and the mineralisation is thought to be magmatic, but the calc silicate rocks in contact with mineralised ultramafic or mafic rocks usually have some mineralisation. The occurrence of xenoliths of diopsidites in the hypersthenite confirms the older age of the diopsidites.

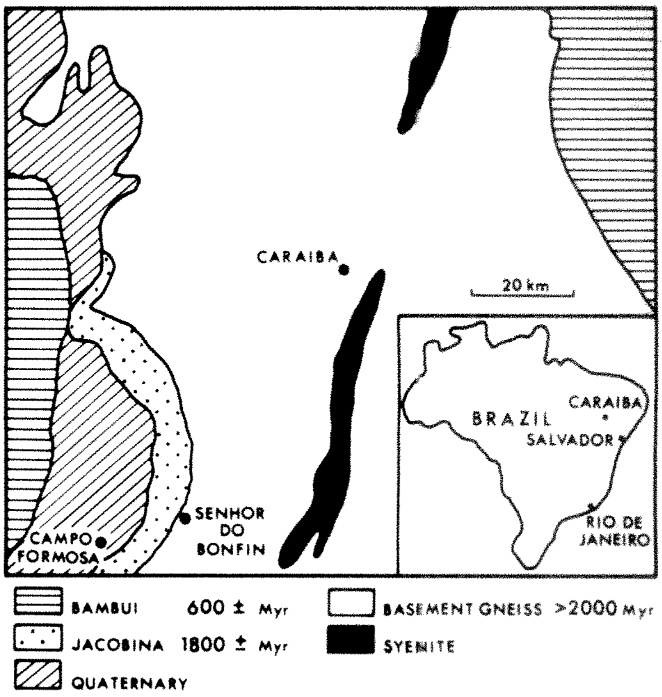

Fig. 1 Geological sketch map of the Caraiba area.

Samples range from the principal assemblage which is pure diopsidite, sometimes with green spinel, accessory apatite and sphene through dominantly two phase diopside—anhydrite rocks with variable amounts of phlogopitic mica, olivine (forsterite), microcline, sphene and grossular garnet to samples rich in calcite. Sometimes diopsidite grades into plagioclase and sphene bearing rocks.

A coarse (3–5 mm) granular specimen with 51.6% diopside, 47.5% anhydrite and 0.9% phlogopitic mica contains nearly colourless diopside ($2V_\gamma$ 55½; $Z \wedge \gamma$ 41 ± 1°) with an unzoned composition of 54.10% SiO_2, 1.79% Al_2O_3, 16.74% MgO, 24.18% CaO and 2.07% FeO (all Fe calculated as FeO), total 99.51% determined by electron microprobe analysis using energy dispersion. This is a composition close to pure diopside with $Ca_{0.97}(Mg_{0.91}Fe_{0.06}Al_{0.05})_{1.02}Si_{1.97}Al_{0.03}O_6$, and contains

0028–0836/79/0277—0049$01.00

the low Al typical of many metamorphosed calc silicate rocks. The anhydrite (2V_γ 42°) has excellent cleavages and repeated lamellar twinning, and does not contain more than a trace of Sr. Such a rock, with only about 1% Al_2O_3 was clearly originally almost free of any clay or aluminosilicate minerals and was probably largely gypsum or anhydrite with diagenetic or detrital silica and perhaps a trace of illite. At one horizon olivine–anhydrite diopside samples occur with Fo_{94}.

Other samples are finer grained and contain grey, non-perthitic microcline which probe analysis shows to be nearly pure $KAlSi_3O_8$, accessory sphene containing ~1.5% Al_2O_3, accessory pyrite and diopside with similar low Al_2O_3 (1.73%) to the above but with more TiO_2 (0.35%) and FeO (5.20%). The extreme end-member contains no anhydrite and is a fassaite–calcite–phlogopitic mica (mol Fe/(Fe+Mg) = 0.21) assemblage that clearly contained much original aluminosilicate, presumably at least in part illite. the pyroxene in such samples varies in composition but 49.4% SiO_2, 5.8% Al_2O_3, 0.4% TiO_2, 13.2% MgO, 5.1% FeO (total), 0.5% MnO, 24.4% CaO is typical, giving $Ca_{0.98}(Mg_{0.74}Fe_{0.16}Mn_{0.01}Ti_{0.01}Al_{0.11})_{1.03}Si_{1.85}Al_{0.15}O_6$. This clearly reflects both the higher Al content of this rock, which is demonstrated by the quantity of mica (10%) and its Al_2O_3 content (16%), and the high grade of metamorphism that facilitated the incorporation of substantial Al in the pyroxene. This assemblage clearly arises from an impure siliceous or silicified dolomite. In view of the predominance of diopsidite the commonest original sediment was presumably dolomite.

Other samples near the calcite–pyroxene rich assemblages contain a highly altered unidentified sheet-like mineral containing about 38% SiO_2, 20% Al_2O_3, 24% CaO with 4% MgO + FeO, and now partly replaced by calcite and small (0.04 mm diameter) euhedral nearly pure grossular garnet of average composition 40.02% SiO_2, 22.14% Al_2O_3, 37.57% CaO, 0.75% MnO and less than 0.20% FeO and MgO with a slightly MnO enriched margin (0.91%) compared with the core (0.57%). Other grains of this highly altered mineral are replaced by clinozoisite.

These preliminary results, obtained with an electron microprobe, are under further investigation, but they may support the recent indications[1,4] that evaporites existed earlier than previously generally recognised[3] and were associated with dolomitic rocks, a common association in most younger evaporite deposits. However, it is possible that the anhydrite could have formed from dolomite by SO_2 attack, the SO_2 being derived from oxidation of chalcopyrite to bornite and magnetite during the metamorphism, for some magnetite is ubiquitous. Post metamorphic oxidation is notably lacking and fresh sulphides occur in outcrops. Accordingly, the evaporitic origin is not certain.

Any original halite would obviously have migrated from such a high grade metamorphic position but if the deposit was originally a sabhka-type evaporite there may not have been very much halite. The olivine, spinel and calcite would be derived from dolomite breakdown in well-known reactions.

The electron microprobe was funded by the University of Glasgow.

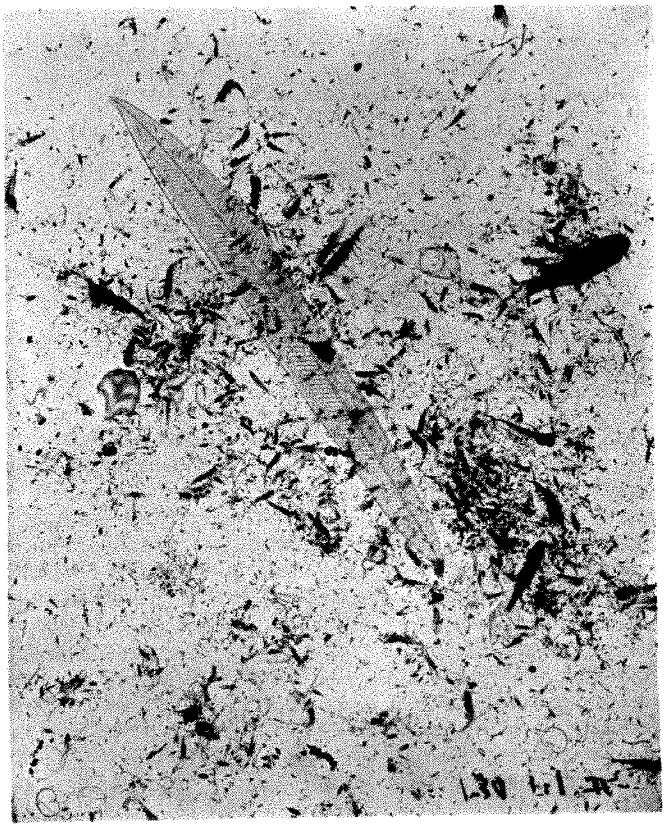
Silhouette photography of oceanic zooplankton

NO adequate method has been available to characterise a sample of zooplankton quickly and accurately. As Mullen noted[1], although relatively rapid, measures of standing crop such as displacement volume, dry weight, carbon content and electronic size spectra do not distinguish clearly between animals and plant or detrital material, much less between herbivores and carnivores. Direct microscopic enumeration has remained the only approach giving information detailed enough for many ecological studies. Unfortunately, this method is time-consuming, it cannot be undertaken routinely at sea, and it is feasible only after chemical agents have been added to 'fix' and then 'preserve' the sample. With time, plankton samples always deteriorate in preservatives, although the degree of this effect varies with species. We report here that a little-known photographic technique—high-speed silhouette photography[2,3]—can be used to analyse live zooplankton samples at sea.

The photographic system we used consisted of 8 × 10 inch Eastman fine-grain positive film 7302, an electronic flash with a xenon bulb (E.G. & G., Inc., FX6A) and a pulse duration of 3×10^{-6} s, and a plastic tray. Lamp-to-film distance was ~1.0 m. Immediately after collection, whole samples or aliquots of particularly dense samples were poured to a depth of about 1 cm into the plastic tray directly on top of the film. A glass plate was used to seal the top of the tray when seas were rough. One flash in a darkened room exposed the film. Samples were then preserved in the usual fashion (8% buffered formalin, pH ~8.2). Because of the shortness of the flash, action was stopped and results were unaffected by the motion of the ship or the subjects. Essentially any container and any powerful electronic flash could be used. The latter should be arranged to approximate a point-source as closely as possible. We housed the small-diameter xenon bulb in a non-reflective tube.

Fig. 1 Actual-size silhouette of a live zooplankton sample collected in the Sargasso Sea.



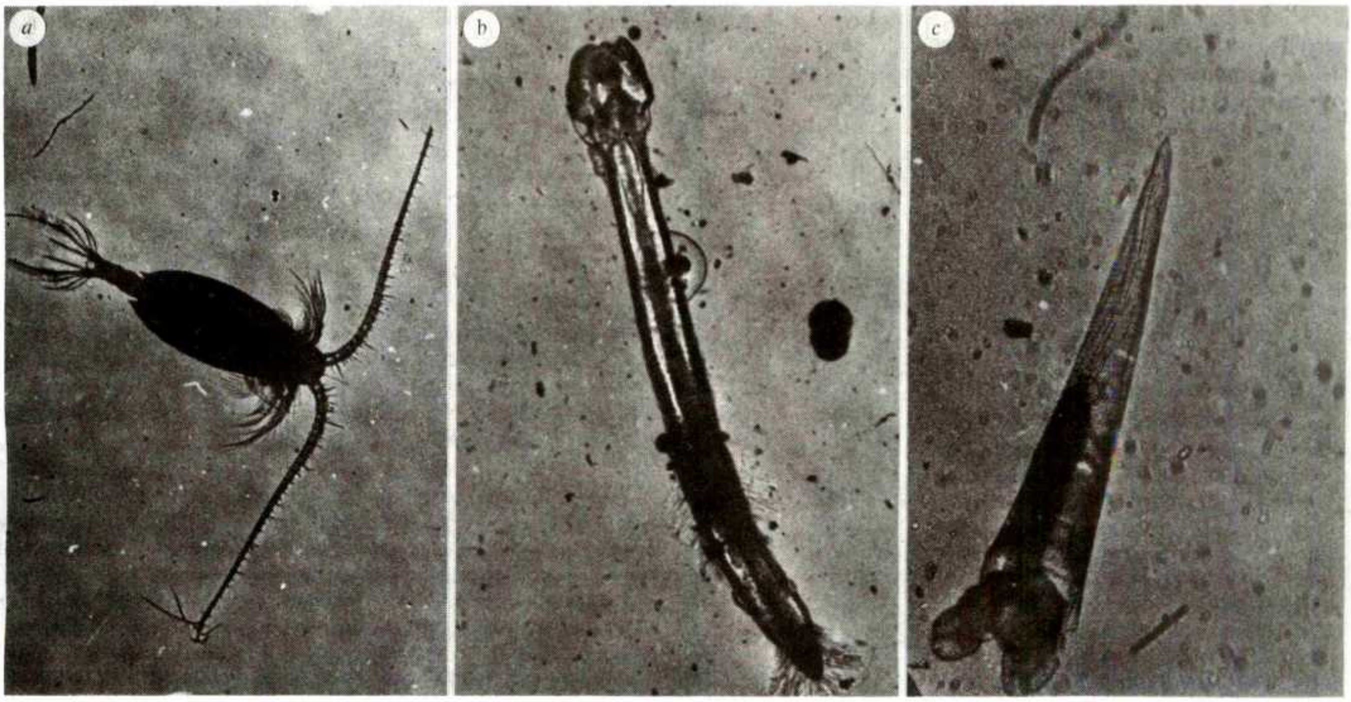


Fig. 2*a* Enlarged silhouette of a copepod, *Undinula vulgaris* female, ~2.5 mm. *b*, Enlarged silhouette of a chaetognath, *Pterosagitta draco* ~8 m. A fish egg lies just beyond the body trunk. *c*, Enlarged silhouette of a shelled pteropod, *Styliola subula*, ~2 mm.

Figure 1 is the contact print of a negative produced as described above. The sample was collected between 0 and 89 m depth in the southern Sargasso Sea in February 1978 and represents 443 m^3 of seawater filtered through the 0.333-mm mesh of a MOCNESS net system[4]. The relatively large leaf-like animal is an eel larva at the leptocephalus stage.

Such negatives were generally examined at sea by placing them between two glass plates and counting random transects but, also, we have projected them on a viewing screen. To be enumerated in a negative, the density of organisms first would be considerably reduced by subsampling. Because the area of a negative corresponds to a known volume of ocean, it can be used to characterise quantitatively the plankton of a region if resolution were sufficient.

The resolution obtained by our optic-less imaging technique was more than adequate for this purpose. It was possible to make generic and, occasionally, specific identifications of specimens in many cases. Figure 2*a–c* shows enlargements of individual animals from actual-size negatives such as Fig. 1. The animals were alive when they were photographed. The copepod in Fig. 2*a* was moving rapidly and erratically. The chaetognath in Fig. 2*b* is easily identified even though the collarette is nearly gone, as frequently occurs in net collections. The pteropod mollusc in Fig. 2*c* has its wing-like flaps partly extended in their swimming position. The tissue of a preserved specimen typically would have contracted into an indistinguishable lump. A negative such as Fig. 1 could not have been obtained by conventional photographic or photomicrographic techniques, which do not give the breadth of the field of view and the depth of focus required to accommodate the entire sample, nor the high resolution we obtained despite ship and animal motion.

The rapidity, ease, and low cost of silhouette photography of plankton make it potentially useful to field workers with limited facilities. It can produce a permanent record of a live sample, which is unobtainable at present by any other means. Most important, the technique is non-destructive. Preservatives can be added after the image is recorded, and the sample can be sorted and examined on shore.

An *in situ* silhouette camera system designed to assess zooplankton patchiness has already been tested and a programme has been initiated to fully automate enumeration of our negatives by means of computer image-analysis techniques.

We thank Dr H. Michel for help in identifying species and Andrew Ramsey for technical advice.

Drinking behaviour induced by intracerebroventricular administration of enkephalins to rats

INTRACRANIAL administration of substance P to rats inhibits drinking induced by water deprivation, sodium-chloride load, and intracerebroventricular (i.c.) injection of angiotensin II or carbachol[1]. It has been suggested that substance P is a neurotransmitter used in primary afferent fibres terminating in the spinal cord[2–4], but recent findings suggest also that, at least in mice, substance P may release endogenous opioids and thus produce analgesia[5]. If cerebral effects of substance P are, at least in part, due to the release of endogenous opioids, these substances might also possess an antidipsogenic effect. We describe here experiments in which we observed that enkephalins administered into the lateral ventricles of rats inhibited drinking induced by water deprivation or by i.c. injection of angiotensin II. We thus provide evidence that enkephalins have a potent and reproducible antidipsogenic effect in the rat.

In a preliminary operation, i.c. cannulae (o.d. 0.6 mm) were implanted stereotaxically in male Wistar rats. The animals weighed 250–300 g and were under Equithesin anaesthesia (3 ml per kg). They were allowed at least 10 d before testing began. Injections were made in conscious rats through a stainless-steel injector (o.d. 0.3 mm) temporarily inserted into the guide cannula. The drugs were dissolved in Tyrode solution and injected in volumes of 1 μl. Drinking was induced by a 16-h period of water deprivation or i.c. injection of angiotensin II, 100 ng per rat. The drugs used were angiotensin II (AII, synthetic 5-isoleucine-angiotensin II; Calbiochem), (Leu^5)-enkephalin (LEN), (Met^5)-enkephalin (MEN) and (D-Ala^2, D-Leu^5)-enkephalin (AEN) (all Wellcome).

In AII-treated rats, LEN and MEN inhibited drinking, but the effect required large amounts of peptide (100–200 μg per rat). Drinking inhibition was apparently dose dependent (Fig. 1*a*, *b*) and, as indicated in Fig. 1*d*, when latency between drug injection and the beginning of water intake was recorded, a clear-cut inhibition was also seen at relatively low doses (25–50 μg per rat).

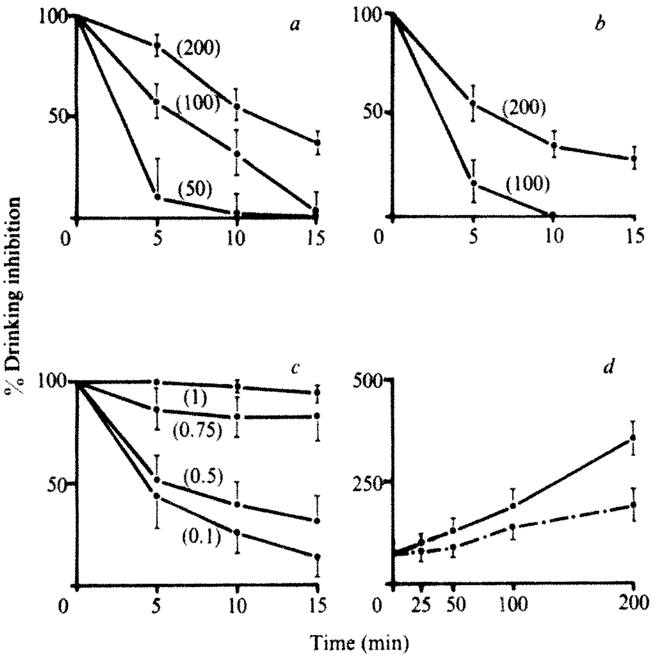

Fig. 1 Angiotensin II-treated rats. Inhibitory effect of (Met^5)-enkephalin (*a*), (Leu^5)-enkephalin (*b*) or (D-Ala^2, D-Leu^5)-enkephalin (*c*) on water intake induced by i.c. injection of angiotensin II, 100 ng per rat. In parentheses, doses in μg. Latency time after i.c. administration of (Leu^5)-enkephalin (continuous lines) or (Met^5)-enkephalin (dotted lines) is shown in *d*. Points and vertical bars represent means ± s.e. of 6–8 experiments.

AEN was about 2,000–4,000 times as active as the naturally occurring enkephalins LEN and MEN. In fact, a complete inhibition was attained with 1 μg of AEN (Fig. 1*c*), whereas 0.5 μg of the peptide had almost the same inhibitory effect as 100 μg LEN and 200 μg MEN.

In water-deprived rats, LEN and MEN inhibited water intake (Fig. 2*a*). The effect was short lasting and, again, required large amounts of peptide (200 μg per rat). As before, AEN was more effective than LEN and MEN: 10 μg completely inhibited drinking for more than 60 min, and a clear-cut inhibitory effect, lasting more than 30 min, was elicited by doses as low as 100 ng (Fig. 2*b*). Lower doses (10 ng) were still effective, but difference from controls was not statistically significant.

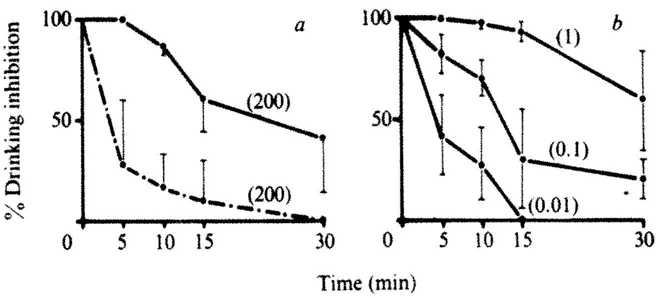

Fig. 2 Water-deprived rats. Inhibitory effects of (Leu^5)-enkephalin (*a*, continuous lines), (Met^5)-enkephalin (*a*, dotted lines) or (D-Ala^2, D-Leu^5)-enkephalin (*b*) on water intake induced by a 16-h period of water deprivation. In parentheses, doses in μg. Points and vertical bars are means ± s.e. of 6–8 experiments.

In both kinds of experiments, animals which received LEN or MEN, 200 μg per rat, were immobile and did not react promptly to tactile and acoustic stimuli. This 'depressive' effect lasted about 5 min and disappeared before the antidipsogenic effect. Rats which received these substances at relatively low doses (25–50 μg) as well as AEN at doses of 1 μg or less did not react in this way. At these dose levels, enkephalins did not produce any nonspecific behavioural modification or modify food intake in rats trained to eat their daily allowance of food during a 2-h period, between 2100 and 2300 (Fig. 3). Naloxone, 2,000 μg per kg, subcutaneously, reduced but did not completely abolish the antidipsogenic effect of the peptides.

The present data provide evidence that i.c. administration of enkephalins elicits in the rat an antidipsogenic effect which is potent, reproducible and dose dependent. This effect might be considered specific and not simply due to the depressive activity of enkephalins. In fact, it was evoked even by doses which did not affect the rats' nonspecific behaviour, as in the case of AEN, which was effective at doses as low as 10 ng, and was still evident after the 'depressive' response had disappeared, as in the case of LEN, 200 μg, which, in water-deprived rats, significantly inhibited drinking for more than 30 min. Moreover, water intake, but not food intake, was modified by the peptides.

The different potency of the naturally occurring enkephalins, on the one hand, and AEN, on the other, may be accounted for by the different sensitivity of the latter to enzymatic hydrolysis, as a consequence of replacing Gly_2 by D-alanine[6].

The results of these experiments, although confirming our working hypothesis, give us no conclusive indication of whether substance P inhibits drinking by means of enkephalin release, nor any indication of the possible physiological significance of the antidipsogenic effect of enkephalins.

Thirst is an unpleasant sensation which may be so severe as to be regarded as a suffering and, in a wide sense, as pain. Thus, it is

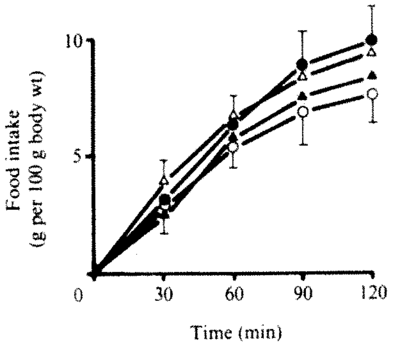

Fig. 3 Food intake in rats trained to eat their daily allowance of food during a 2-h period, between 2100 and 2300 (ref. 1). Controls (▲) received 1 μl of Tyrode solution, i.c.; treated rats received 1 μl of Tyrode solution containing fully antidipsogenic doses of LEN (●, 200 μg), MEN (○, 200 μg) or AEN (△, 1 μg). Points and vertical bars are means ± s.e. of 5–7 experiments.

not entirely impossible that the analgesic effect of enkephalins may be involved in the mechanism(s) of water intake control. However, the fact that the antidipsogenic effect of enkephalins is reduced but not abolished by naloxone suggests that it is only in part, if at all, due to activation of opiate receptors.

These are entirely speculative hypotheses. Experiments are being carried out in our laboratory to check their validity.

Hyperpolarisation and depression of slow synaptic inhibition by enkephalin in frog sympathetic ganglion

EVIDENCE is accumulating to support the concept that the pentapeptides Met-enkephalin and Leu-enkephalin, the endogenous ligands for the opiate receptor, function as neuromodulators or neurotransmitters[1,2]. In the central nervous system the effects of enkephalins are complex and difficult to analyse, and their mode of action at the neuronal membrane level is still poorly understood. The most prominent action of enkephalins in the mammalian brain is depression of neuronal firing rate and it has been suggested that these peptides are inhibitory transmitters[1,2]. An increase in firing rate by enkephalins has, however, also been reported[3]. The response of central neurones to several putative transmitter substances is depressed or enhanced by enkephalins, suggesting a postsynaptic action[4,5]. It has also been shown that enkephalins suppress the K^+-induced release of noradrenaline[6], dopamine[7] and acetylcholine[7] from rat brain slices, indicating a presynaptic effect. The firing of myenteric neurones in the guinea-pig ileum is inhibited by enkephalins. This inhibition is probably due to a direct postsynaptic action of the enkephalins resulting in a hyperpolarisation of the neuronal membrane[8]. Most of the effects of enkephalins are antagonised by the specific opiate antagonist naloxone. Morphine produces effects very similar to those of enkephalins. Because of the possible role of enkephalins in inhibitory synaptic transmission, we studied the effects of Met-enkephalin on slow synaptic inhibition in frog sympathetic ganglion. We report here that Met-enkephalin causes a depression of the slow inhibitory postsynaptic potential (i.p.s.p.), probably mainly by a presynaptic action, and induces a hyperpolarisation of the ganglionic neurones. Both effects are antagonised by naloxone.

The experiments were carried out on the 9th or 10th paravertebral sympathetic ganglion of the frog (*Rana temporaria* and *R. esculenta*), using the sucrose gap technique[9]. Slow i.p.s.ps were elicited by repetitive stimulation of the ramus to the 8th ganglion. The simultaneously evoked fast excitatory postsynaptic potentials were selectively blocked by a low concentration of nicotine (30 μM) which was continuously present in the perfusion solution. Drugs were applied by switching from the original perfusion solution to one which differed only in its content of the drug to be studied. To detect changes in the ganglionic neurone resting membrane potential, which is reflected by the voltage across the sucrose gap, much care was taken to ensure a stable recording. In most experiments d.c. stability was better than $1\ \mathrm{mV\ h^{-1}}$.

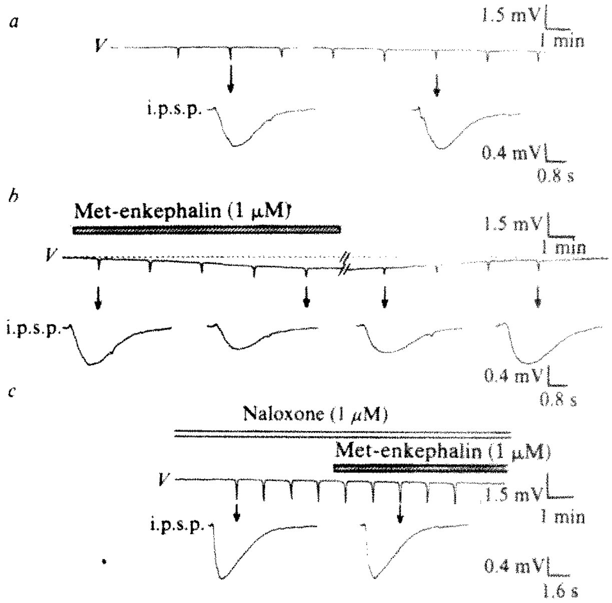

Fig. 1 Effects of Met-enkephalin on membrane potential and slow inhibitory postsynaptic potential (i.p.s.p.) in frog sympathetic ganglion. Experiments were carried out on the 9th or 10th paravertebral sympathetic ganglion using the sucrose gap technique[9]. The ganglion was continuously perfused with Ringer solution, with or without drug, containing in mM: NaCl 160; KCl 2.4; $CaCl_2$ 1.7 and HEPES 3.0; at *p*H 7.3 and temperature 21–23 °C. The postganglionic nerve trunk was perfused with isotonic KCl. Slow i.p.s.ps were elicited by repetitive stimulation of the ramus to the 8th ganglion through a suction electrode with a train of five pulses (0.1 ms; 10 Hz). Fast excitatory postsynaptic potentials were selectively blocked by the continuous presence of 30 μM nicotine in the perfusion solution. Upper trace in *a*, *b* and *c* represents continuous recording of voltage across sucrose gap (*V*) on the strip chart recorder. Downward deflections are slow i.p.s.ps. Lower traces, samples of enlarged slow i.p.s.ps recorded with a faster time base at different times as indicated by arrows. *a*, Control; *b*, hyperpolarisation and depression of slow i.p.s.p. by application of 1 μM Met-enkephalin as indicated by hatched bar. Dashed line in upper trace indicates baseline voltage. Both effects were reversed rapidly when the application of Met-enkephalin was stopped. *c*, Application of 1 μM naloxone (open bar) completely prevented the effects of subsequent application of 1 μM Met-enkephalin (hatched bar). Naloxone itself was without noticeable effect.

Application of 1 μM Met-enkephalin consistently caused a hyperpolarisation of the ganglionic neurones. In all experiments with Met-enkephalin a small drop in voltage across the sucrose gap (0.2–0.5 mV) was observed (Fig. 1*b*). Simultaneously with the hyperpolarisation, Met-enkephalin produced a marked depression of slow synaptic inhibition (Fig. 1*b*). In six experiments the amplitude of the slow i.p.s.p. was depressed by 39.3 ± 6.5% (mean ± s.d.). Duration and time course of the slow i.p.s.p. were not significantly affected by Met-enkephalin. Both the hyperpolarisation and the depression of the slow i.p.s.p. attained a constant level 5–10 min after the enkephalin had reached the ganglion, and were completely reversed on washing with enkephalin-free solution. Reapplication of Met-enkephalin produced the same effects.

D-Ala-Met-enkephalinamide at 1 μM caused similar effects (three experiments), but no attempt was made to compare the potencies of the two peptides. Morphine at 5 μM also caused a hyperpolarisation together with a depression of the slow i.p.s.p. (three separate experiments). Application of 1 μM naloxone fully reversed or prevented both the hyperpolarisation and the depression of the slow i.p.s.p. induced by Met-enkephalin (Fig.

0028-0836/79/0277—0053$01.00

1*c*). Naloxone itself had no noticeable effect. Thus, the enkephalin-induced effects can be considered to result from a specific interaction with opiate receptors. In myenteric neurones normorphine also causes a naloxone-reversible membrane hyperpolarisation which is accompanied by a fall in membrane resistance, as demonstrated by intracellular recording[10]. The hyperpolarisation of the sympathetic neurones reported here may be due to a similar mechanism.

There is evidence that the driving force for the slow i.p.s.p. is the difference between the membrane potential, V_m, and the K$^+$ equilibrium potential, E_K (ref. 11). Therefore, the depression of the slow i.p.s.p. by Met-enkephalin could be a consequence of the enkephalin-induced hyperpolarisation of the postsynaptic membrane. To test this possibility the relationship between slow i.p.s.p. amplitude and membrane potential was studied by varying the external K$^+$ concentration. The slow i.p.s.p. amplitude seemed to be linearly related to $V_m - E_K$ calculated with the aid of the Goldman equation, assuming standard values for the internal K$^+$ concentration (144 mM) and for the permeability ratio (P_{Na}/P_K, 0.04) (ref. 12). The estimated hyperpolarisation necessary to reduce the slow i.p.s.p. by 40% was much larger than the hyperpolarisation induced by Met-enkephalin, even if it is assumed that the enkephalin affects only C cells which generate the slow i.p.s.p. Thus, an additional effect seems to be involved.

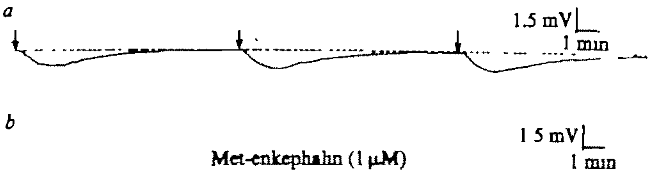

Fig. 2 Effects of Met-enkephalin on transient hyperpolarisations produced by single applications of dopamine (1 μl, 100 mM) just over the ganglion (arrows). *a*, Control; *b*, after application of 1 μM Met-enkephalin as indicated by hatched bar. Dashed line indicates baseline voltage across sucrose gap. Asterisk denotes beginning of hyperpolarisation induced by Met-enkephalin.

The slow i.p.s.p. in sympathetic ganglia is considered to be brought about by a catecholamine, probably dopamine, released from an interneurone which in turn is activated through a muscarinic cholinergic synapse[13]. To determine whether Met-enkephalin influenced the sensitivity of the ganglion to dopamine, small amounts of this substance were applied just over the ganglion with the aid of a motor-driven microinjection device. A single ejection of 1 μl of a 100 mM solution of dopamine produced a transient hyperpolarisation with a maximum amplitude of 0.5–3.0 mV in different experiments (Fig. 2*a*). Repeating the ejections at an interval of 10 min produced a constant response over a period of hours. Application of Met-enkephalin (1 μM) had only a slight effect on the dopamine response (Fig. 2*b*); in five experiments the amplitude was reduced by an average of 13.8 ± 6.1%. This reduction may be caused by the enkephalin-induced hyperpolarisation of the postsynaptic membrane as discussed above. These results suggest that the postsynaptic sensitivity of the ganglionic cells towards dopamine is hardly affected by Met-enkephalin.

The most likely explanation of the depression of the slow i.p.s.p. by Met-enkephalin reported here is an inhibition of transmitter release from presynaptic nerve terminals. Such a mechanism has been postulated to explain the inhibition of the K$^+$-induced release of various putative transmitter substances, including dopamine, from rat brain slices by enkephalin[6,7]; a presynaptic localisation of opiate receptors on dopaminergic nerve terminals has been demonstrated in rat striatum[14].

In conclusion, the present results show that Met-enkephalin exerts a dual effect in frog sympathetic ganglion; it induces a hyperpolarisation of the ganglionic neurones and in addition depresses slow synaptic inhibition. The hyperpolarisation probably involves a postsynaptic site of action, whereas the depression of slow synaptic inhibition may be presynaptic in origin, due to the inhibition of transmitter release from the nerve terminals.

mRNA species directing synthesis of milk proteins in normal and tumour tissue from human mammary gland

ONLY about one third of human metastatic breast carcinomas regress in response to hormone therapy[1,2], so there is a need to predict which tumours are of the hormone-dependent type. The usual method of prediction is based on the determination of hormone receptors in the tumour tissue[2–5]. However, only about one half of the tumours containing measurable oestrogen-receptor levels respond to hormone treatment[2] suggesting that receptors which bind the hormone *in vitro* may not always respond *in vivo*. An alternative approach has been to look for milk proteins within the tumour or serum, as lactation is a known hormone-dependent process. Although the rationale behind this approach has been substantiated in experimental systems[6,7] results with human mammary carcinomas are inconclusive[8–16], probably because of insufficient specificity[17] and sensitivity of the radioimmunological protein assay on which this method depends. In addition to technical problems the immunological approach has the drawback that it can only monitor the final product of hormone action, the mature protein, and not the initial RNA transcript(s). A better approach would seem to be an assay designed to detect differences in transcriptional rather than translational activity. As a preliminary step towards this objective, we describe here the isolation of poly(A)-containing RNA from a normal lactating human mammary gland, and demonstrate the presence of mRNA species which direct the synthesis in cell-free protein-synthesising systems of human casein and α-lactalbumin. Moreover, using the same techniques we have identified the presence of mRNA directing the synthesis of α-lactalbumin in poly(A)-containing RNA isolated from two out of five mammary tumours examined.

The tissue we describe as 'normal' was obtained from a nursing mother 15 days postpartum and consisted of a large (2 g) retention cyst, histologically virtually normal, which showed

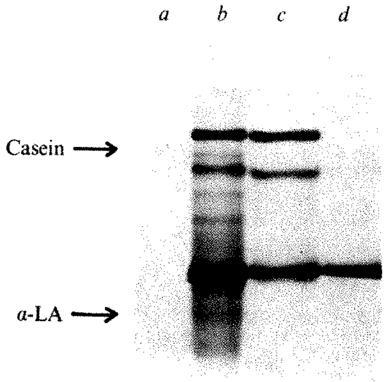

Fig. 1 Identification of casein and α-lactalbumin (α-LA) mRNAs in poly(A)-containing RNA isolated from lactating human mammary gland. A 2-g sample of frozen human lactating mammary gland (−70 °C) was pulverised with a hammer, then ground to a coarse powder in a mortar and pestle with periodic addition of liquid nitrogen. The powdered tissue was then rapidly transferred to a Teflon-in-glass Potter–Elvehjem homogeniser (0.4 mm clearance) containing 20 ml of 2% (w/v) SDS, 0.5 mg ml^{-1} proteinase K (Boehringer), 1 mM EDTA, 20 mM Tris-HCl, *p*H 7.6 and homogenised briefly at room temperature. It was then incubated at 45 °C for 1 h. After adding NaCl to 0.1 M, the lysate was extracted once with an equal volume of phenol–chloroform (1 : 1) saturated with 0.1 M NaCl, 1 mM EDTA, 20 mM Tris-HCl, *p*H 7.6. After separating the phases by centrifugation (3,000*g*, 10 min, 15 °C) nucleic acids were precipitated from the aqueous phase with 2.5 volumes of absolute ethanol at −20 °C for 1 h. The precipitate was collected by centrifugation (12,000*g*, 10 min, 0 °C) and redissolved in 11 ml of 1 mM EDTA, 20 mM Tris-HCl, *p*H 7.6. Solid caesium chloride (4.4 g) was added (0.4 g ml^{-1}) and the solution was distributed between two 12-ml capacity Beckman Ti50 centrifuge tubes, each containing a 3-ml cushion of 5.7 M caesium chloride in buffer. After overlaying with paraffin oil the tubes were centrifuged at 40,000 r.p.m. for 18 h at 20 °C in a Beckman Ti50 rotor. The supernatant was removed, the bottoms of the tubes sliced off, and the RNA pellets redissolved in buffer. After ethanol precipitation, the total RNA was subjected to two cycles of affinity chromatography on oligo(dT)-cellulose[18] to obtain the poly(A)-containing fraction. mRNA activity was determined in a wheatgerm cell-free protein-synthesising system[18], in the presence of ^{35}S-methionine. The products were electrophoresed on Maizel polyacrylamide gels[31] containing SDS[32], and visualised by fluorography[33]. Antisera to human α-lactalbumin and the major casein isolated from milk[9,20,34] were raised in rabbits[18]. Immunoprecipitates were prepared and processed as described previously[18]. *a*, Wheatgerm products synthesised in the absence of added RNA. *b*, Proteins synthesised on the addition of poly(A)-containing RNA from lactating human mammary gland. *c*, Proteins specifically precipitated by combined antisera to human α-lactalbumin and the major casein isolated from milk. *d*, Proteins specifically precipitated by anti-α-lactalbumin antiserum alone. Arrows indicate the positions of authentic mature milk proteins isolated from milk.

lactating breast tissue with areas of severe inflammation and abscess formation, but no evidence of malignancy. This and other tumour tissue samples were deep-frozen in liquid nitrogen within minutes of excision, and then stored at −70 °C before processing as described in the legend to Fig. 1.

The addition of the total cellular poly(A)-containing RNA isolated from normal human lactating mammary gland tissue to the wheatgerm cell-free protein-synthesising system resulted in a fourfold stimulation in the incorporation of ^{35}S-methionine into protein, when compared with that of the endogenous level in the absence of added RNA. Visualisation of the synthesised products by fluorography after separation by SDS-gel electrophoresis revealed the presence of three prominent bands of estimated molecular weights 26,500, 23,000 and 16,500 (Fig. 1). However, none of these products co-electrophoresed with the authentic human milk proteins (casein 25,000; α-lactalbumin 14,500), a situation we have previously reported with respect to the mRNA-directed synthesis of guinea pig milk proteins in the wheatgerm cell-free protein-synthesising system[18]. Further product analysis, using a mixture of antibodies raised against highly purified preparations of the major human casein component, and of human α-lactalbumin, resulted in the preferential precipitation of all three bands, whereas treatment with antisera raised against α-lactalbumin alone resulted in the precipitation of the lowest molecular weight component only (Fig. 1).

These results are consistent with the synthesis in the wheatgerm cell-free protein-synthesising system (or the reticulocyte lysate system—L. H. and R. C., unpublished observations) of a precursor form of α-lactalbumin (pre-α-lactalbumin). The situation concerning the remaining two higher molecular weight protein products is less clear. Human milk contains two caseins, the major component a well characterised protein (molecular weight 25,000), and a minor component, the κ-casein. We have purified and raised antisera against the former, although it is known that this cross-reacts immunologically with the κ-casein component[19]. Thus it seems reasonable to conclude that both bands represent human caseins, and that the higher molecular weight predominant protein probably represents a precursor to the major human casein, whilst the minor lower molecular weight protein probably represents the equivalent precursor to the κ-casein. However, as it is known that the major human casein is also highly phosphorylated[20], one cannot exclude the possibility that the anomalous mobility of the human caseins might be due to the absence of this post-translational event in the wheatgerm cell-free system. The relevance of pre-proteins and the absence of post-translation modification events in the wheatgerm cell-free system, concern the intracellular mechanisms involved in the synthesis of secretory proteins. These have been discussed in detail elsewhere with regards to guinea pig milk protein synthesis[18,21] and will not be discussed further in the context of this paper, except to note that in common with the guinea pig[18], rat[22], ovine and bovine milk proteins[23,24], the primary human milk protein translational products are probably synthesised as pre-proteins.

Processing of human mammary tumour tissue in an identical manner produced considerably lower yields of total RNA per g of starting material (15 A_{258} units per g) than the normal lactating tissue (75 A_{258} per g), although in all tissue samples processed in this manner the poly(A)-containing RNA recovered consistently represented about 1% of the total RNA population. Addition of the tumour-derived poly(A)-containing RNA to the wheatgerm cell-free system resulted in a slight stimulation in protein synthesising activity in two out of five tumours examined (all from postmenopausal patients). Analysis of the *in vitro* synthesised ^{35}S-methionine-labelled protein

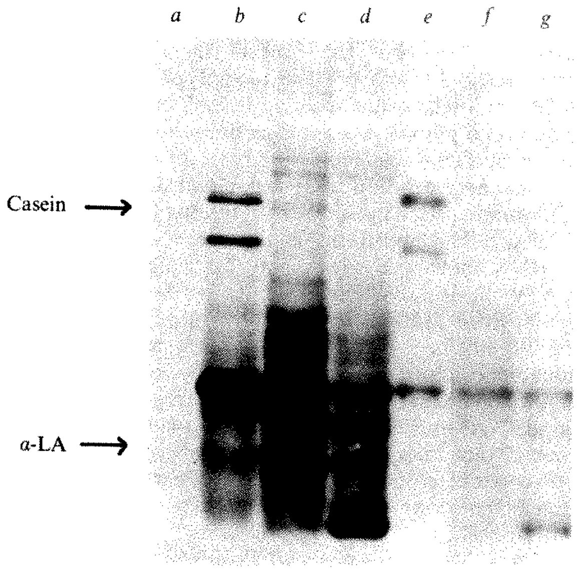

Fig. 2 Identification of α-lactalbumin mRNA in poly(A)-containing RNA isolated from human breast tumours. Experimental details as for Fig. 1, poly(A)-containing RNA being isolated from frozen breast tumours in the way described for lactating tissue. *a*, Wheatgerm products, synthesised in the absence of added RNA. *b–d*, Proteins synthesised on the addition of poly(A)-containing RNA from lactating human mammary gland (*b*), breast tumour 1 (*c*) and breast tumour 2 (*d*). *e–g*, Proteins specifically precipitated by combined antisera to human α-lactalbumin and the major casein isolated from milk; lactating human mammary gland (*e*), breast tumour 1 (*f*) and breast tumour 2 (*g*). Arrows indicate the positions of authentic mature milk proteins isolated from milk.

products (Fig. 2) showed in each case a prominent protein band which co-electrophoresed with human pre-α-lactalbumin, but no comparable bands which co-electrophoresed with the equivalent putative human pre-caseins. Antibody precipitation of the products with a mixture of antisera against both human α-lactalbumin and the major casein component confirmed that neither tumour contained significant levels of active mRNA which directed the synthesis of human caseins, though both contained mRNA which directed the *in vitro* synthesis of pre-α-lactalbumin. In addition to pre-α-lactalbumin, poly(A)-containing RNA from tumour 2 also directed the synthesis of a prominent lower molecular weight protein product (11,500), also precipitable by milk-protein antibodies. Subsequent work has shown that this is precipitated by antisera raised against α-lactalbumin, and not by antisera raised against human casein preparations.

Of the remaining three mammary tumours processed, although poly(A)-containing RNA was recovered in the expected yield, all showed inhibitory activity in a variety of cell-free protein-synthesising systems, possibly a function of low molecular weight nuclear RNA species known to inhibit cell-free protein-synthesising systems[25–28].

As well as demonstrating mRNA-directed synthesis *in vitro* of human milk proteins, our results provide firm evidence for the presence, in significant levels, of mRNA directing the synthesis of α-lactalbumin but not casein, in two out of five mammary tumours examined. Both were from postmenopausal patients, one of which (T1—an adenocarcinoma) had had no children, whilst the other (T2—an invasive duct carcinoma) had had one breast-fed child. Neither had undergone either hormone therapy or chemotherapy before surgery.

α-Lactalbumin has previously been identified in the cytosol fraction of mammary tumours, using radioimmunoassay. One study in particular[16] provided good evidence for the presence of α-lactalbumin in 38% of all mammary carcinomas examined. Of these, 53% of the ER-positive carcinomas contained α-lactalbumin, but only 5% of the ER-negative carcinomas, results which strongly suggest that the presence of α-lactalbumin may indicate an intact oestrogen-receptor mechanism, and may therefore provide a useful marker for identifying tumours responsive to hormone therapy. Our preliminary results support such a concept. Our approach is at present time-consuming and therefore not suitable for routine diagnostic application. However, it should prove possible to apply modern recombinant genetic techniques to this system, as has been done with both adult and fetal globin genes[29], thus providing in the form of a recombinant DNA molecule the basis of a highly sensitive nucleic acid hybridisation assay capable of detecting low levels of milk protein mRNA sequences in relatively small samples of breast tissue. This approach has the additional advantage that other RNA molecules which may be inhibitory in cell-free protein synthesising systems will have no deleterious effect on molecular hybridisation. The potential of molecular hybridisation has already been demonstrated by Rosen and Socher[30] who examined the effect of hormones on the levels of rat casein mRNA by hybridisation to a complementary DNA copy of the casein mRNA, thus by-passing any inconsistencies in radioimmunoassay technology, and the dependence of such assays on the presence of the final translational product, and not the initial product of hormone-dependent gene expression, the primary RNA transcript.

We thank Mr D. Ralphs and Professor N. Woolf of The Middlesex Hospital Medical School for providing normal and tumour tissues, histological reports, and for helpful discussions. This work was supported by the Cancer Research Campaign.

Translocation 8;14 in an ataxia telangiectasia-derived cell line

THE incidence of lymphomas is 10,000 times greater than normal in patients with immunodeficiency syndromes[1] and also in ataxia telangiectasia (AT), which very often involves IgA deficiency[2]. In addition to its other characteristic features, AT is usually associated with a defect in DNA repair[3] and a translocation involving chromosome 14 in the peripheral leukocytes[4]. Another feature is a high prevalence of Epstein–Barr virus early antigen (EBV-EA) antibodies[5] in the sera of AT patients. This is significantly higher than in normal human sera (<10%) and resembles that found in cases of Burkitt's lymphoma (BL). It is thus interesting that translocations involving chromosome 14 have been described in BL cells as well as in other lymphomatous cells[6–8]. This chromosome marker is also found in BL cell lines containing EBV[9]. It is not induced by EBV alone, however, because it is not found in EBV-positive, but non-lymphomatous cell lines, established spontaneously or by transformation of normal peripheral blood leukocytes[10]. We have therefore investigated whether in BL and AT some target cells of EBV infection might be genetically 'defective' lymphoid cells that could more easily be transformed into malignant cells (with characteristic chromosome markers) when exposed to EBV or other carcinogens. To do this we infected lymphoid cells from AT patients *in vitro* with EBV, and we report here a translocation $t(8q^-; 14q^+)$ established in one of the resulting cell lines.

The translocation seems to be identical to that found in BL[6,7]. This suggests that *in vitro* transformation of peripheral lymphocytes from a patient with a genetic predisposition to

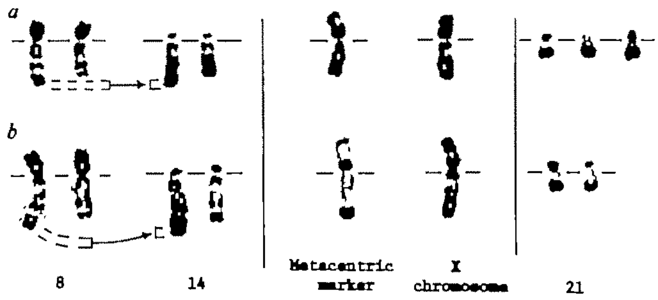

Fig. 1 R-banded chromosome rearrangements in *a*, ataxia telangiectasia- *b*, Burkitt lymphoma-derived cell lines

chromosome damage favours the development of a chromosome rearrangement already described in lymphoid malignancies[8,10].

Phytohaemagglutinin-stimulated peripheral blood lymphocytes from a 17-yr-old male patient with AT were analysed by R-banding. In addition, a cell line (CB-1) was established from his blood lymphocytes by transformation *in vitro* with EBV obtained from the saliva of a patient with infectious mononucleosis according to a method previously described[11]. Karyotypes were prepared from this cell line 6, 8 and 12 months after it had been established. Structural rearrangements were compared with those seen in a BL-derived cell line (HR1K-m) which was examined on two separate occasions, 1 month apart, and with those of a control lymphoblastoid cell line established from normal cord blood lymphocytes transformed by EBV (Cb 8-11). Chromosomes of the three cell lines were analysed using a modification of the original technique of Dutrillaux and Lejeune[12]. R-bands obtained with this technique reveal abnormalities involving relatively small portions of chromosomes.

No significant chromosomal abnormalities were observed in 108 metaphases from the peripheral blood leukocytes of the patient. However, translocations involving 14q have been described in the blood of some other AT patients[4]. The major part of 14q (break point in band 14q12) is translocated to the end of the homologue 14 or chromosomes 6, 7 or X (ref. 4). As Fig. 1 shows, an AT-derived cell line shows three different chromosomal abnormalities: a translocation $t(8q^-;\ 14q^+)$, a metacentric marker of the size of an X chromosome with a large dark band just above the centromere, and a trisomy 21. The first two abnormalities closely resemble those seen in the BL-derived cell lines, Burkitt tumour cells and other lymphomatous cells. In the control cell line (Cb 8-11) derived from normal cord blood lymphocytes transformed by EBV, chromosomes 8, 14 and 21 were normal and no metacentric marker was seen. All 35 metaphases from the AT-derived cell line contain the translocation t8;14 and the metacentric marker (Table 1). Trisomy 21 is absent only from three metaphases with 47 chromosomes. This could be interpreted as either the presence of a second clone or the loss of a G chromosome. It is interesting that although the patient had no features of the trisomy 21 syndrome, two first-degree cousins of his father had given birth to children with Down's syndrome.

Table 1 Chromosome markers in ataxia telangiectasia- and Burkitt lymphoma-derived cell lines

Cell line origin	Photographed metaphases Total no.	No containing a t(8,14)	 Metacentric marker	 Trisomy 21
AT+EBV	35	35	35	32
BL	36	36	36	0

AT, Ataxia-telangiectasia; BL, Burkitt lymphoma (cell line HRI-Km); EBV, Epstein–Barr virus.

EBV can transform peripheral blood lymphocytes from normal donors into permanent cell lines which remain diploid for a long time after establishment. Non-random chromosome abnormalities are acquired on prolonged culture. After more than a year, gains particularly involving five autosomes (numbers 3, 7, 8, 9 and 12) and sex chromosomes have been reported in these lymphoblastoid cell lines[13]. In our investigation, chromosome rearrangements similar to those seen in BL-derived cell lines were already present at the time of the first cytogenetic analysis, 6 months after EBV transformation.

Because both cell lines come from male donors, the possibility of contamination of one cell line by another cannot be excluded by using the Y chromosome as a distinctive marker. However, they have different histocompatibility antigens (CB-1: A3AW32, B5BW35, CW2; HR1K-m: A28AW34, B15BW49, CW2). Although an unusually high incidence of chromosomal damage[14] and defective DNA repair[3] has been reported in AT skin fibroblasts, rates of SV40 transformation of these cells are no higher than those for normal cells[15]. Furthermore, marker chromosomes similar to that described here have not been identified in these fibroblasts. In our experiment, AT lymphocytes were found, after transformation *in vitro*, to have a 14q translocation which seems to be a marker of lymphoid malignancy[4,7,8,16].

It seems that the addition of EBV to apparently normal lymphocytes of an AT patient has revealed either a quiescent clone or an increased chromosome fragility. This is interesting because EBV transformation of lymphoid cells from normal individuals has not so far induced the characteristic chromosome 14 marker seen in lymphomatous cells[10]. Further studies will be necessary to characterise CB-1 as a 'lymphomatous cell line' or as a 'lymphoblastoid cell line' as proposed by Nilsson[17]. The role of genetic factors such as defective DNA repair, and of susceptibility to oncogenic agents in cell transformation and malignancy may thus be clarified. Cell lines derived from lymphocytes of AT patients and others with increased susceptibility to lymphoid malignancy, might become useful tools for the study of malignant transformation. Lymphocytes from other AT patients are now being transformed by EBV, and cytogenetic studies will be made to discover if a correlation exists between early chromosome rearrangements and future clinical course, with special attention to the development of lymphomas.

Re-evaluation of the number of specific β-adrenergic receptors on muscle cells

IT has been reported by Atlas, Hanski and Levitzki that muscle cells have an unusually high number of β adrenoreceptors, 80,000 per cell[1]. However, we consider the pharmacological characterisation of these receptors as specific β adrenoreceptors unsatisfactory. We report here that the number of specific β adrenoreceptors in a similar but not identical muscle cell line of the same origin is 8,000 rather than their stated figure of 80,000, and is therefore comparable to that found on C6 glioma cells.

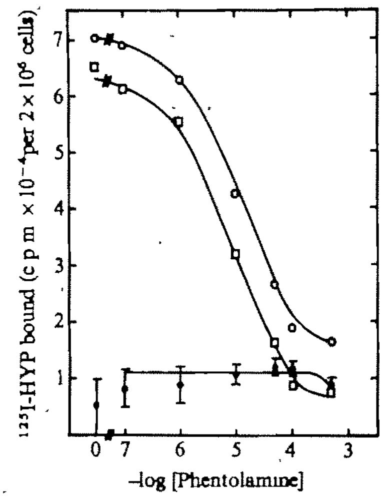

Fig. 1 The effects of phentolamine on ^{125}I-HYP binding to intact L8 muscle cells. An L8 cell line was established by serial passage of rat myoblasts[6]; it has properties similar to those of the L6P cell line. The cells were grown on Falcon or Nunc tissue cultures plates in Dulbecco's minimal essential medium (Gibco) supplemented with 10% fetal calf serum (Gibco), under an atmosphere of 95% air, 5% CO_2. Trypsinised, exponentially growing cells were distributed on to 6-cm plastic plates. They were then allowed to grow and recover for 48 h in fresh medium before the binding assay. In this condition the cells multiplied about ninefold. This means that if trypsin has any effect on the β-receptor density, it would affect only 10% of the cells. HYP was iodinated by the method of Maguire *et al.*[4]. 2×10^6 cells per 6-cm plate were incubated with ^{125}I-HYP (125,000 c.p.m. or 25 pM) in 2 ml of phosphate-buffered saline (PBS) and various concentrations of phentolamine in the absence (○) or presence (□) of 10^{-7} M (–)propranolol Prewashing of the plates, their incubation with the radioactive ligand and further washing were carried out as previously described[2]. The washing covers a total period of 60 min at 37 °C. Such a prolonged washing has negligible influence on the dissociation of ^{125}I-HYP specifically bound but markedly decreases the nonspecific binding (not shown). This observation is compatible with what is found in the literature concerning ^{125}I-HYP binding. The dissociation of ^{125}I-HYP specifically bound is observed only when an excess of cold antagonist is added during the washing[4,7]. In the absence of excess cold antagonist, binding seems to be virtually irreversible. The amount of specifically bound (●) ^{125}I-HYP is the calculated difference between total (○) and nonspecific binding (□).

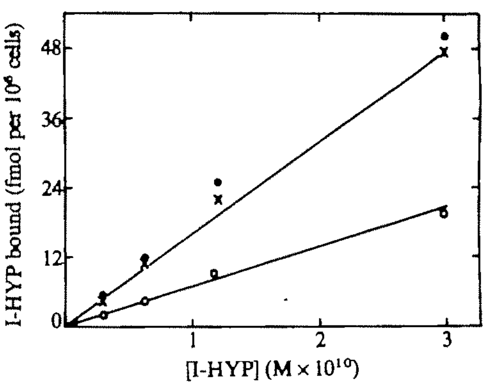

Fig. 2 ^{125}I-HYP binding to L8 muscle cells in the absence of phentolamine. About 2×10^6 cells per 6-cm plate were incubated with 2 ml of PBS containing various concentrations of ^{125}I-HYP, in the absence of phentolamine, without propranolol (●) and in the presence of 2.5×10^{-5} M (○) or 10^{-7} M(×) (–)propranolol and assayed for binding as described in Fig. 1.

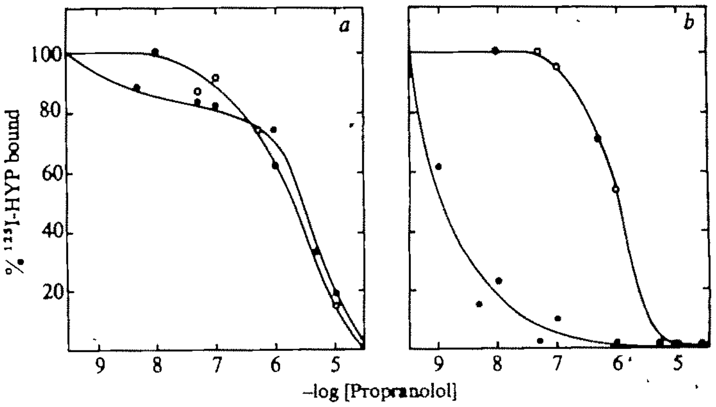
We have recently devised a method to measure the number of β adrenoreceptors on intact C6 glioma cells[2]. That study demonstrated that tissue culture cells bind large amounts of ^{125}I-hydroxybenzylpindolol (^{125}I-HYP) in a nonspecific manner. This nonspecific binding can be largely eliminated by carrying out the binding assays in the presence of high concentrations of phentolamine as originally observed by Sporn and Molinoff[3] in membranes from rat brain. Figure 1 shows that 5×10^{-5} M phentolamine displaces 75% of the nonspecifically bound ^{125}I-HYP but does not modify the specifically bound ligand.

In addition, the concentration of cold competing antagonist or agonist used to measure the nonspecific binding must be chosen according to its dissociation constant and in relation to the concentration of radioactive ligand. In our study, 10^{-7} M (–)propranolol was a satisfactory concentration ($100\times K_D$). Higher concentrations are not necessary to displace ^{125}I-HYP bound to β receptors and such high concentrations can displace ^{125}I-HYP bound nonspecifically.

Figure 2 shows the difference in two nonspecific binding curves obtained on L8 muscle cells in the presence of two different concentrations of (–)propranolol, 2.5×10^{-5} M and 10^{-7} M in the absence of phentolamine. The difference between these two curves represents displacement of nonspecifically bound radioactive ligand.

This conclusion is supported by the results shown in Fig. 3. 10^{-7} M (–)propranolol, the pharmacologically active optical

Fig. 3 Inhibition of ^{125}I-HYP binding to L8 muscle cells by propranolol. Binding was carried out as described in Fig. 1, in the absence (*a*) or presence (*b*) of 5×10^{-5} M phentolamine, with (+)propranolol (○) or (–)propranolol (●). 100% and 0% binding refer, respectively, in *a* to 100,000 and 30,000 c.p m. and in *b* to 40,000 and 22,000 c p m. These experiments were done in parallel on the same number of cells and the results can thus be compared quantitatively as well as qualitatively.



0028-0836/79/0277–0058$01.00

isomer, provokes nearly maximal displacement from stereospecific sites. The reduction in binding observed in the absence of phentolamine with concentrations of propranolol higher than 10^{-7} M is clearly non-stereospecific and thus represents displacement from nonspecific sites. Figure 3*b*, in which most of the nonspecific ^{125}I-HYP bound has been removed in the presence of phentolamine, strikingly illustrates the stereospecific displacement from β receptors. Atlas *et al.* carried out their assays with similar concentrations of radioactive ligand but in the absence of phentolamine. In these conditions, their concentration of ($\pm$)propranolol, 5×10^{-5} M, was two orders of magnitude too high and displaced ^{125}I-HYP bound to sites unrelated to β-adrenergic receptors. It should be noted that the relative amount of nonspecifically bound ^{125}I-HYP is highly variable among different cell lines. In turkey erythrocytes, nonspecific binding is much lower and thus the use of 10^{-7} M or 5×10^{-5} M ($\pm$)propranolol would not change the amount of displaced ^{125}I-HYP in such a dramatic fashion. In Fig. 4, the specific binding of ^{125}I-HYP to β adrenoreceptors has been measured in the presence of phentolamine using 10^{-7} M ($-$)propranolol as the competing ligand. Scatchard analysis of these data shows that L8 muscle cells have 7,900 ± 1,600 specific β adrenoreceptors per cell. This number is not significantly different from that obtained in C6 glioma cells[2,4,5]. The use of 2.5×10^{-5} M ($-$)propranolol (Fig. 2) without phentolamine gives an erroneously high number of receptors per cell, thus explaining the figure given by Atlas *et al.*

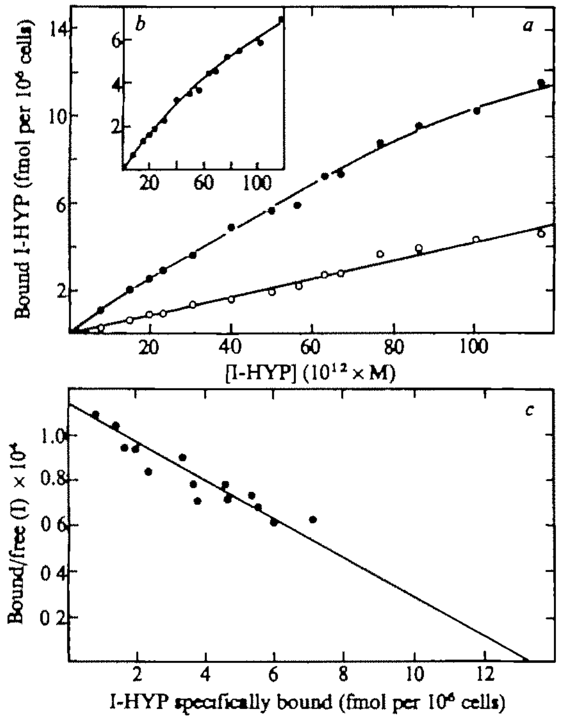


Fig. 4 Binding of ^{125}I-HYP to intact L8 muscle cells in the presence of phentolamine. Assays were carried out in standard conditions. 3×10^{6} cells per plate were incubated with 5×10^{-5} M phentolamine and various concentrations of ^{125}I-HYP. In *a*, the total amount of ^{125}I-HYP bound (●) and the nonspecifically bound ligand remaining in the presence of 10^{-7} M ($-$)propranolol (○) are plotted as a function of the ^{125}I-HYP. Specific binding, defined as the difference between the total and the nonspecific binding, is plotted in *b*. The saturation value (13.2 fmol per 10^{6} cells or 7,950 receptors per cell) and the K_D (1.2×10^{-10} M) has been calculated using a linear regression curve (coefficient of correlation = 0.92) obtained with the Scatchard plot represented in *c*.

Our results demonstrate the importance of the choice of experimental conditions in the determination of the true number of stereospecific β receptors. Although the number of β adrenoreceptors on rat muscle cells of the L8 or L6 line does not single them out for receptor purification, it is, however, sufficient to analyse β-adrenoreceptor distribution during muscle cell fusion.

We thank Dr E. Schell-Frederick for revising our manuscript and Mrs D. Leemans fo secretarial assistance. This work was supported by grants from the Caisse Générale d'Epargne et de Retraite (Fonds Cancérologique) to Drs J. E. Dumont and R. Kram. L8 cells were obtained from D. Yaffe.

ATLAS, HANSKI AND LEVITZKI REPLY—Our reply will be divided into two parts: first, the validation of our results[1], and second, the demonstration that the methodology used by Pochet and Schmitt is inadequate.

To consider our first point. The difference between the binding curve of ^{125}I-($\pm$)hydroxybenzylpindolol (HYP) in the absence and in the presence of 5.0×10^{-5} M ($\pm$)propranolol monitors the reliable number of β adrenoreceptors in intact cells as well as in membrane fragments prepared from these cells. Figure 1 shows Scratchard plots of the binding of ^{125}I-($\pm$)-HYP to L6P cells removed from the growth plate by EDTA as compared with L6P cells removed by using trypsin. It can be seen that trypsin causes a five- to sixfold decrease in the number of β adrenoreceptors. The destruction of receptors by trypsin is well documented for several hormone receptors including β adrenoreceptors. In contrast to the effect of trypsin on the number of β adrenoreceptors detected, no change was observed in the number of ^{125}I($\pm$)HYP binding sites by changing the fluidity of the cell membrane. A large change in the fluidity of the turkey erythrocyte membrane has no effect on the extent of the 'nonspecific' or specific ^{125}I-($\pm$)HYP binding. Table 1 summarises results demonstrating that the ratio between cholesterol and phospholipids has no influence on the binding of ^{125}I-($\pm$)HYP to intact turkey erythrocytes or to membrane fragments prepared from these cells. Further details on this particular point are given elsewhere[2]. The fluidisation of turkey erythrocyte membranes using free fatty acids also has no influence on the number of specific ^{125}I-($\pm$)HYP binding sites on the turkey erythrocyte or on the affinity of these receptors to the β blocker[11].

The number of β adrenoreceptors on a turkey erythrocyte, as measured by ^{125}I-($\pm$)HYP, is identical to the number found by the ^{3}H-($\pm$)propranolol technique introduced by us[3-5]. Furthermore, the measurement of the content of β-adrenergic receptors using ^{3}H-($\pm$)isoprenaline again gives similar results[3]. It is worth noting that the difference between ^{125}I-($\pm$)HYP binding in the absence and in the presence of ($\pm$)propranolol gives linear Scatchard plots, thus indicating that a single class of ^{125}I-($\pm$)HYP binding sites is being monitored. If Pochet and Schmitt were correct in their assertion that ($\pm$)propranolol displaced both specific and nonspecific ^{125}I-($\pm$)HYP, one would

Table 1 Effect of cholesterol enrichment and of cholesterol depletion on the β-adrenergic system

Treatment	Cholesterol to phospholipid ratio	^{125}I-HYP binding (pmol per mg)	^{125}I-HYP receptor dissociation constant
No treatment (control)	1.0–1.2	0.55 ± 0.05	$(6.8\pm0.5)\times10^{-11}$
Cholesterol depleted	0.5–0.6	0.53 ± 0.05	$(7.5\pm0.05)\times10^{-11}$
Cholesterol enriched	1.45–1.55	0.54 ± 0.05	$(6.9\pm0.5)\times10^{-11}$

observe at least two classes of ^{125}I-(±)HYP binding sites which should have given curvilinear Scatchard plots. In our binding studies on intact cells of different types, L6P cells, HeLa cells, turkey erythrocytes and turkey reticulocytes, we have consistently found a single class of ^{125}I-(±)HYP binding sites[2,6]. It should be noted that the successful use of ^{125}I-(±)HYP in the determination of the number of β adrenoreceptors on intact cells was first introduced by Aurbach *et al.*[7] and has since been adopted by several laboratories, including our own. Furthermore, the methodology used by us was originally introduced by Aurbach *et al.*[8] and was demonstrated to be an equilibrium technique[8,9]. Maguire *et al.*[9] have also used propranolol (1.0×10^{-5} M (−)propranolol) for the displacement of the nonspecific ^{125}I-(±)HYP bound, obtaining reliable and consistent binding data.

Schmitt and Pochet are correct in asserting that concentrations lower than 5.0×10^{-5} M (±)propranolol should be sufficient to displace the specific ^{125}I-(±)HYP bound. Indeed, 2.0×10^{-7} M, 2.0×10^{-6} M and 2.0×10^{-5} M (±)propranolol displace bound ^{125}I-(±)HYP to a similar extent. Interestingly, using the usual methodology as described [1,2,6-10], we found that inclusion of 2.5×10^{-5} M phentolamine in the binding mixture reduces the nonspecific binding of ^{125}I-(±)HYP by 10–15% but does not modify the pattern of ^{125}I-(±)HYP to the specific sites. As the effect of phentolamine is marginal (see also below), we find no need to use it. These results are similar to those reported by Brown *et al.* for turkey erythrocytes[10].

On our second point, the methodology used by Pochet and Schmitt suffers from several flaws which cast serious doubts on the validity of their experimental approach. (1) What the authors call 'nonspecific' ^{125}I-(±)HYP binding is removed by six washings, 10 min each, at 37 °C. The methodology used by the authors is cited in their manuscript (their ref. 2). As the half life of ^{125}I-(±)HYP on the β adrenoreceptors is $t_{\frac{1}{2}} = 7.2$ min at 30 °C (ref. 7) and $t_{\frac{1}{2}} = 2.57$ min at 35 °C (ref. 8), it is clear that most of the specific ^{125}I-(±)HYP bound to the β adrenoreceptors is washed out. Therefore, the methodology used is not an equilibrium technique and cannot give reliable data. (2) The cells are removed by trypsin. As we have shown (Fig. 1 and ref. 6), the β adrenoreceptors on L6P cells are destroyed in these conditions. This was the reason EDTA[1,6] was used instead. No evidence is provided by the authors that the 'recovery' period results in the resynthesis of the β adrenoreceptors. (3) The authors use phentolamine to displace nonspecific ^{125}I-(±)HYP binding. At least in one case (rat hypothalamus membranes) phentolamine was found to displace ^{125}I-(±)HYP from β adrenoreceptors[12]. It should be noted that phentolamine, at the concentration range of 1.0×10^{-5} to 1.0×10^{-4} M, can block the isoprenaline-dependent adenylate cyclase activation in neuroblastoma–glyoma hybrids (unpublished data). In our experiments, phentolamine had an insignificant effect. This large variability in phentolamine action on different cells convinces us that its use in binding studies is dispensable. (4) As to the quality of the binding curves presented by Pochet and Schmitt, their Fig. 2 does not show any of the curvature which should be observed if the binding of ^{125}I-(±)HYP has a saturable component. The data presented in their Fig. 4 do not demonstrate that saturation has been achieved. The data can be easily fitted by a straight line. A replot of the raw data in their Fig. 4*a*, according to Scatchard, shows that only 43% saturation has been achieved. If one believes that the remaining 57% behave in a similar fashion, the maximal number of receptors should be 9,650 receptors ($K_D = 1.6\times10^{-10}$ M) per cell. In view of the methodology used by the authors, we believe that this number underestimates the true number of β receptors by about 80–90%. (5) The authors used L8 cells, whereas we used L6P cells.

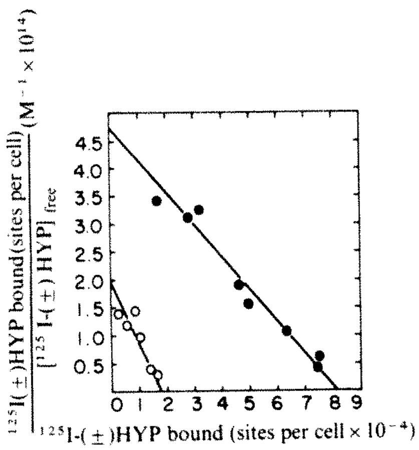

Fig. 1 ●, L6P cells removed by EDTA treatment. Experimental details are given elsewhere[1,6]. ○, L6P cells were removed by treatment with trypsin. The growth medium was removed from the tissue culture bottle and the cells were incubated with 50 ml 130 mM saline, containing 20 mM Tris-HCl buffer, *p*H 7.4, and 500 μg ml^{-1} trypsin, for 30 min at 37 °C. The cells were detached from the bottle, centrifuged at 500 *g*, and washed twice with trypsin-free saline containing buffer. The binding procedure was the same as described elsewhere[1,2,6].

Note added in proof: Recently the density of β-receptors was measured on L84 rat skeletal myogenic muscle cells, using an ultrastructural probe for the receptor. Using this technique receptor density was found[13] to be 71 ± 19 receptors per μm^2. That is, 50,000 to 80,000 receptors per cell—similar to the closely related L6 cells.

Minor differences between nucleotide sequences of mild and severe strains of potato spindle tuber viroid

VIROIDS are the smallest replicating pathogenic agents known[1]. Composed entirely of RNA, they have genome sizes in the range of 330–380 nucleotides[2], 10 times smaller than the smallest bacteriophage of *Escherichia coli*[3]. Although there is no evidence for the existence of a protective protein coat for viroids, they infect a wide variety of plants and in many produce

0028-0836/79/0277—0060$01.00

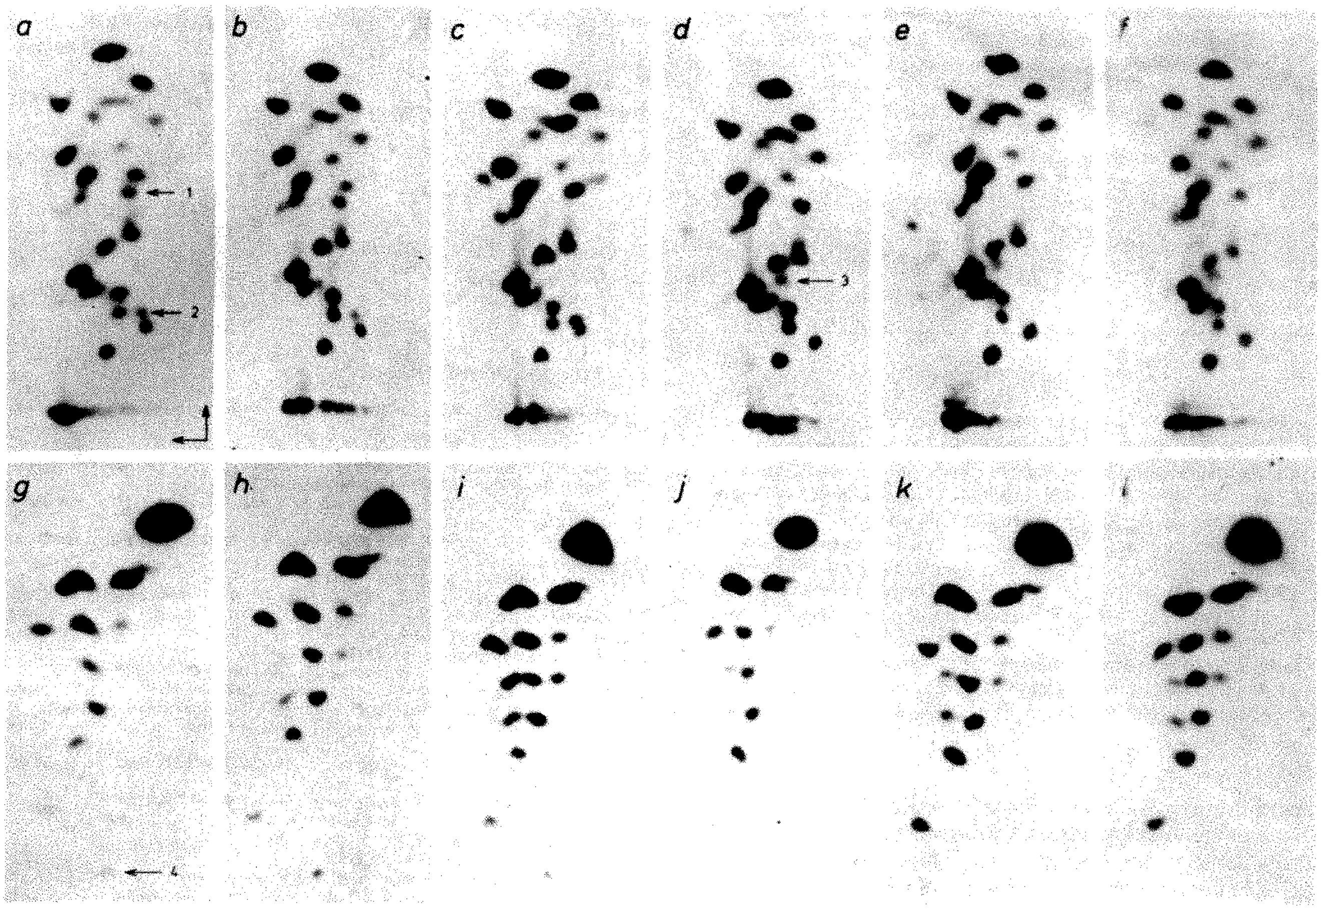

Fig. 1 Ribonuclease T1 and pancreatic ribonuclease fingerprints of two severe, one intermediate and three mild strains of PSTV. 1×10^6 c.p.m. aliquots of each ^{125}I-labelled viroid were dried down in silicone-treated test tubes and digested with 2 μl of either ribonuclease T1 (1 mg ml^{-1} for 40 min at 37 °C) or pancreatic ribonuclease (1 mg ml^{-1} for 30 min at 37 °C) in 0.01 M Tris–HCl, *p*H 7.6, 0.001 M EDTA in the presence of 10 μg of tRNA carrier as described previously[12,20]. The origin of each autoradiograph is at the lower right. The first dimension (right to left) consists of high-voltage electrophoresis on cellulose acetate at *p*H 3.5, while the second consists of ascending RNA homochromatography on thin layers of DEAE-cellulose[20]. Fingerprints were exposed to Dupont Cronex 2 X-ray film at −70 °C in 14in. × 17in. Halsey–Radelin cassettes in the presence of two Dupont Lightning-plus intensifying screens. Fingerprints of 6 of the 11 PSTV isolates studied are shown. In each case, the ribonuclease T1 fingerprint is placed vertically above the pancreatic ribonuclease fingerprint; *a* and *g*, severe isolate, PS; *b* and *h*, severe isolate, SE; *c* and *i*, intermediate isolate, PD; *d* and *j*, mild isolate, PM; *e* and *k*, mild isolate, 6; *f* and *l*, mild isolate, 12. For an account of the source of each of these isolates, see the footnotes to Table 1. The numbered arrows in panels *a*, *d* and *g* indicate spots which are diagnostic for one or another strain of PSTV as discussed in the text and summarised in Table 1.

severe disease symptoms[1,4]. The molecular mechanisms by which viroids replicate and interact with their hosts are not yet understood. In its most severe form, the disease[5,6] caused by potato spindle tuber viroid (PSTV) causes general stunting of potato plant growth, deformity of the upper foliage, and production of disfigured potatoes[5]. Mild strains of PSTV which produce barely detectable symptoms have also been isolated[7]. Furthermore, plants infected by mild strains are somehow protected from developing symptoms following subsequent inoculation with severe strains[8,9]. This biological protection phenomenon has been called cross-protection[7]. As the only known component of viroids is RNA, mild and severe strains must differ in nucleotide sequence. The study described here aimed to determine the extent of this difference.

Four independently maintained severe, one intermediate, and six mild isolates of PSTV were propagated in Rutgers tomato plants, extracted and purified as described elsewhere[10], labelled *in vitro* with ^{125}I (ref. 11), and subjected to two-dimensional RNA fingerprint analysis[11–13]. Because the fingerprints obtained showed evidence of variable quantities of host RNA contaminants (data not shown), the ^{125}I-labelled viroid preparations were repurified by electrophoresis in 5% polyacrylamide gels[11] and fingerprinted once again.

Ribonuclease T1 and pancreatic ribonuclease fingerprints of two severe, one intermediate, and three mild PSTV isolates are shown in Fig. 1. The other two severe and three mild isolates studied did not differ significantly from those illustrated. Visual inspection reveals that all six ribonuclease T1 fingerprints closely resemble each other, as do all six pancreatic ribonuclease fingerprints. However, a few differences are evident. The four spots found to be diagnostic for the various strains are indicated in Fig. 1 by numbered arrows. The four severe strains have spots 1, 2 and 4 but lack spot 3 (Fig. 1 *a*, *b*, *g*, *h*). The intermediate strain has spots 2 and 4 but lacks spots 1 and 3 (Fig. 1 *c*, *i*). The six mild strains have spot 3 but lack spots 1, 2 and 4 (Fig. 1 *d*, *e*, *f*, *j*, *k*, *l*).

Secondary enzymatic digestion of all oligonucleotides from the fingerprints shown in Fig. 1 *a*, *d*, *g*, *j* followed by identification of cleavage products (as described in refs 12, 13) revealed only two further differences between the mild and severe strains of PSTV. The pancreatic ribonuclease fingerprint of mild PSTV contained the hexamer AAGGAC and the tetramer GAGC, neither of which can be detected by visual examination as all strains of PSTV analysed have two other hexanucleotides, GAGAAC and GGAAAC which co-migrate with AAGGAC; and AGGC which co-migrates with GAGC. As the sequence of spot 4 is AAAAAAGGAC, there is the attractive possibility that the new hexanucleotide AAGGAC found in mild strains is the result of the replacement of the fourth A-residue of spot 4 by a pyrimidine. These sequences were determined as described previously[12,14–17]. The intermediate strain (Fig. 1 *i*) lacks AAGGAC and contains GAGC.

Table 1 Oligonucleotide differences observed among severe, intermediate and mild strains of PSTV

Oligonucleotide description*	PSTV strain† Severe	Intermediate	Mild
spot 1	+‡	−	−
spot 2	+	+	−
spot 4	+	+	−
spot 3	−	−	+
AAGGAC	−	−	+
GAGC	−	+	+

* Spots 1, 2, 3 and 4 are those indicated by numbered arrows in Fig. 1.

† Eleven isolates of PSTV were selected for these studies. One of the four severe isolates (A) was obtained from the Schultz Collection of Potato Pathogens at Beltsville, Maryland. The other three severe isolates (PS, D and SE) were obtained over the course of 30 yr from naturally infected potatoes in field plots of the Cornell University Potato Breeding Program by Dr Karl H. Fernow. This was also the source of five of the six mild isolates (PM, 6, 7, 10 and 11). The sixth mild isolate (12) was recovered in autumn 1977 from a naturally infected potato plant at Riverhead, New York by Dr Fernow. The intermediate isolate, PD, was the gift of Dr T. O. Diener and was the one we used in previous RNA fingerprinting studies[11,13,16].

‡ + indicates the presence of the specified oligonucleotide in fingerprints of the PSTV strain in question. − indicates the absence of the specified oligonucleotide from fingerprints of the PSTV strain.

Thus, as shown in Table 1, while severe and mild strains of PSTV are uniquely characterised by the presence and absence of particular spots in their fingerprints, the intermediate strain has no such singular features. Detailed study of all data derived from oligonucleotide secondary analysis also permits us to estimate that mild and severe strains differ in 2–10 of their nucleotide residues (E.D. and H.D.R., unpublished observations).

These results demonstrate that the marked contrast between severe and mild symptoms must be explained on the basis of relatively few specific nucleotide sequence differences. As noted above, one of the sequence differences seems to occur at the fourth residue of the decanucleotide AAAAAAGGAC (spot 4: see Fig. 1 and Table 1). This can be identified as position 120 within the sequence of an intermediate strain[10] of PSTV (refs 18, 19). Further sequence analysis will be required before the exact positions of the other oligonucleotides associated with the mild-severe difference can be assigned. Such studies should also allow us to determine whether the residues important for the pathogenic properties are clustered in a small region of the viroid genome or are widely separated.

Although mild and severe strains of PSTV have very similar nucleotide sequences, additional studies indicate that such extensive sequence homology is not a prerequisite for cross-protection. Although comparative RNA fingerprint analysis of PSTV, citrus exocortis viroid (CEV) and chrysanthemum stunt viroid (CSV) have demonstrated that the sequences of these three viroids differ extensively from each other[11,13,16], biological studies have recently shown[9] that mild strains of PSTV cross-protect, not only against severe strains of PSTV, but also against CEV and CSV.

If cross-protection and disease symptom formation are determined by common features within a portion of the viroid genome, further studies should allow us to identify the regions and assess the influence of RNA sequence and structure on these biological properties.

We thank Louise Pape, Cliff Lawson and Edward Pelle for technical assistance, and Drs K. H. Fernow and T. O. Diener for inocula from the various PSTV isolates studied. Research carried out at The Rockefeller University was supported in part by a grant to E.D. from the NSF, grants to H.D.R. from the NSF, the American Cancer Society, and from the NCI. Research at Cornell University was supported in part by a grant from the National Institute of Allergy and Infectious Diseases.

Selecting *Rhizobium* for acid, infertile soils of the tropics

AN increase in beef cattle production on the 350 million hectares of acid, infertile savannahs of tropical South America would have a major impact on world food production. Production in these regions is limited by the inadequate nutritional value of the native vegetation, and legume-based pastures are now being introduced[1] to raise the protein content of available forage. However, to obtain full benefit from biological nitrogen fixation through nodulated legumes it is necessary that the introduced legume form an effective symbiosis with *Rhizobium*. The low *p*H, limited availability of phosphorus, and very high levels of aluminium and manganese in these soils, are likely to affect nodulation and nitrogen fixation. It is therefore essential that strains of *Rhizobium* adapted to acid conditions are used. Alkali production by rhizobia from tropical legumes and the consequent rise in *p*H of test media has made the development of a simple test to select such strains difficult[2]. We report here that interference from alkali production can be eliminated by minor changes in the screening medium. This finding challenges the view that alkali production is a distinguishing characteristic with ecological significance[3], and is also a starting point for detailed study of the effects of acidity and related factors on growth of *Rhizobium*.

In an evaluation of 50 *Rhizobium* strains (from soils ranging from *p*H 4.5 to 9.0) isolated from nodules obtained from *Stylosanthes capitata*, *S. guianensis* and *S. hamata* we observed marked differences between strains in their ability to grow in two yeast–mannitol (YM) media differing in *p*H. Strains fell into one of three categories: 19 grew only in the standard YM medium of *p*H 6.8–7.0; 2 grew only in an acidified medium (adjusted to *p*H

4.5 with 0.1 M HCl); and 29 grew in both media. However, media which were acid initially had a final *p*H in the range 7 to 8 due to an alkalising effect which is claimed to be a differentiating characteristic of slow-growing tropical rhizobia[3]. Therefore, growth could indicate either genuine ability to multiply at low *p*H or capacity to progressively increase the *p*H of the medium to an adequate level for growth. A stable acid medium is needed that selects specifically for the former character as strains which grow as a result of influencing their environment during the test are unlikely to be successful in more highly buffered acid soils.

A range of media differing in composition and *p*H was evaluated as substrate for the growth of two strains of contrasting origins (acid soil, Llanos Orientales, Colombia, *p*H 4.5 compared with alkali soil, near Kingston, Jamaica, *p*H 8.5). The strain of alkali soil origin grew in media of initial *p*H 7 and *p*H 8.5 but not in a medium of *p*H 4.5. The strain of acid soil origin grew best in the medium of *p*H 4.5, made little growth at *p*H 7 and even less at *p*H 8.5. Growth of the acid soil origin strain was equally good irrespective of whether the medium was acidified using hydrochloric acid, sulphuric acid or citric acid. It also grew satisfactorily in media incorporating other acidity stresses, that is, low P (10 μM), high Al (50 μM), low Ca (50 μM), and high Mn (200 μM). Growth of ***Rhizobium*** in acidified media incorporating mannitol, the standard carbon source recommended for culturing rhizobia, raised the *p*H from 4.5 to approximately 7.5. However, in acidified media in which arabinose, or alternatively galactose, was substituted for mannitol, the *p*H decreased slightly (to 3.8) yet growth (turbidity/absorbance) was essentially the same as in media incorporating mannitol. Previous attempts to stabilise culture media at acid *p*H for growth of ***Rhizobium*** by using buffers have proved unsatisfactory[4]. Other reports concerning optimal *p*H for growth of slow-growing rhizobia[5,6] and utilisation of carbohydrates[7] have referred to initial *p*H values. Final *p*H values have been reported for growth in a range of carbon sources but from an initial *p*H of approximately 7 (ref. 8).

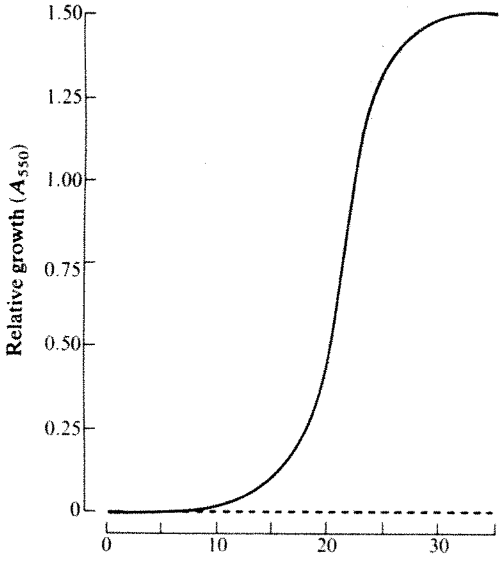

Fig. 1 Relative growth of *Rhizobium* strains CIAT 1460 (solid line), originating from an acid soil (*p*H 4.5), and CB 2126 (dashed line), from an alkali soil (*p*H 8.5), in a defined, acid medium (initial *p*H 4.2).

Table 1 Liquid medium for selecting acid-adapted strains of *Rhizobium*

Addition	Quantity added
KH_2PO_4	68 mg
K_2HPO_4	87 mg
$CaCl_2 \cdot 2H_2O$	39.4 mg
$MgSO_4 \cdot 7H_2O$	74 mg
Fe^{3+}Na EDTA	36.8 mg
$MnCl_2 \cdot 4H_2O$	0.49 mg
$ZnSO_4 \cdot 7H_2O$	0.29 mg
$CuCl_2 \cdot 2H_2O$	43 μg
$Na_2MoO_4 \cdot 2H_2O$	12 μg
$CoCl_2 \cdot 6H_2O$	1.2 μg
Sodium glutamate	220 mg
*Thiamine	100 μg
*Biotin	250 μg
Arabinose	10 g
Distilled water	to one litre

Acidified with 0.1 M HCl (before autoclaving).
* Filter sterilised and added after autoclaving the medium.

Growth of ***Rhizobium*** was quantified for a defined basal mineral salts liquid medium (Table 1) which was one of the media used previously. Cultures were incubated at 25–28 °C and aerated by shaking. Growth, both as optical absorbance at 550 μm and as viable cell number, and *p*H were determined over a period of 33 d in media which differed only in their carbon source (mannitol or arabinose). In both media, the acid soil origin strain CIAT 1460 showed exponential growth (Fig. 1), increasing from an inoculum of 7×10^3 to 1×10^9 viable cells per ml whereas the number of viable cells per ml of alkali soil origin strain CB 2126 diminished from 4×10^4 to 2×10^2. Growth of the acid soil strain in mannitol medium was associated with a substantial *p*H rise (Fig. 2); in arabinose medium, however, the *p*H declined from 4.2 to 3.9. Growth (viable cell number) of CIAT 1460 did not differ significantly in the two media.

The finding that some strains of ***Rhizobium*** grow much better at *p*H 4.5 than in neutral media is contrary to the commonly accepted view that ***Rhizobium*** has a *p*H growth optimum of ~7 (refs 9, 10). It also helps explain why attempts to isolate *Rhizobium* from nodules of *Stylosanthes* (especially *S. capitata*) growing in soils at *p*H 4.5–5.5 have been unsuccessful—the routine isolation medium has a *p*H 6.8–7.0. In addition it suggests that the standard practice of searching for acid stress tolerant ***Rhizobium*** in existing collections of strains that were originally isolated onto routine non-stress media may not be successful.

Now that this medium is available it will be possible to test the effects of characteristic acid-soil conditions, such as high aluminium content, on ***Rhizobium***. Comparison of strains in the early phase of their growth before a change in the *p*H of the

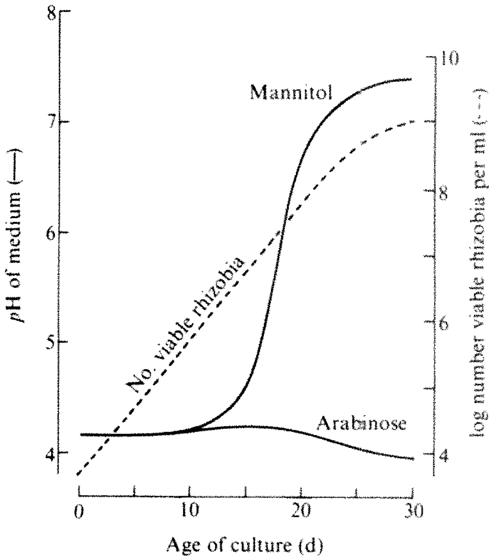

Fig. 2 The *p*H changes during culture of *Rhizobium* strain CIAT 1460 in defined liquid media containing either the standard carbohydrate source mannitol, or an alternative source, arabinose. Rhizobia multiplied at the same rate in both media from an initial viable cell number of 7×10^3 to 1×10^9 cells per ml.

medium can be detected[7] has the disadvantages that strain differences have not become fully pronounced and that the growth must be estimated by the extremely tedious viable count method. Availability of an acid medium in which the *p*H does not rise permits a simple test in which attainment of visual turbidity indicates ability to grow at low *p*H.

Finally, our demonstration that alkali production by slow-growing, tropical-type rhizobia is dependent on the carbohydrate of the culture medium reopens the question of whether these microorganisms actually produce alkali in the rhizosphere of their host and whether an ecological role should have been attributed to the process[3].

Inactivation of restriction endonuclease *Bam*Nx after infection with phage ϕNR2

A HOST-CONTROLLED restriction–modification system[1-3] is a means of protection by a host against attacks of bacteriophages. Recently, coliphage T3 and T7 have been found to overcome[4-7] the host-controlled restriction–modification systems of their host strains *Escherichia coli* B and K, but details of the mechanism are not well understood at present. We have found that a *Bacillus subtilis* phage ϕNR2rH, a mutant of ϕNR2 (ref. 8), also has the ability to overcome the restriction–modification system of *B. amyloliquefaciens* strain N, and detected a *Bam*Nx inhibitor in cells infected with ϕNR2rH.

Shibata and Ando found two different restriction endonucleases[9-11], *Bam*NI (*Bam*NI cleaved DNA in the same nucleotide sequence as *Bam*HI (refs 12, 13)) and *Bam*Nx in the strain N. *Bam*Nx is a typical type II restriction endonuclease. The phage ϕNR2 and its host *B. subtilis* PS9 (derivative of *B. subtilis* Marburg strain sensitive to phage SP10 and ϕNR2) were isolated by Yajima *et al.*[8,14]. Since ϕNR2 DNA is completely insensitive to *Bam*NI, the phage ϕNR2 can form plaques normally on both PS9 and *B. amyloliquefaciens* strain H. ϕNR2 (grown on PS9) however, forms plaques on strain N at a frequency of about 4×10^{-4}. Initially we thought that the phage ϕNR2 was restricted by *Bam*Nx of strain N and that the survived phages would be modified. One clone, isolated from the plaques on strain N, was no longer restricted by this strain. Nevertheless, the DNA, prepared from phage particles grown on strain N, was still cleaved by *Bam*Nx (Fig. 1). These results suggested that this mutant has the ability to overcome the host-controlled restriction–modification system of strain N. The mutant was designated as ϕNR2rH because it formed rapid lysis-type plaques on strain H. ϕNR2rH was inactivated by anti-ϕNR2 serum, and its DNA gave the same *Eco*RI cleavage pattern as that of ϕNR2 DNA (data not shown), indicating that ϕNR2rH is a spontaneous mutant of ϕNR2.

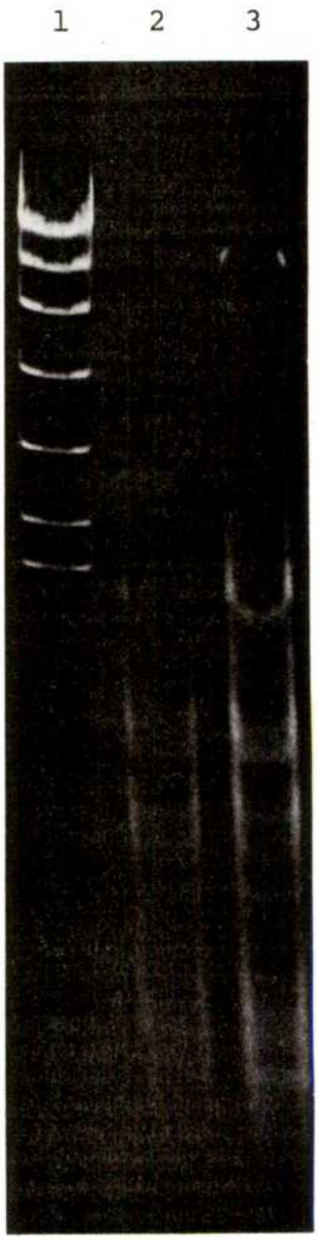

Fig. 1 Cleavage of DNAs of ϕNR2 (grown on PS9) and ϕNR2rH (grown on strain N) with endonuclease *Bam*Nx. Each DNA (1 μg) was reacted with *Bam*Nx in 20 μl of 20 mM Tris-HCl buffer (*p*H 7.5) containing 0.2 mM EDTA, 15 mM $MgCl_2$ and 5 mM 2-mercaptoethanol at 37 °C for 60 min. Cleaved DNAs were adjusted to 8% glycerol and 0.02% bromophenol blue and heated for 2 min at 60 °C. The samples were applied to 0.8% Agarose (Seakem) slab gel (15 × 15 × 0.3 cm). Electrophoresis was carried out at room temperature for 2.5 h at a constant current of 90 mA. The gel was stained with ethidium bromide and photographed with short-wave ultraviolet light. Löening's buffer[15] (36 mM Tris-HCl, *p*H 7.7, 30 mM NaH_2PO_4, 1 mM EDTA) was used for electrophoresis and staining[16]. 1, *Bam*NI fragments of *B. subtilis*-phage ρ11C3a DNA as standard markers (see Fig. 3 in detail); 2, ϕNR2 (grown on PS9) DNA cleaved with *Bam*Nx; 3, ϕNR2rH (grown on strain N) DNA cleaved with *Bam*Nx.

ϕNR2rH was not restricted by strain N, whereas its DNA was cleaved by *Bam*Nx from strain N, *in vitro*. We therefore examined whether or not the activity of *Bam*Nx still remains in N cells infected with ϕNR2rH. Crude extract was prepared from phage-infected cells by the following procedure . Cells of strain N were infected with ϕNR2rH at a multiplicity of five when the number of cells became approximately 1.5×10^8 ml^{-1} in L-broth at 37 °C with shaking. The infected cells were collected 15 min after infection and stored at −20 °C. These cells were then thawed, suspended in 20 mM Tris-HCl buffer (*p*H 7.5) containing 5 mM MgCl$_2$, 0.2 mM EDTA and 5 mM 2-mercaptoethanol, and sonicated for 15 min in an ice-water bath. After removal of the cell debris by centrifugation at 80,000*g* for 90 min at 4 °C, 5% streptomycin sulphate solution was added gradually, to give a final concentration of 1%. The suspension was centrifuged and the supernatant was dialysed at 4 °C overnight against the 20 mM Tris-HCl buffer described above. The precipitate which appeared during dialysis was removed by low-speed centrifugation. The final supernatant was the crude extract used in this study. Crude extracts were also prepared from ϕNR2-infected and uninfected N cells, as was the ϕNR2rH-infected cell extract. We could detect *Bam*Nx activity in the extracts from ϕNR2-infected and uninfected cells but not in the extract from ϕNR2rH-infected cells (data not shown). We concluded, therefore, that ϕNR2rH infection caused the inactivation of *Bam*Nx.

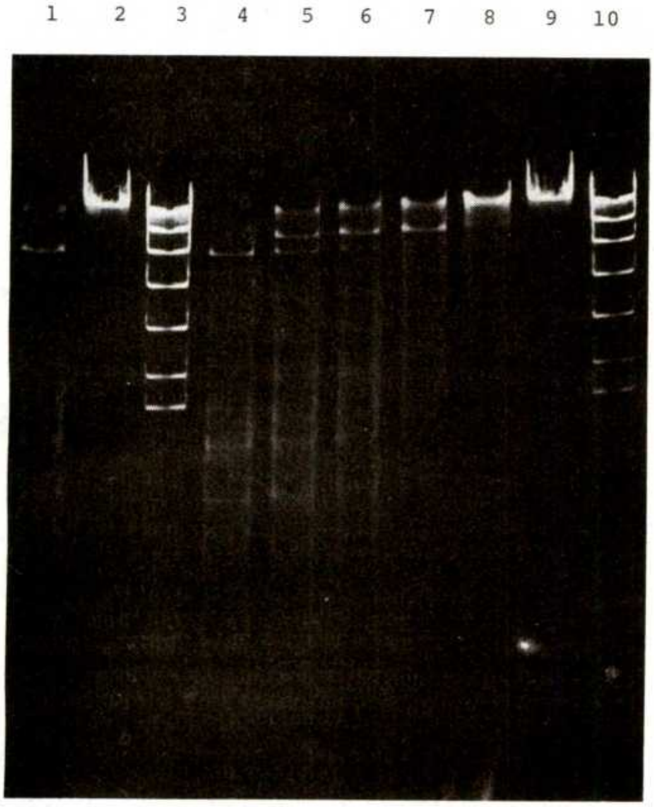

Fig. 2 Detection of *Bam*Nx inhibitor in the crude extract from ϕNR2rH-infected N cells using ϕNR2rH DNA as the substrate of *Bam*Nx. Purified *Bam*Nx was preincubated with various amounts of the crude extract, prepared as described in the text, in 50 μl of 20 mM Tris-HCl buffer (*p*H 7.5) containing 0.2 mM EDTA, 15 mM MgCl$_2$, 5 mM 2-mercaptoethanol at 37 °C for 15 min. After this treatment, 2.5 μg of ϕNR2rH DNA extracted from purified phage particles grown on strain N were added, incubated for 60 min at 37 °C and 30 μl of each sample were applied to electrophoresis for the analysis of the remaining *Bam*Nx activity. Electrophoresis was carried out as described in Fig. 1. *Bam*NI fragments of *B. subtilis*-phage ρ11C3a DNA were used as standard markers (see Fig. 3 in detail). 1, Remaining activity of *Bam*Nx after the preincubation with 25 μl of the crude extract (about 7 mg protein per ml) from uninfected N cells; 2, untreated ϕNR2rH DNA; 3, *Bam*NI fragments of ρ11C3a DNA; 4–8, inactivation of *Bam*Nx by the preincubation with the crude extract from ϕNR2rH-infected N cells. Purified *Bam*Nx was preincubated with 0 μl (4), 1 μl (5), 3 μl (6), 10 μl (7) and 25 μl (8) of the crude extract from ϕNR2rH-infected N cells (about 8 mg protein per ml). 9, untreated ϕNR2rH DNA; 10, *Bam*NI fragments of ρ11C3a DNA.

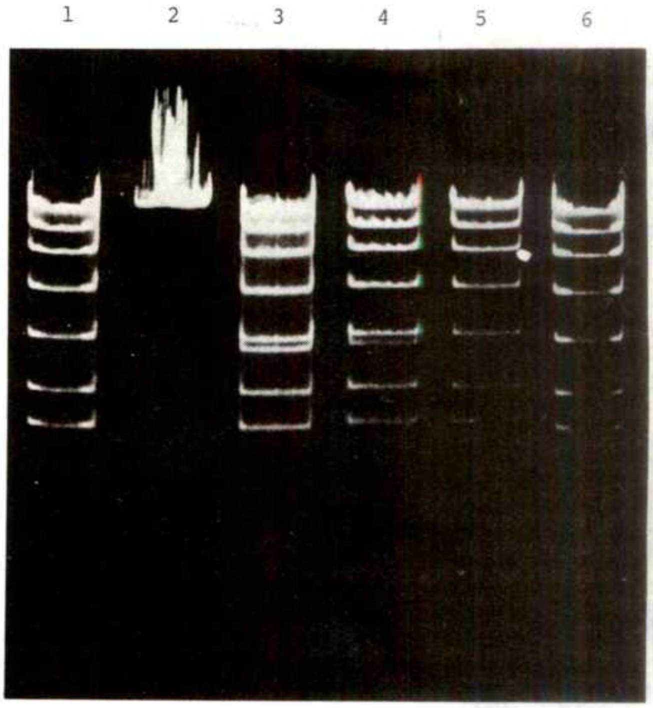

Fig. 3 Detection of *Bam*Nx inhibitor using ρ11C3a DNA as the substrate of *Bam*Nx. The same crude extracts as described in Fig. 2 were used. *B. subtilis*-phage ρ11C3a DNA generates 10 fragments by *Bam*NI (or *Bam*HI) cleavage, and 2 fragments by *Bam*Nx cleavage (Kawamura and Ito, in preparation). *Bam*NI fragments were designated *Bam*NI A–J in order of decreasing size. *Bam*Nx cleaves *Bam*NI A fragment and a new DNA band appears between the *Bam*NI E and F fragments by Agarose gel electrophoresis after cleavage with both *Bam*NI and *Bam*Nx. It is thus possible to determine the activity of *Bam*NI and/or *Bam*Nx using this DNA as substrate. The preincubation of purified *Bam*Nx with the crude extract was performed in the same conditions as described in Fig. 2. Electrophoresis was carried out as described in Fig. 1. 1, *Bam*NI fragments of ρ11C3a DNA; 2, untreated ρ11C3a DNA; 3, fragments of ρ11C3a DNA generated by purified *Bam*NI and purified *Bam*Nx; 4, remaining activity of *Bam*Nx after the preincubation with 25 μl of the crude extract from uninfected N cells; 5, inactivation of *Bam*Nx by the preincubation with 25 μl of the crude extract from ϕNR2rH-infected N cells. 4 and 5 also show that *Bam*NI activity still remains in ϕNR2rH-infected N cells. 6, *Bam*NI fragments of ρ11C3a DNA.

*Bam*Nx, purified according to the method described by Shibata and Ando[11], was preincubated for 15 min at 37 °C with various amounts of the crude extract, and the remaining activity of *Bam*Nx was determined by Agarose gel electrophoresis. *Bam*Nx activity was seriously inhibited by the preincubation with crude extract prepared from ϕNR2rH-infected N cells (Figs 2 and 3). This suggested that the *Bam*Nx inhibitor appears after the ϕNR2rH infection, and that this *Bam*Nx inhibitor is responsible for overcoming the host-controlled restriction–modification system of strain N.

In order to reveal the molecular function of the *Bam*Nx inhibitor in detail, it will be necessary to purify it, but our preliminary data indicate that it is proteinous and inhibits *Bam*Nx specifically.

Phage ϕNR2rH, like T3 and T7, has the function of overcoming the host-controlled restriction–modification system. The restriction endonucleases overcome by T3 and T7 belong to type I. Phage ϕNR2rH may be the first example of a shape overcoming the type II restriction endonuclease of its host strain. A similar phenomenon might be found in further studies, and if so, it would have biological importance in host–parasite interactions.

Dependence of protein synthesis on RNA synthesis during the early hours of germination of wheat embryos

WHEAT EMBRYO germination is characterised by an increase in fresh weight during the first 40 min of imbibition, followed by a lag period of 5 h and finally, a phase of cell elongation during which fresh weight increases at a sustained rate[1]. An essential step in seed germination is *de novo* synthesis of proteins, but for the first 40 min it is mediated by preformed mRNA transcribed during embryogenesis[2]. Previous reports have shown that although there is a 2.5–3-fold increase in the relative rate of protein synthesis during the lag period (40 min–5.5 h)[3], there is no appreciable change in the rate of RNA synthesis[4-7]. With the recently developed sensitive assays for ribonucleoside triphosphates[8,9], the rate of RNA synthesis and its mode of regulation in early germination of wheat embryos was re-examined[10]. In contrast to previous findings[4-7], our results clearly show a two- to threefold increase in the rate of RNA synthesis during the lag period of wheat embryo germination. This increase in RNA synthesis could conceivably account for the threefold increase in the rate of protein synthesis[4] and raises the possibility that protein synthesis may depend on RNA synthesis after the first 40 min of germination. We describe here experiments undertaken in wheat (*Triticum aestivum* L.) embryos to study the effect of inhibition of RNA synthesis on the rate of protein synthesis. Our data suggest that protein synthesis depends on RNA synthesis, and that the substrate level of mRNA is not a rate-limiting determinant for protein synthesis during the early hours of germination.

Fig. 1 Isolated wheat embryos (100 μg) were germinated for 3 h in the presence or absence of α-amanitin. Ribosomes were isolated as described by Spiegel *et al.*[5]. Four A_{260} units of ribosomes were separated on a 17–42% linear sucrose gradient with a 0.5 ml sucrose (1.8 M) pad in a Beckman SW 50.1 rotor by centrifuging at 49,000 r.p.m. for 40 min. *a*, control; *b*, treated with 2 $\mu g\,ml^{-1}$ of α-amanitin; *c*, treated with 10 $\mu g\,ml^{-1}$ of α-amanitin.

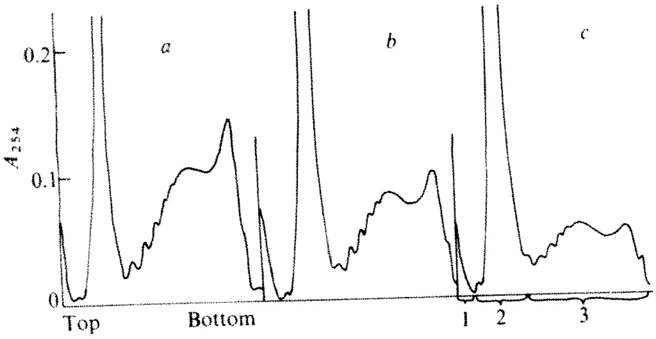

Table 1 Effect of α-amanitin on RNA(*a*) and protein (*b*) synthesis

a

a, Isolated wheat embryos were germinated as described previously for 3 h in the presence or absence of α-amanitin[10]. After 3 h of germination, 10 μCi of $[5\text{-}^3\text{H}]$uridine was used to label 50 mg of isolated wheat embryos for 30 min. The 5% trichloroacetic acid-insoluble material was prepared as described previously[10]. 50 mg of germinated wheat embryos were ground with 0.4 ml of high salt buffer (1 M KCl, 0.1 M Tris-HCl (*p*H 7.6) and 10 mM EDTA) with a mortar and pestle. 2 ml of 1% SDS buffer (5 mM EDTA, 10 mM Tris-HCl (*p*H 7.6) and 1% SDS) was then added to the extract, mixed well and extracted twice with 3 ml of water-saturated chloroform–phenol (1 : 1, v/v). The aqueous phase was adjusted to 0.2 M ammonium acetate and the RNA was precipitated by 2 volumes absolute ethyl alcohol (18 h, −20 °C). The precipitate was washed 3 times with 2 M LiCl, twice with 70% aqueous ethyl alcohol, dried and dissolved in 2 ml of sterilised water. The total RNA (6.25 μg) was translated in a wheatgerm extract S30 system[15]. Ribosomes were obtained from 100 mg of isolated wheat embryos germinated for 3 h as described by Spiegel *et al.*[5]. The ribosomal pellet was suspended in 2 ml of 1% SDS buffer and then mixed with 1 ml of regular buffer (5 mM EDTA and 10 mM Tris-HCl, *p*H 7.6). 400 μl of high salt buffer were added to the ribosome suspension. The resulting precipitate was removed by centrifugation. 3 ml of water-saturated chloroform–phenol were used to extract the aqueous phase. The RNA was prepared as described before. The wheatgerm extract S30 was used to translate 5 μg of ribosome-associated mRNA. *b*, After 3 h of germination, the embryos were labelled with 20 μCi of L-$[4,5\text{-}^3\text{H(N)}]$leucine for 30 min. The 5% trichloroacetic acid-homogenate was prepared as described previously[10], except that it had been incubated at 90 °C for 15 min. The polysome content was obtained from Fig. 1 by measuring the area of the polysome region from absorbance compared with the fraction plot following sucrose gradient centrifugation. Ribosomal fractions were prepared as described above. Excess wheatgerm extract S100 (5 μl) was used for the completion of nascent peptidyl chains present in 0.16 A_{260} units of ribosome in the presence of 8 μM pactamycin.

After 3 h of germination, concomitant decreases in RNA and protein synthesis were observed in isolated wheat embryos treated with α-amanitin (Table 1, column 3). Measurements of the fractionation of ribosomes isolated from α-amanitin-treated samples on a 17–42% sucrose gradient revealed a decrease in polysomes and an increase in monosomes (Fig. 1). With α-amanitin at 2 $\mu g\,ml^{-1}$ and 10 $\mu g\,ml^{-1}$, the polysome content was depressed by 21% and 46%, respectively (Table 1*b*, column 4). Active ribosomes were quantified by allowing the nascent peptidyl chains of active ribosomes to complete polypeptide

0028–0836/79/0277—0066$01.00

synthesis in the presence of the initiation inhibitor, pactamycin. The treatment of α-amanitin at $2\ \mu g\ ml^{-1}$ and $10\ \mu g\ ml^{-1}$ caused a decrease in the amount of active ribosomes by 18% and 44%, respectively (Table 1*b*, column 5). The possibility of a direct effect by α-amanitin on protein synthesis was eliminated by an *in vitro* study with a cell-free wheatgerm translation system (data not shown).

α-Amanitin probably inhibits the synthesis of mRNA which in turn may affect either the substrate level of mRNA or the cellular content of an essential factor(s) required for protein synthesis. After 3 h of germination, the cellular level of total mRNA was 22% and 46% lower than the control sample when treated with α-amanitin at $2\ \mu g\ ml^{-1}$ and $10\ \mu g\ ml^{-1}$, respectively (Table 1*a*, column 5). The amount of mRNA actually associated with ribosome in α-amanitin-treated samples was decreased to a lesser extent. When $2\ \mu g\ ml^{-1}$ of α-amanitin was used in the incubation, the amount of ribosome-associated mRNA decreased by only 9% (Table 1, column 7). Such a small decrease in the ribosome-associated mRNA cannot fully account for the 40% inhibition of protein synthesis (Table 1*b*, column 3) and the 20% depression of polysome content (Table 1*b*, column 4). Therefore, the substrate level of mRNA does not seem to be the rate-limiting determinant for protein synthesis.

No obvious changes in the polysome profile were observed following treatment with α-amanitin (Fig. 1). This observation would suggest that normal loading of ribosomes on the mRNA can proceed once the mRNA is 'activated' for protein synthesis. A reduced initiation efficiency in protein synthesis has been observed in other cell systems in resting compared with proliferating cultures[11,12]. It is possible that the formation of the first peptidyl bond is required by the essential factor(s), as the first dipeptide synthesis is a unique step in protein synthesis[13]. It has also been reported that protein synthesis is not regulated by the supply of mRNA in oocytes of *Xenopus laevis*[14].

We thank Dr Abraham Marcus for the isolated wheat embryos. This research was supported by a grant from the NSF.

MHC matching shows that at least two T-cell subsets determine resistance to HSV

DISTINCT T-cell subsets recognise antigens in association with different major histocompatibility complex (MHC) products, and this provides a means of identifying the subsets which operate in protective immunity against pathogens. Thus, cytotoxic T cells (T_C) recognise antigen in association with products of the K and D regions of the H–2 complex of the mouse; and because protection against lymphocytic choriomeningitis[1], ectromelia[2] and influenza[3] requires compatibility at K or D in adoptive transfer experiments, it follows that the subset mediates protective immunity against these viruses. I-region compatibility requirements have not hitherto been observed in viral infections, but are necessary for protection against the intracellular parasite *Listeria monocytogenes*. This suggests that T helper cells (T_H) and/or the lymphocytes responsible for delayed hypersensitivity and lymphokine release may be involved[4] (these lymphocytes can provisionally be included within the T_H subset). Adoptive transfer studies in mice have clearly established a major role for T lymphocytes in recovery from infection with herpes simplex virus (HSV-1)[5–7]. The T-lymphocyte subclass or classes responsible for this protection are not known. *In vitro* cytotoxic T cells (T_C)[8], and their primed precursors[9] can be obtained from HSV-1 infected mice. The present study indicates that immune protection against HSV-1 can be conferred by immune spleen cells possessing either I or K-D compatibility, and that long-lasting protection is conferred only by cells with I-region compatibility.

Table 1 H–2 compatibility required for immunological protection against HSV-1: adoptive transfer to AQR B mice

Donors (H–2 haplotype), no. and type of spleen cells transferred	Survival at 14 d	Survival at 60 d
AQR (qkkddd)		
5×10^7 normal	1/9	1/9
5×10^7 immune	11/11	11/11
$1–1.5\times10^7$ immune	10/12	10/12
5×10^6 immune	0/4	–
B10.BR (kkkkkk)		
5×10^7 normal	1/9	1/9
5×10^7 immune	9/9	9/9
$1–1.5\times10^7$ immune	3/12	3/12
B10.T(6R) (qqqqqd)		
5×10^7 normal	0/8	–
5×10^7 immune	7/10	2/10
$1–1.5\times10^7$ immune	4/11	0/11
B10.BR+B10.T(6R)		
$1.5\times10^7+5\times10^6$ immune	5/11	5/11
C57BL/6(bbbbbb)		
5×10^7 immune	2/10	2/10
$1–1.5\times10^7$ immune	0/8	–

Donor strains of mice (Table 1) were immunised initially by intraperitoneal injection of 10^5 plaque-forming units (PFU) of Kruger strain HSV-1, boosted with 10^7 PFU after 1 week and 10^6 PFU after 2 weeks (virus was grown on cell strain BHK-13, and stored at −70 °C at a concentration of 10^9 PFU ml^{-1}). After 10–14 d, pooled sera from each strain of donor mice consistently showed antibody in dilutions of 4×10^{-4} by a solid phase radioimmunoassay. At this time teased spleen cells were obtained aseptically, washed three times with a modified Eagle's medium and injected into recipients in the numbers indicated in Table 1. Recipients were 12–16-week-old AQR mice which had been adult thymectomised at 4–6 weeks of age, and at 8–10 weeks had been irradiated (750–800 R) and reconstituted with $1–2\times10^7$ AQR bone marrow cells following anti-Thy-1.2 and complement treatment ('B' mice).

Two days after spleen cell transfer, 2×10^6 PFU of HSV-1 were injected intraperitoneally; this was a quantity of virus found to be lethal for AQR B mice, which were themselves 100-fold more susceptible to the virus than normal mice of the same strain. Times of death were recorded and fell into two distinct groups. Mice dying less than 14 d after HSV-1 developed a progressive paralysis and findings typical of HSV

0028–0836/79/0277—0067$01.00

encephalitis[6]. A second group of mice died 30–60 d after HSV-1. Those mice surviving beyond 60 d were considered to have a lasting immunity.

As Table 1 indicates 5×10^7 syngeneic immune cells (AQR) and 5×10^7 immune cells with I-region compatibility (B10.BR) conferred a long-lasting protection; $1\text{–}1.5\times10^7$ AQR immune spleen cells were also protective, but this number of B10.BR cells were protective in only 3/12 mice; 5×10^7 immune spleen cells with K-D compatibility, B10.T(6R), were protective initially in 7/10 mice but only 2/10 mice survived 60 d; $1\text{–}1.5\times10^7$ B10.T(6R) immune cells were initially protective in 4/11 instances, but long-lasting immunity was not achieved in any mouse. An attempt at enhancing protection by combining immune cells from two strains of mice, one with I-region compatibility (1.5×10^7 B10.BR) and the other K-D compatibility (5×10^6 B10.T(6R)) was successful in only 5/11 mice; this effect was long lasting, but in numbers not significantly different from that obtained with B10.BR cells alone. Spleen cells from non-immunised donors and from an immunised strain without H-2 compatibility (C57BL/6) failed to provide protection. By contrast, 5×10^7 of C57BL/6 immune spleen cells provided 100% protection in 26 acutely irradiated, HSV-infected B6 mice (350–450 R); spleen cells from non-immunised C57BL/6 mice failed to protect (18/21 deaths in less than 14 d).

These results demonstrate the need for H-2 compatibility in immune protection against HSV-1 in adoptive transfer studies in mice. Immune spleen cells from a mouse strain with known high resistance to herpes infection C57BL/6 (ref. 10), and demonstrated capacity to protect acutely irradiated HSV-1-infected syngeneic mice, fail to protect in non-H-2-compatible recipients. The protection conferred by H-2-compatible immune spleen cells is mediated by T cells, as we have confirmed previous work[7] showing that treatment of the transferred cells with anti-Thy-1.2 and complement abolished their protective effect (data not shown).

T-cell recognition of both I and K-D coded self-markers seems to be important in immune protection against HSV-1 in mice. I-region compatibility confers a long-lasting protection, whereas K-D compatibility confers only a temporary protection in most animals. These findings are consistent with a role for both T_H lymphocytes and T_C lymphocytes in the immune response to this virus, and complete protection is provided by T_H lymphocytes alone in sufficient numbers. It might be argued that T_C lymphocytes may also have played a part in long-term protection, through differentiation of precursors in the thymus of the K-D-imcompatible host; however, this seems unlikely because such precursors are not known to occur among spleen cells. This is therefore the first demonstration that T_H cells may have a greater protective capacity than T_C in a virus infection. It should be emphasised that this study differs from the previous short-term studies using recoverable virus as an end point, which have demonstrated a need for K-D compatibility only. T_H cells may prove important in recovery from these infections, as *in vitro* experiments suggest[11]. The interpretation of our long-term effects are open to question because of the problem of reaction to the alloantigens, but the significant point is that long-term protection was in fact obtained. We think it unlikely that the long-term protection can be attributed simply to an allogeneic effect, not only because of its duration, but also because it was obtained with K-D-incompatible rather than I-incompatible cells.

T_H could be providing protection in several ways, including helping T_C precursors or B cells, the elaboration of lymphokines leading to the recruitment of other cells, and the direct activation of macrophages[4]. The importance of mature macrophages as effector cells in recovery from HSV-1 infections has been stressed previously[7,12,13]. Help for B cells in the production of anti-viral antibody is perhaps the most straightforward possibility; the fact that anti-Thy-1 treatment abolishes protection does not argue against this possibility, for such treatment would inactivate the helper cells known to participate in the secondary antibody response to HSV and other viruses[14]. The failure to achieve a protection comparable to that with syngeneic cells by a combination of two cell sources, one with I-region and the other with K-D-region compatibility suggests that compatibility may be required between T_H and T_C to achieve complete protection with low numbers of transferred immune cells.

Immune spleen cells recognising K-D-coded self-antigens only are also initially protective, strongly suggesting that T_C cells play a part in the immune response to herpes *in vivo* as well as *in vitro*[9]. The failure of such adoptively transferred mice to survive indefinitely may be due to eventual loss of specifically immune short-lived lymphocytes, although other mechanisms such as a graft-versus-host response could not be excluded in the present study.

HSV-1 was supplied by Dr D. Planterose, Beechams.

Evidence for a specific B27-associated cell surface marker on lymphocytes of patients with ankylosing spondylitis

THE strong association of HLA-B27 with ankylosing spondylitis (AS) as well as an increased frequency of B27 in other seronegative arthropathies is well documented[1–4]. Nevertheless, the significance and the molecular basis of this remarkable association is still unknown. Ebringer *et al.*[5–7] reported that *Klebsiella pneumoniae* was present in the faeces of patients with AS more frequently than in those of healthy controls, and that there seemed to be some cross-reactivity between HLA-B27-positive lymphocytes and *Klebsiella* antigen. It is possible, therefore, that an infectious agent, probably an enteric organism, is involved in the pathogenesis of AS. We have therefore decided to examine the *in vitro* proliferative responses of peripheral blood lymphocytes to *Klebsiella* and to several enteric organisms. To examine the possibility of cross-reactivity between B27 and *Klebsiella* antigen, we raised antisera in rabbits against various isolates of *Klebsiella* and tested the cytotoxicity of these antisera on lymphocytes of AS patients and of normal controls. The results presented here strongly suggest

Yersinia	0.69 (±0.02)	0.7 (±0.1)	0.72 (±0.01)	0.03	0.3	0.2
Phytohaemagglutinin	1.9 (±0.02)	1.8 (±0.03)	1.8 (±0.03)	1.23	1.1	1.0

The distribution of the stimulation indices for each antigen and each group of individuals was normalised by $\log_{10}$ transformation and the means of the $\log_{10}$ transformed values compared using the Student's *t* test (* $P<0.01$, † $P<0.001$). Peripheral blood lymphocytes were obtained from groups of B27-positive patients with ankylosing spondylitis (B27$^+$AS$^+$, $n=25$), B27-negative normal controls (B27$^-$AS$^-$, $n=37$) and B27-positive normal controls (B27$^+$AS$^-$, $n=13$). The cells were separated from heparinised blood by centrifugation in Ficoll–Paque (Pharmacia) for 25 min at 580*g*. The leukocyte band was removed and washed with RPMI 1640 (Flow) medium containing 2 ml heparin (1,000) units ml^{-1}), 10 ml 1M HEPES (Sigma) buffer, 5 ml L-glutamine (200 mM) and 2 ml penicillin–streptomycin (5,000 IU, 5,000 μg ml^{-1}; Flow) per 500 ml of RPMI medium. The leukocytes were suspended in RPMI medium containing 10% human AB serum and centrifuged for a further 10 min at 180*g*. The cells were then resuspended in RPMI medium containing 20% AB serum and adjusted to a cell concentration of 10^6 mononuclear cells per ml of medium. Bacterial suspensions were adjusted to either 10^6 (*Klebsiella*) or 10^9 (*Staphylococcus*, *Streptococcus*, *Yersinia* and *Shigella*) organisms per ml RPMI containing 20% AB serum. Lymphocytes (5×10^4 in 50 μl) were cultured in round-bottomed Linbro culture plates (Linbro) with 50 μl of the bacterial suspension (5×10^4 to 5×10^6 organisms) and 50 μl of RPMI containing 20% AB serum. All cultures were carried out in triplicate. In addition to the bacterial suspensions, the lymphocytes of each individual were cultured with phytohaemagglutinin (10 μg per well). The lymphocyte cultures were incubated at 37 °C for 6 d. On day 5, 1 μl of ^{3}H-thymidine (1 μCi) was added to each well and the cells collected about 24 h later, with a Skatron (Lierbyen) multiple cell culture collector. The radioactivity of the cells was measured in a liquid scintillation counter (Packard, TRI-CARB, model 2002). Results are expressed as stimulation indices: c.p.m. with antigen per c.p.m. without antigen.

Table 2 Antiserum to *Klebsiella* sp. (427) lyses lymphocytes of B27$^+$AS$^+$ patients but not of B27$^+$AS$^-$ or B27$^-$AS$^-$ healthy controls

Serum	Absorption	Target lymphocytes			
		B27$^+$AS$^+$	B27$^-$AS$^+$	B27$^+$AS$^-$	B27$^-$AS$^-$
Anti-B27	0	44	0	67	0
Anti-*Klebsiella* 427	0	69	1	11	10
Anti-*Klebsiella* 427	B27$^+$AS$^+$	13	nt	2	7
Anti-*Klebsiella* 427	B27$^+$AS$^-$	73	nt	10	3
Anti-*Klebsiella* 427	B27$^-$AS$^-$	64	nt	13	2
Anti-*Klebsiella* 468	0	11	12	6	13
Anti-*Klebsiella* 462	0	2	6	8	0
Anti-*Klebsiella* 433	0	8	7	12	3
Anti-*S typhimurium*	0	5	2	0	5
Anti-*S. typhi*	0	3	0	0	2
Anti-*Streptococcus* Group A	0	19	18	3	7
Anti-*Shig. dysenteriae*	0	2	0	4	5

Antisera to formalinised suspensions of various bacteria were tested on Ficoll-sedimented peripheral blood lymphocytes (see legend to Table 1) of B27$^+$AS$^+$ and B27$^-$AS$^+$ patients as well as B27$^+$AS$^-$ and B27$^-$AS$^-$ unaffected individuals in a ^{51}Cr release assay. About 10×10^6 lymphocytes were incubated in 1 ml of RPMI 1640 (Flow) containing 10% human AB serum and 100 μCi of ^{51}Cr (specific activity: 200–500 μCi per μg, Amersham) for 60 min at 37 °C. The cells were then washed twice with RPMI + 10% AB serum and resuspended at a concentration of 3×10^6 cells per ml. 100 μl of the ^{51}Cr-labelled cell suspension were added to 10×75-mm plastic tubes and incubated with 100 μl of antiserum at 24 °C for 30 min. Rabbit complement (100 μl) was then added to each tube and the incubation continued for a further 60 min. The cells were centrifuged at 2,000 r.p.m. for 15 min and 100 μl of the supernatant was counted in a Packard auto-gamma scintillation spectrometer. The amount of radioactivity in the samples was compared with radioactivity present in an equal volume of the supernatant from tubes containing cells in medium plus complement only, and with that present in tubes containing cells which were frozen and thawed three times. The results are expressed as the percentage of maximum ^{51}Cr released, which was calculated as follows:

$$^{51}\text{Cr realease \%} = 100\times\frac{\text{Radioactivity released by antiserum} - \text{radioactivity released in absence of antiserum}}{\text{Radioactivity released by frozen and thawed cells} - \text{radioactivity released in absence of antiserum}}.$$

The results shown are of a typical experiment on the cells of single individuals for each category. The antibacterial activity on the rabbit sera was demonstrated by the slide agglutination technique. Both the absorbed and unabsorbed antibacterial antisera were tested at a dilution of 1 : 8; anti-B27 antiserum was used undiluted. Anti-*Klebsiella* 427 antiserum was absorbed twice by mixing 100 μl of antiserum with 30×10^6 packed peripheral blood lymphocytes for 2 h at 24 °C The absorbed serum was centrifuged at 10,000 r.p.m for 30 min and diluted (1 · 8) with RPMI + 10% AB serum before testing.

that *Klebsiella* antigens cross-react with a gene product closely associated with HLA-B27 or with a *Klebsiella*-associated B27 antigen in AS patients.

As patients with AS have diminished T-cell responses to *Yersinia in vitro*[8], we wondered whether there was a similar impairment of *in vitro* T-cell proliferation in response to other bacterial antigens. Lymphocytes were obtained from B27-positive patients with definite ankylosing spondylitis (by Rome and New York criteria[9]) as well as from B27-positive and B27-negative healthy controls. Bacterial cultures were isolated from faecal samples (*Shigella flexner* and *Klebsiella*, isolate numbers 411, 427, 433, 462 and 468), a wound swab (*Staphylococcus* sp.) and a throat swab (Streptococcus sp.). *Yersinia enterocolitica* (NCTC no. 10598) was also used (American Type Culture Collection). Bacteria were killed by adding 0.25 ml of 40% formaldehyde to a 20-ml suspension of the organisms (10^9–10^{10} per ml) in nutrient broth. The formalin-killed bacteria were washed twice with sterile 0.9% NaCl and stored at −20 °C.

Table 3 Lymphocytotoxic activity of Anti-*Klebsiella* 427 antiserum for lymphocytes from AS patients and from normal controls

Diagnosis	B27 positive	No. positive/no. tested
Definite AS	Yes	21/23
Probable AS	Yes	3/3
Definite AS	No	0/3
Normal	Yes	0/13
Normal	No	0/22

Diagnosis was based on Rome and New York criteria.

The data in Table 1 show that B27-positive patients with AS as well as B27-positive and B27-negative healthy controls respond equally well to phytohaemagglutinin *in vitro*. Similarly, the responses of individuals, in all three groups, to *Staphylococcus*, *Streptococcus*, *Y. enterocolitica* and *Shig. flexner* are not significantly different. Commercially obtained preparations of *Salmonella tryphimurium* H specific and *S. typhi* H (Wellcome) failed to stimulate the lymphocytes of any of the individuals tested (data not shown). By contrast, B27-positive individuals affected with AS have a significantly lower *in vitro* responsiveness to *Klebsiella* (isolates 411, 427, 433, 462 and 468) as compared with B27-positive and B27-negative healthy controls. These observations, together with those of Ebringer *et al.*, suggest a possible cross-reactivity between *Klebsiella* antigens and HLA-B27, or the product of a closely linked gene. Alternatively, the lower lymphocyte responses to *Klebsiella* in AS patients may reflect an impaired processing of antigen by macrophages or the production of suppressor cells and/or suppressor factors by the lymphoid cells of affected individuals. These possibilities are now being studied.

In an attempt to gather further information on a possible cross-reactivity between *Klebsiella* and B27, we raised antibodies in rabbits to formalin-killed faecal isolates of *Klebsiella* (427, 433, 462 and 468) and to formalinised suspensions of *S. typhimurium* H specific and *S. typhi* H.

Rabbits (3–5 kg) were injected intravenously in the marginal ear vein with about 10^9 formalin-killed bacteria in normal saline (2 ml). Two weeks later, the animals received 10^9–10^{10} organisms in 2 ml of complete Freund's adjuvant (Difco) intramuscularly into multiple sites in the thigh and the nuchal skin. After 10–14 d the rabbits were boosted intravenously with 1 ml of bacterial suspension (10^8–10^9 organisms) in normal saline. Two weeks after the last injection, they were bled and the serum stored at −20 °C. In some cases the rabbits were boosted intravenously at 2- to 3-weekly intervals (for periods up to 6 months) with about 10^8 organisms in 1 ml saline, and bled 1 week after each injection.

Table 2 shows the results of a typical experiment on the cells of single individuals for each category. The data indicate that an antiserum to *Klebsiella* 427 lyses the lymphocytes of B27-positive patients with AS but not those of B27-negative individuals with active disease. By contrast, the lymphocytes of B27-positive and B27-negative unaffected individuals are not lysed by an antiserum to *Klebsiella* 427. Furthermore, the cytotoxic activity of antiserum 427 may be removed only by lymphoid cells from B27-positive patients with AS but not by lymphocytes from B27-positive or B27-negative normal controls. Antisera to other isolates of *Klebsiella* (468, 462 and 433) produced virtually no lysis of any of the target lymphocytes. Similarly, antisera to *S. typhimurium*, *S. typhi*, *Streptococcus* Group A and *Shig. dysenteriae* (both Wellcome) gave <20% ^{51}Cr release from the four categories of lymphocytes. Preliminary results (data not shown) indicate that antisera to *Y. enterocolitica* and *Staphylococcus* also fail to lyse the lymphocytes of affected and normal individuals. It is of interest that only one isolate of *Klebsiella* (427) gave a persistently high percentage ^{51}Cr release from the cells of B27-positive affected patients, whereas sera raised against the other three isolates produced only about 10% lysis. This suggests either that only some strains of *Klebsiella* cross-react with the putative B27-associated gene product in patients with AS or that *Klebsiella* 427 is more immunogenic in the rabbit than the other isolates tested. However, the latter possibility seems less likely, as rabbits boosted with isolates 468, 462 and 433 at 3-weekly intervals over a period of 4–6 months failed to produce detectable cytotoxic antibodies reactive with the lymphocytes of AS patients bearing the B27 allele.

Table 3 summarises the data on the reactivity of anti-*Klebsiella* 427 antiserum with lymphocytes from affected and normal individuals. The results strongly suggest cross-reactivity between some *Klebsiella* antigens and a gene product closely associated with HLA-B27 or possibly with genetically- or *Klebsiella*-modified B27 alloantigen complex in AS patients. The failure of anti-*Klebsiella* 427 antiserum to lyse cells from B27-negative AS patients suggests that B27 is an essential component of this hypothetical alloantigen–*Klebsiella* complex. Arnason *et al.*[10] have provided evidence that the predisposing determinant in AS may be either a modified B27 or a gene located on the Bf (properdin factor B) side of the HLA-B locus. This evidence was based on the rationale that if the predisposing locus were on the same side of the HLA-B locus as the Bf locus, B27-Bf haplotypes in those affected should be more uniform than in those not affected. On the other hand, if the B27 alloantigen predisposed directly there would be no reason to expect any difference in the incidence of the Bf alleles in the affected minority and the non-affected majority who carry the B27 allele. These authors found that patients with AS were Bf^s, whereas 23 of the controls (individuals with B27 but without symptoms) had Bf^f and 23 carried Bf^s.

In the murine system, the concept of 'altered self' has been extensively investigated by Zinkernagel *et al.*[11], using as their model the adoptive transfer of T-cell immunity to the bacterium *Listeria monocytogenes*. These workers showed that immunity to the bacterium can be successfully transferred only if the donor and recipient share a portion of the I (immune) region of the mouse H-2 complex. The T cells involved in this genetically restricted transfer seem to be specific either for a complex of 'self' in association with *Listeria* antigen or for bacterial antigen which is expressed on the cell surface and which is modified by I region-linked enzymes[12,13]. It remains to be determined whether a similar modification of the B27 allele, by an enteric organism, leads to the appearance of cytotoxic or suppressor T cells, and whether the activity of these cells is restricted by the human equivalent of the murine I region.

This work was supported in part by a grant from the National Health and MRC of Australia and the Clive and Vera Ramaciotti Foundations. We thank Ms Joan Yap and Dr Maureen Gapes for providing bacterial cultures used in this study, Carmel Edwards and Rosalind Dall for technical assistance, and the members of the NSW Branch of the Australian Rheumatism Association for allowing us to study patients in their care.

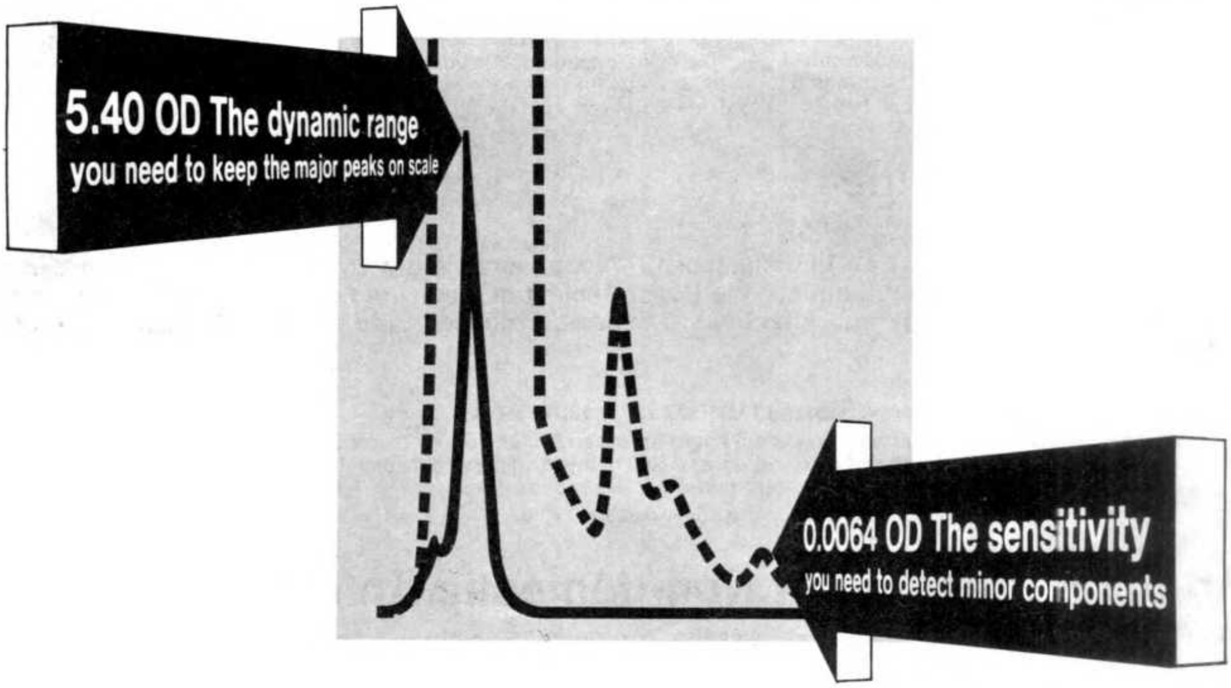
Now you can have it both ways!



5.40 OD The dynamic range
you need to keep the major peaks on scale
0.0064 OD The sensitivity
you need to detect minor components

Pharmacia Dual Path Monitor UV-2

has a unique flow cell with two optical path-lengths for new versatility in UV-monitoring.

- **Monitor absorbance quantitatively up to 20 OD units full scale with a sensitivity of 0.005 OD units full scale at the same time, in the same run.**
- **Monitor at 254 nm and/or 280 nm with two completely independent measuring systems.**

The Dual Path Monitor UV-2 has all the other features you expect of a high performance monitor: stability, cold room operation convenience and compact design. For less-demanding applications you can choose the Pharmacia Single Path Monitor UV-1 with a choice of 3 mm or 10 mm flow cell and operation at 254 nm or 280 nm.

Find out more about the practical advantages of column monitoring with the UV-2 and UV-1 Monitors. Ask about the Pharmacia Recorders too.

Measurement of Two-Phase Flow Parameters

G. F. Hewitt

December 1978, viii + 288pp., £10.80/$22.25 0.12.346260.6

Theoretical prediction of two-phase flow parameters is not generally possible, and therefore experiments and parametric measurements on two-phase flow systems are particularly important. However, numerous measurements have been made using the vast range of methods available, and the main function of this book is to assist the research worker in approaching the design of experiments by bringing together and classifying a very wide selection of material on measurements of two phase flow systems. The book is the first to deal exclusively with the subject.

Tropical Medicine

From Romance to Reality

Proceedings of a Conference 12-14 December 1977, sponsored jointly by the Royal Society of Medicine, London, the Wellcome Trust, London; the Royal Society of Medicine Foundation, Inc., New York; the National Institute of Allergy and Infectious Diseases, Bethesda; and John E. Fogarty, International Center, Bethesda.

edited by Clive Wood

January/February 1979, approx. 300pp., £13.20/$27.25 0.12.763360.X

This book — presenting the proceedings of an Anglo-American Symposium on Tropical Medicine — explores recent advances and considers future research in the prevention and care of the most prevalent communicable diseases that are related to the physical, social and economic environment of developing countries.

Published in New York by Grune & Stratton Inc. ISBN 0.8089.1141.4

Artificial Breeding of Non-domestic Animals

The Proceedings of a Symposium held at the Zoological Society in London, 7-8 September 1977

edited by P. F. Watson

December 1978/January 1979, approx. 300pp., £16.00 0.12.613343.3

This book gathers together in a single volume all that is presently known about the application of techniques of artificial breeding to non-domestic birds and mammals (including primates). Review chapters cover such aspects as semen collection, preservation and artificial insemination. The problems of the detection and induction of ovulation in non-domestic mammals are considered, and available techniques are reviewed.

Advances in Optical and Electron Microscopy

Volume 7

edited by R. Barer and V. E. Cosslett

January/February 1979, xii + 398pp., £19.60/$40.50 0.12.029907.0

This series attempts to cover all aspects of microscopy. In this volume two articles deal with problems arising from the study of moving objects, where the application of modern technology offers solutions to long standing problems. In the remaining articles the emphasis is on the physical principles of image formation and interpretation, such as the determination of the three-dimensional structure of macromolecules and the prospects for imaging single atoms. As with the previous volumes it is intended that this volume will be of interest to all those who use microscopy in both the biological and physical sciences.

This title was wrongly annotated in the December 7th 1978 issue

editor: J. R. Lagnado

Protein Phosphorylation

M. Weller

February/march 1979, 560pp.,/$58.00 0.12.85086.062.8

The early chapters describe and discuss the properties of the protein kinase and phosphatase enzymes. Other chapters deal with cyclic nucleotides, the action of hormones and protein phosphorylation; nonenzymic proteins which contain covalently bound phosphorus — phosvitin, casein, ovalbumin, fibrinogen; phosphorylation in relation to enzymic function; the role of phosphorylation in the control of the movement of ions; and protein phosphorylation in the nucleus; ribosomes; the cell membrane; the nervous system; various tissues; and viruses. Appendices describe techniques useful in the investigation of protein phosphorylation and the properties of phosphoproteins.

Sussex school of perception

A. W. Still

Perceptions and Representations: The Theoretical Bases of Brain Research and Psychology. By K. Oatley. Pp. 262. (Methuen: London, 1978.) £7.

THIS is a non-technical exposition of what might be called (though probably not by its members) the Sussex school of perception. In 1959 Stuart Sutherland, following Lashley, set out the problems posed for any theory of perception, and many of his colleagues at Sussex, including the author of this book, contributed to the solutions subsequently offered. The problems arose because the invariants of perception are not reflected by invariants in the stimulus. Objects look the same from different aspects, for instance, and wherever their image falls on the retina, while the information in the stimulus may be drastically incomplete, but still recognisable, as in a cartoon figure. The Sussex solution is found in artificial intelligence, a branch of computer science which has created programmes to compute "picture descriptions". These programmes are based upon the spatial configurations of the parts of the picture. Physically different stimuli (or cues, the term preferred by Dr Oatley), such as pictures of the same scene from different aspects, can give rise to similar descriptions or representations, and can thereby receive a common classification (but they may not, depending upon the "purposes" incorporated in to the programme; thus there is an attractive freedom from control by the stimulus). Dr Oatley gives a very readable account of these views and his book will be of great value to students of psychology, as well as to anyone interested in the way computer science has influenced psychology.

He begins historically by tracing the background in reflex or stimulus–response theory. It is this theory which poses the problems recognised by Lashley, and which are unanswerable in its own terms. To develop more appropriate terms, Dr Oatley explores the idea of "emergent" properties, through an account of his own work on feedback mechanisms in hunger and thirst. Properties of a system "emerge" when they cannot be deduced from the "fundamental units" of the system. Thus "properties of the feedback loop, control, regulation and entrainable oscillation clearly emerge as properties of organisation of processes in a feedback loop, not the individual processes themselves". Likewise, representational properties of mind emerge from physical elements, and artificial intelligence is an analogue of this process. By anchoring the concept to feedback loops and computer technology, "emergence" loses its mystical tinge, and mind can emerge respectably as matter organised in particular ways.

There are some clear acounts of artificial intelligence programmes, which are made accessible to the general reader without being watered down. These programmes can provide answers to the problems posed by stimulus–response theory, but do they provide an accurate model of visual perception? The evidence is sparse. True, one need only observe one's own thought processes to see that many perceptual tasks (such as Shepard and Metzner's experiments on puzzles the solutions of which involve imaging rotations of pictured solids) are solved by mental manipulations that can be incorporated into artificial intelligence programmes. But is all visual perception of this kind? The answer given by this book is "yes", perception involves the solution of a kind of puzzle, as retinal cues are incomplete, degenerate, often ambiguous, and sometimes downright misleading. But are they?

A questionable premise to the argument is that the eye is like a camera. This view is encouraged by, and encourages, experiments on perception of pictures (rather than objects) which have to be interpreted or classified. If the eye is a camera (albeit far from perfect) the picture is imaged on the retina, so the interpretation of the picture is, in effect, an interpretation of the retinal information. But what is the image and what is the retinal information, for a monkey leaping through trees or a skier weaving his way amongst trees? If the static image of a picture projected on to the stationery eye of a laboratory subject is degenerate, what can we say about the information on the retina of a moving animal? If the computations in the interpretation of a static image are complex, what are the computations necessary for an image that is rapidly changing? Much more complex, obviously, and yet visually guided movement, often rapid and of great refinement, occurs throughout the vertebrates, and therefore amongst animals that show little ability to interpret pictures.

Perhaps artificial intelligence will find the answer to this; it is trying, and the difficulties are admitted, though not seriously considered by Dr Oatley. But there is a powerful alternative answer to the problem, also not seriously considered in this book. J. J. Gibson has shown how the invariants of perception might, after all, be reflected in the visual environment, especially if we take account of (rather than forget) the movements of the retina with respect to that environment. This involves giving up the eye-camera analogy and considering the environment in relation to an animal moving through it. The retinal projections will be transformed over time, and it is in these transformations that, if Gibson is right, important invariants of perception can be found. This is a truly new theory, whereas the picture description theory, far from being a modern reaction to stimulus–response theory as suggested by Dr Oatley, has its roots in the long philosophical history of perceptions being constructed out of sensations, sense-data, stimuli, or sensory inputs. The famous straight stick which looks bent in water is the direct ancestor of all the puzzle stimuli and ambiguous figures with which psychology textbooks abound. In both cases it is falsely concluded that because stimuli are sometimes misleading they must always be so, at least potentially.

These are possible criticisms of the Sussex school of perception, which, being a school, is naturally one-sided, and whether the criticisms are valid or not Dr Oatley's book remains an excellent statement of this one-sided theory. The shakiness of the theory's foundations are all the better exposed by the clarity of the book, especially as Dr Oatley himself expresses doubts in the last chapter. The doubts are general, about science as a paradigm for psychology. It has great value, but is limited, and does not, for instance, help in the conduct of personal relations. A suggested answer to these doubts lies not in less but more reliance on computers, in the form of the "convivial computing" of Papert's LOGO project. The aim of the project is to use computers as teachers, whose pupils will remain free of the hangups and fears of appearing foolish that human teachers frequently inspire. It is an impressive project, but surely not an answer to Dr Oatley's doubts. Yet what answer could he give? Perhaps there is none within his framework of physiological psychology and artificial intelligence. This may explain his choice of a quotation from Doris Lessing at the beginning of the book: "And when a book's pattern and the shape of its inner life is as plain to the reader as it is to the author—then perhaps it is time to throw the book aside, as having had its day, and start again on something new." ☐

A. W. Still is Lecturer in Psychology at the University of Durham, UK.

Protein turnover

Protein Turnover in Mammalian Tissues and in the Whole Body. By J. C. Waterlow, P. J. Garlick and D. J. Millward. Pp. 804. (North-Holland: Amsterdam, New York and Oxford, 1978.) $120; Dfl.276.

THIS is a scholarly book in the best sense of that term: Professor Waterlow and his colleagues know the subject matter thoroughly, think very clearly and write very well. It is an expensive volume, but the isotopically labelled materials you need to study protein metabolism in the whole animal are also expensive, and most workers in this difficult field could easily save the cost of the book by reading it carefully, and then designing their experiments more wisely.

A frontispiece to the book indicates a "scientific heritage" going back to the mid-eighteenth century, but the genealogy is not one of orderly succession. In the late 1930s Schoenheimer and his colleagues made an astonishing leap forward by showing that metabolic precursors of all kinds, and in particular amino acids, could be labelled with stable isotopes, and thus that their metabolism in whole animals and tissues could be followed. The technical problems which had to be overcome to carry out this work were so great that no other laboratory was able to carry on the torch, but as a result of Schoenheimer's work, biological scientists learned to regard the body less as a fixed machine which ran on dietary fuel, and more like a military regiment in which the structure is in dynamic equilibrium with the fuel—in this case, the recruits.

It has proved unexpectedly difficult to continue where Schoenheimer left off. In the past 20 years techniques for measuring both radioactive and stable isotopes have greatly improved. It is deceptively easy to carry out tracer studies with labelled amino acids, but all too often they are impossible to interpret. Good tracer studies need many skills, and if the investigator's grasp of biochemistry or mathematics is inadequate, mere technical accuracy is of no use. This book concentrates on the biochemistry and mathematics.

The first section (164 pages) is on processes: a review of protein synthesis, degradation, and amino acid pools and transport. The key sentence is: "No measurement of the rate of incorporation of a labelled amino acid into protein can be used to calculate the rate of protein synthesis unless the specific activity of the free amino acid *at the site of protein synthesis* is also known." The second section, on methods (263 pages) starts with a useful introduction to mathematical models. Non-mathematicians should read this, as the study of anything so complex as whole body protein turnover requires models, and the more you know about their advantages and limitations the more likely you are to use them appropriately. The next chapters deal with methods for measuring protein turnover in the whole body by observing free amino acid labelling, in individual tissues by observing incorporation of label into tissue protein, and some special cases such as isolated perfused organs.

The remaining 323 pages of text on results draws heavily on the work done by Professor Waterlow and his colleagues, and this concludes with a most stimulating chapter on directions of future research. There are great technical and intellectual challenges for the next generation of research workers, in a field ready for a new explosion of knowledge. The problem is that the body is much less homogeneous than a military regiment, or even an army, as there are many more types of protein, with different kinetics, than there are types of soldier. For those who take up the challenge to discover how and why protein is turned over in tissues and animals (including man) this book is an excellent guide. **J. S. Garrow**

J. S. Garrow is at the Clinical Research Centre, Harrow, UK.

Seed development

Physiology and Biochemistry of Seeds in Relation to Germination. Vol. 1: Development, Germination, and Growth. By J. D. Bewley and M. Black. Pp. 306. (Springer: Heidelberg and Berlin, 1978.) DM90.

THE authors of this first volume of a two-volume work have concerned themselves with the physiology and biochemistry of seed development, germination and seedling growth. Approximately one-third of the book deals with seed structure and the development of the seed on the parent plant, and the remainder considers germination and seedling growth with particular attention to the mobilisation of reserves and the control of mobilisation. The interest in these topics and the use of seed and seedling material for much research in the plant sciences gives the subject of this volume a considerable importance for both teaching and research. Part of the work provides an excellent text for advanced students, one of its strongest points being its critical treatment of those dynamic aspects of seed development and germination, such as nucleic acid and protein synthesis and cereal aleurone layer studies, which have seen research work of a high quality in recent years. In areas in which there has been less distinguished recent work, such as the study of seed and seedling respiration and its control, the authors seem to have been rather less critical and somewhat over-generous in their assessment of the literature.

The authors' aim for comprehensiveness has resulted in the book having some rather dull sections, for example, on structure and on the chemistry and biochemistry of reserve materials, so that parts of the book have the character of a reference work, a feature of which is in keeping with the rather high price of the volume. Of course such a slim volume cannot really provide a comprehensive coverage of the subject and therefore each chapter is followed by some more general references so that the reader can fill out the topic. One vital and rather difficult topic has received very inadequate attention: the question of the measurement of germination, which receives less than two pages and exhortations to read the literature. Something more authoritative was called for here.

There are few errors in this attractively produced book. Most of the Tables and Figures have originated fairly directly from the literature and I found most value in those that had been specifically produced by the authors. In volume two I hope that the authors will give more scope to their illustrative talents and I look forward to the early appearance of this volume and to its treatment of the real problem, that of seed dormancy.

J. W. Bradbeer

J. W. Bradbeer is Professor of Botany at King's College, University of London, UK.

New from Elsevier

Geostatistical Ore Reserve Estimation

by MICHEL DAVID

Developments in Geomathematics, 2

Provides the reader with all the information necessary for implementing geostatistics in a mining company. Several computer programs are provided to solve the essential problems and it is explained how to actually generate a complete system for huge operations.

"... the first comprehensive textbook in English on the subject it certainly fills this need both for the student and the qualified mining engineer."
- World Mining

1977. 1st repr. 1978

Fluids in the Earth's Crust

Their Significance in Metamorphic, Tectonic and Chemical Transport Processes

by W. S. FYFE, N. J. PRICE *and* A. B. THOMPSON

Developments in Geochemistry, 1

Neither a traditional text on metamorphic petrology, nor a treatise on structural geology, this unique work transcends the conventional separation of these two fields by treating them in a unified way. The central theme is the role of fluids in tectonic, metamorphic and geochemical processes, and the text will undoubtedly find application and interest among a wide range of readers.

with the Canalco HSG Chamber for Horizontal Slab Gel Electrophoresis in agarose or polyacrylamide gel. Designed expressly for DNA research, the horizontal-format apparatus features a removable gel tray which provides support for low-mechanical-strength gels (0.18% agarose) during electrophoresis, staining, and photography. Gels are 19.5 cm wide by 40 cm long—long enough to resolve very complex mixtures in a single run. The chamber is capable of simultaneous analysis of 96 specimens; and it may be used preparatively, with gels up to 2.5 cm thick.

The Canalco HSG Chamber has numerous other features designed to help you perform electrophoresis effectively, including: Provision for buffer recirculation • Reusable gel wicks • Temperature control (up to +60°C for heat denaturation) • Safety interlock • Optional UV-transparent gel tray (for use with ethidium bromide or other fluorescent stains)

Canalco® HSG Chamber (#43-001-1) $695
UVT Gel Tray (#43-002-1) $135

Amino acid transport

A Review of Amino Acid Transport Processes in Animal Cells and Tissues. By J. Lerner. Pp. 234. (University of Maine at Orono Press: Orono, Maine, 1978.)

AMINO ACIDS are chemically stable and easy to assay. With rapidly expanding techniques of microperfusion, micropuncture and cell fractionation one might have been forgiven for thinking that most of what was worth knowing about these substances would soon be discovered. This has clearly turned out not to be the case for, despite a torrent of data produced in the past two decades, relatively little is known about the fundamental aspect of transport into and out of cells. The literature is massive, with up to 100 original articles and some half-dozen reviews appearing annually. Professor Lerner is to be congratulated therefore on tackling the mammoth task of reviewing this field and providing a valuable synopsis of current information and concepts.

He accomplishes his task in 177 pages of readable text which cites just over 900 references up to 1976. The index is excellent and the 15 chapters (some of which are a single page in length) are well laid out. Most data described have been derived from marine invertebrates, insects, parasites and mammals (with detailed considerations of transport in the gut, central nervous system and to a lesser extent the kidney), with the intact organism and isolated preparations considered in detail. There is adequate reference to other tissues and isolated cultured cells, with the differing specificity of particular transport systems according to organ and species suitably highlighted.

Perhaps more than anything else, the complex interactions of the amino acids themselves on their own transport and the paucity of synthetic non-competitive specific inhibitors, have hindered the elucidation of mechanistic details. However, of the effects known, those of hormones, mercury, nucleotides, amino acid analogues, vitamins and sugars are suitably described. The important influence of sodium ion concentration is tackled in detail, although rather surprisingly without reference to the elegant work by Ullrich and his collaborators on the isolated rat renal tubule.

Within the context of the whole organism there are interesting observations on the adaptation and regulation of transport and how transport changes during foetal development. Contributions from the clinical front include the inborn errors of metabolism, dietary deficiencies, malabsorption and starvation.

This volume is comprehensive but strictly a review. The theme is usually clear, but on occasions the book would benefit from an overall synthesis and some comment. Sometimes the argument becomes diffuse, points of interest or inconsistency are not highlighted, and there is little speculative comment. It is disappointing (but also indicative of our knowledge) that proposed mechanisms of transport only occupy 10 pages and there is no mention of any possible role for transmembrane peptides which are known to be important in other transport systems. However, despite these observations the work will undoubtedly be of considerable use to research workers in and students of biochemistry, neurochemistry, comparative physiology, nutrition, regulation biology and I think especially clinical science It should find a place in all laboratories working on amino acid metabolism.

C. W. J. Owens is Lecturer in Chemical Science at University College Hospital Medical School, London, UK.

Upper atmosphere, ionosphere and magnetosphere

Handbook of Astronomy, Astrophysics and Geophysics. Vol. 1: The Earth. 1. The Upper Atmosphere, Ionosphere and Magnetosphere. Edited by C. W. Gordon, V. Canuto and W. I. Axford. Pp. 412. (Gordon and Breach: London, 1978.) £35.

As this particular volume represents the first of forthcoming volumes on a very wide range of astronomy, astrophysics and geophysics, a few general comments may be in order on the general editorial matter. First, it is not clear whether or not this particular volume (volume 1) is supposed to cover the entire subjects of "The Upper Atmosphere, Ionosphere and Magnetosphere." If other volumes are planned for the above subjects, it should have been mentioned in an editorial note. How many volumes are planned? Is general subject matter for each volume decided? Or is this going to be a collection of review papers as they come along?

Secondly, the volume consists of six articles, a mixture of comprehensive articles covering a very wide range of topics and those covering rather specific topics. Thus, the general editorial policy for the general planning of this handbook is not very clear. Further, there does not seem to be a uniform format: some have an abstract, some do not. Some articles have one page for the title and some do not. For an extensive article, it would be helpful to have at least a Table of Contents on the cover page. Also, if it is going to be truly a *Handbook* it should have at least a subject index.

Among the articles in the first volume "Hydrogen in the Upper Atmosphere" by B. A. Tinsley, "Auroral Particle Precipitation . . . Observations" by B. A. Whalen and I. B. McDiarmid, and "The Physical Mechanisms of the Inner Van Allen Belt" by M. Walt and T. A. Farley are perhaps the most comprehensive and up-to-date ones in each subject area. The coverage of the article "The Equatorial Electrojet" by D. M. Cunnold is rather limited, and there is little mention of some of the recent developments, such as the relationship between the F region of the ionosphere and the equatorial electrojet. The article "Polar-Cap Absorption Obsevrations and Theory" by G. C. Reid does not cover observations of solar protons in interplanetary space and in the magnetosphere. The coverage of J. R. McAfee's article "Electron Plasma Resonances in the Topside Ionosphere" is reasonable for this limited subject.

Acetylcholine synthesis

Acetylcholine Synthesis in Neurons. By S. Tuček. Pp. 259. (Chapman and Hall: London, 1978.) £15.

In recent years several excellent books on cholinergic mechanisms have been published (for example, *Biology of Cholinergic Function,* edited by A. M. Goldberg, I. Hanin, Raven: New York, 1976; *Neuromuscular Junction Handbook of Experimental Pharmacology,* **42,** edited by E. Zaimis, Springer: Berlin, 1976). As these books have covered many topics of cholinergic transmission in more or less detail, one might wonder whether there is a need for another book on acetylcholine. However, the present monograph aims to be an addition to, rather than a substitute for its forerunners, by giving a detailed analysis of many aspects of transmitter synthesis, a subject which has not yet received the degree of attention it probably deserves. In my opinion the book fulfils its aim in an elegant manner. In the first place it is extremely readable, if only it were for the fact that it measures less than 200 pages of text, in contrast to its more corpulent counterparts, where the busy reader may hesitate reading the full contents at leisure. If one takes into account its compact size the book is admirable in offering so much detail with such clarity. The author never seems to be in a hurry when explaining difficult matters; when there is no way out of a problem, as is often the case with conflicting evidence, he treats the subject with justified economy.

The book sets out with two chapters which nicely summarise what is known about choline acetyltransferase. Among other things the physical and enzymic properties of this protein are discussed, together with its presence in nerves and also in some non-nervous tissues, and its transport in cholinergic axons. Subsequently, there are two very informative chapters devoted to the supply of acetyl and choline moieties which finally form the acetylcholine molecule. The supply of choline and choline-containing substances to the nerves (with special attention to the brain) and the subsequent neuronal uptake of free choline are described, and the problem is discussed how, or rather in what chemical form, activated acetyl groups migrate through the mitochondrial membrane into the cell sap of the nerve terminal. These chapters are followed by a survey of what is known about the organisation and control of acetylcholine synthesis. This actually forms the body of the book, and is also the most interesting part.

In addition to synthesis, the storage and release of acetylcholine are briefly discussed, as there are good reasons to believe that storage and release are intimately connected with the synthetic process. According to the author the synthesis of acetylcholine is probably controlled by mass action, enough choline acetyltransferase being present to provide a rapid recovery from disturbances of equilibrium caused by release of transmitter. High affinity uptake of choline and release of activated acetyl groups by the mitochondrion may represent additional factors in the mechanism controlling acetylcholine synthesis. The turnover of acetylcholine in the living brain receives little attention in this chapter and perhaps some readers will regret this. A full discussion of this subject would have been redundant, because it has been extensively reviewed recently by I. Hanin and E. Costa in a chapter of *Biology of Cholinergic Function,* cited above. The last chapter of the book treats, among other things, the changes of choline acetyltransferase during development and ageing, and during Wallerian degeneration.

The book provides an extensive list of references (papers as recently as 1977 are referenced), which, so far as I have been able to judge, covers practically all that has been published in the field described in the book. It is the kind of reference list which makes the bulk of one's private file of references suitable for the dustbin.

Overall the book is a most valuable source of information on a topic which has not recently been reviewed elsewhere. Further it has the merit of being of educational value for investigators entering into the cholinergic field.

Peter Molenaar

Peter Molenaar is at the Department of Pharmacology, University of Leiden, The Netherlands.

Freshwater fish production

Ecology of Freshwater Fish Production. Edited by S. D. Gerking. Pp. 520. (Blackwell Scientific: Oxford, 1978.) £23.50.

In 1966 a symposium on *The Biological Basis of Freshwater Fish Production* was held at Reading University, England, and the proceedings were published by Blackwells in 1967 as a volume carrying the same title. The book was in great demand and has sadly been out of print for some time. However, the overwhelming response to that volume stimulated the production of the present book. The title has been changed and, although it is still recognisable as a 'reprint' of the earlier edition with many of the same authors simply revising and up-dating their previous articles, it does have some new chapters, some new authors and a somewhat different approach. In addition some of the authors appearing in the first edition are absent from this one. Dr Shelby Gerking has been the editor of both volumes and has done a remarkably fine job. The present *Ecology of Freshwater Fish* is a much better work than its predecessor and, as the former was an excellent text, one can appreciate the high opinion the reviewer has of this present edition.

The book is divided into four main areas: vital statistics of fish populations; the fish population and its food supply; competition and social behaviour influencing production; and the contribution of fish production to human nutrition and well-being. The last section is most welcome, and one worthy of the lengthy treatment it receives this time. It includes contributions on fish yield assessment of large lakes and reservoirs, the growing science of aquaculture, ecological aspects of warmwater fishpond management, and the contribution of freshwater fish to human food, the latter containing a most valuable collection of statistics and up-to-date information.

In the scheme of fish production, information on mortality is required, and one serious omission in this otherwise very complete book is any consideration of mortality from disease, parasitism and predation. Certainly the role of predaceous fish in ecosystems is dealt with in some length, but one would have thought that two papers, one on disease and parasitism, and, one on predation by other animals, would have been a 'must'. There is considerable published work on the effects of disease and predation on both production and yield. Even in the first edition a paper on predation on fish by other animals was included, but for some reason this has been omitted this time.

The book is up to Blackwells usual high quality of production, and only one figure (Fig 127, p320) is sub-standard. It should be in the library of every university department of biological sciences and on the shelves of freshwater fishery staff. It would also be a useful investment for undergraduate as well as postgraduate fisheries students.

Derek Mills

Derek Mills is Senior Lecturer in freshwater ecology and fisheries management at the University of Edinburgh, UK.

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS. AL5 2JQ

PLANT BIOLOGIST *or* PHYSIOLOGIST

with strong biochemical background to study the physiology of vesicular-arbuscular mycorrhizal fungi and the possibility of their culture in artificial media. The post is tenable in the Soil Microbiology Department until January 1982 and is funded by the Ministry of Overseas Development.

Qualifications: First or upper second class Honours degree or the equivalent and at least two years' postgraduate experience. Preference will be given to candidates with appropriate postdoctoral experience in plant or microbial biochemistry and/or root physiology.

Appointment in grade of Higher Scientific Officer (£4,101 to £5.448) or Senior Scientific Officer (£5,154 to £6,898), grade and starting salary depending on experience. At least four years' post qualifying experience would normally be required for appointment as S.S.O. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees and quoting Ref. 374 by January 26, 1979. Further details on request. 8997(A)

UNIVERSITY OF BRISTOL

Applications are invited
for the post of

LECTURER IN ANATOMY

A vacancy exists for a lecturer with a primary responsibility to the teaching of medical students. As well as being responsible for the teaching of gross anatomy to medical, dental, veterinary and science students, the Department offers courses in neuroanatomy, endocrinology, reproduction, embryology, dental anatomy and physical anthropology, with specialised teaching in each of these topics to an Honours degree level.

The Department has excellent facilities for research and is presently organised into a number of research groups working in the following areas: biochemistry and physiology of peptide-secreting neurones, neroanatomy of dopamine pathways, electrophysiology of the CNS, control of parturition, bone mechanics, tooth eruption and physical anthropology.

Salary will be on the scale £3,883 to £7,754 (under review) and letters of application including the names and addresses of **three** referees should be sent to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TD, before February 28, 1979 (quoting ref. TLJ). Interested persons are welcome to visit the Department by arrangement with the Head of Department's secretary (Tel: 0272-24161, Ext. 367). 8895(A)

The British Council

MANAGING EDITOR BRITISH MEDICAL BULLETIN

The British Council, a worldwide educational and cultural organisation, is seeking a Managing Editor for the British Medical Bulletin, which is published three times a year.

The successful candidate will have responsibility for all aspects of the Bulletin's production. This includes presenting subjects to the British Council's Medical Advisory Committee for inclusion in future issues; commissioning and editing contributions (referring when necessary to a specialist scientific editor); and liaising with the printers at all stages.

The Managing Editor also has control over prices, publicity, circulation and sales promotion, and is responsible for the preparation of estimates and settling of fees. In addition he/she will supervise the work of the Bulletin staff, and will represent the Council at meetings of Learned Societies.

Applicants should have editorial or managerial experience in medical/scientific publishing, and a high regard for accuracy in the presentation of printed material. An educational background in the biological sciences would be useful.

Initial salary is around £6,400 including London Weighting, rising by annual increments to £7,497. Annual leave is 22 days. There is an index linked pension scheme which is non-contributory.

For further details and an application form to be returned by January 29, 1979, write or telephone quoting E/4 to: The British Council, 65 Davies Street, London W1Y 2AA, telephone 01-499 8011, extension 3041.

8963(A)

UNIVERSITY COLLEGE LONDON

DEPARTMENT OF PHYSICS AND ASTRONOMY

RESEARCH FELLOW and RESEARCH ASSISTANT

posts are available for work with Professor A. Boksenberg, F.R.S., on observational extragalactic astronomy. The observations will be mainly in the optical range using the Anglo Australian Telescope and other telescopes, but with opportunity for extension into the far ultraviolet using the International Ultraviolet Explorer satellite. The research work includes direct and spectroscopic observations of normal and active galaxies, QSOs and intergalactic matter with related speckle interferometry. The applicants must have proved interpretative ability in at least some of these areas. A background in theoretical astrophysics will be an advantage.

Subject to satisfactory progress the appointment will be to September 30, 1981, with salary according to experience and age within the national salary scale for Research Assistants IA. £3,909 to £6,317, plus £450 London Allowance. The Senior post will carry a salary in the upper part of this range and the Junior post in the lower part.

Applications should be made to Professor A. Boksenberg, F.R.S., Department of Physics and Astronomy, University College London, Gower Street, London WC1E 6BT.

8951(A)

THE UNIVERSITY OF ADELAIDE

invites applications for appointment for three years as a:

RESEARCH FELLOW (A.R.G.C.) X1905 (Biological N.M.R. Spectroscopy)

with Professor L. G. Paleg in the Department of Plant Physiology at the Waite Agricultural Research Institute. The project continues the exploration of aqueous hormone-membrane component interactions and requires a background of training and experience in FT-NMR.

SALARY SCALE: $A15,179 to 681(1) to 680(2) to $A17,220. An economy class airfare and a proportion of removal expenses will be provided. It is expected that there will be provision for superannuation.

APPLICATIONS, **in duplicate**, giving personal, education and professional details, and confidential letters of recommendation pertaining to this position from three referees, should reach the Registrar of the University, G.P.O. Box 498, Adelaide, South Australia, 501 **no later than** January 12, 1979. 8991(A)

UNIVERSITY OF TORONTO SCARBOROUGH COLLEGE

Canada

Chemistry Group invites applications for ASSISTANT PROFESSOR, one-year limited term appointment available July 1 or September 1, 1979. Docorate required with expertise in Physical Chemistry or Chemical Physics. Duties include undergraduate teaching and research. Send curriculum vitae and names of three referees to Chairman, Physical Sciences Division, Scarborough College, West Hill, Ontario, Canada, M1C1A4.

THE INTERNATIONAL CENTRE OF INSECT PHYSIOLOGY AND ECOLOGY

Nairobi, Kenya

Applications are invited from suitably qualified persons for the following positions.

1. RESEARCH SCIENTIST (TERMITE RESEARCH PROGRAMME) REF: SCI/78/27

Qualifications

Ph.D. with 5 or more years of postdoctoral experience in biological or physiological sciences and a demonstrable experience in research on the physiology of insect development. Training and experience in insect sensory physiology and behaviour, and evidence for excellence since doctorate training, will be a distinct advantage.

Responsibilities:

The successful candidate will carry out research on the physiology of caste differentiation among higher termites, with special reference to possible involvement of the endocrine and exocrine systems.

POSTDOCTORAL RESEARCH FELLOW IN PLANT PHYSIOLOGY OR BIOCHEMISTRY (BASES OF PLANT RESISTANCE TO INSECT ATTACK). REF: SCI/78/28.

Qualifications:

Young postdoctoral scientists, newly graduated, whose experience is in plant physiology, plant biochemistry or relevant sciences. High-quality research for Ph.D. and evidence for excellence since doctorate work, will be a distinct advantage.

Preference will be given to gifted young scientists from developing countries.

Responsibilities:

The successful candidate will carry out research in the field of plant physiology and biochemistry vital to plant/insect relationships. Willingness to collaborate with colleagues in other disciplines, especially in insect sciences, will be of paramount importance.

GENERAL INFORMATIONS FOR ALL POSITIONS:

Salary:

Negotiable and include attractive benefits.

Applications giving detailed information on general education, professional qualifications, experience, marital status, age, present terms of employement (including salary) names and addresses of four referees (including one personal), and photostat copies of relevant certificates and diplomas should be addressed to:

Administrative Manager
I.C.I.P.E.
P.O. BOX 30772,
NAIROBI, KENYA.

To reach him not later than 15th January 1979.

8995(A)

NATURE CONSERVANCY COUNCIL

Higher Scientific, Senior Scientific and Principal Scientific Officers

SALARY SCALES

Higher Scientific Officer	£4,101 — £5,448
Senior Scientific Officer	£5,154 — £6,898
Principal Scientific Officer	£6,609 — £8,461

Applications are invited for the following posts in the NCC Field Unit based in Scotland (Edinburgh) and the Chief Scientists Team based in England (Huntingdon).

BACKGROUND

(a) The functions of the FIELD UNIT is to develop a co-ordinated programme of survey and monitoring in SCOTLAND in conjunction with Country HQ, Regions and the Chief Scientist by carrying out appropriate survey and monitoring projects and to synthesise and interpret the results so as to facilitate maximum use of the information by all staff within the organisation.

(b) THE CHIEF SCIENTISTS TEAM provides specialist scientific advice on all aspects of NCCs work and is responsible for the research programme. Members of the team are responsible for ensuring that appropriate research is carried out either by means of contracts placed with research organisations or by the team itself and other NCC staff.

POSTS

1. Field Unit Leader

SCOTLAND (SSO)

A biologist is required, with considerable experience of botanical ecological survey work.

2. Coastal Ecologist

SSO/PSO—CHIEF SCIENTIST TEAM

Substantial knowledge of the flora and vegetation of coastal habitats and experience of associated conservation problems essential.

3. Vertebrate Zoologist

(HSO)—CHIEF SCIENTIST TEAM

Special experience with mammals needed.

AGE AND QUALIFICATIONS

All candidates should have a first or second class honours' degree, or equivalent, in biology, botany, zoology, geology or geography.

Higher Scientific Officer: Candidates should be under 30 years of age, and have at least two years relevant post-graduate experience.

Senior Scientific Officer: Candidates must be at least 25 and under 32 years of age and have at least 4 years relevant post-graduate experience.

Principal Scientific Officer: Candidates should normally be between 30 and 50 years of age.

All posts will ential extensive travelling and possession of a current driving licence is essential.

Application forms and further details are available from Recruitment Section, Nature Conservancy Council, Godwin House, George Street, Huntingdon, Cambs PE18 6BG (Tel: 0480 56191). Closing date for completed application forms is February 2, 1979. Interviews will be held in March 1979.

8952(A)

UNIVERSITY OF SINGAPORE

CHEMICAL ENGINEERING

PROFESSORSHIP

Applications are invited for appointment as Professor in the Department of Chemical Engineering. The successful candidate should have considerable teaching, industrial and administrative experience. Gross monthly emoluments in the range from S$3,745 to S$5,775 approx., the initial amount depending on the candidate's qualifications and experience. In addition, the University pays a 13th month annual allowance of one month's salary in December of each year. Leave, subsidised housing, medical and provident fund benefits are available. Candidates should write to: **The Registrar, University of Singapore, Kent Ridge, Singapore 5,** giving curriculum vitae (bio-data), with full personal particulars and also the names and addresses of three referees.

university of wales

university college of swansea

SENIOR RESEARCH ASSISTANT

HIGH PERFORMANCE SEMI-CONDUCTOR OXIDES

Senior Research Assistant is required for an S.R.C. grant investigating chemical changes in semi-conducting oxides exposed to reducing environments, with the aim of developing gas detectors which will exhibit specificity to certain gases. Instruments which incorporate these detectors will be designed within the **Electrical Engineering Department.**

Applicants should have a good honours degree and preferably research experience in solid state chemistry or an immediately relevant subject.

The appointment is for three years commencing as soon as possible and the remuneration will be up to £4,382 per annum plus U.S.S./U.S.D.P.S. benefits.

Prospective candidates may contact Dr K. J. Gallagher of the Chemistry Department for further particulars and application forms returned as soon as possible.

SENIOR RESEARCH ASSISTANT/RESEARCH ASSISTANT

Applications are invited from engineers/scientists for the post of **Senior Research Assistant/Research Asistant in the Department of Chemical Engineering** to work on a research programme supported by the Natural Environment Research Council. The successful applicant will undertake work associated with the rheological properties of cohesive suspensions occurring naturally in the marine environment.

The appointment, which will be from the soonest date that can be arranged to March 31, 1980, will be on a scale up to £5,367 per annum, together with U.S.S./U.S.D.P.S. benefits.

Closing date for applications, Wednesday, January 31, 1978.

Further particulars and application forms for the above posts (two copies) may be obtained from the Personnel Officer, University College of Swansea, Singleton Park, Swansea SA2 8PP to whom they should be returned by the above date.

8994(A)

UNIVERSITY COLLEGE CARDIFF

DEPARTMENT OF BIOCHEMISTRY

RESEARCH ASSISTANT

Applications are invited for the posotion of RESEARCH ASSISTANT to work with Dr J. Kay on the regulation of a neutral, muscle protease by endogeneous inhibitors. Techniques will involve enzyme and inhibitor purification, affinity chromatography, antibody production, radiolabelling, etc.

The post is available for three years financed by a grant from the Science Research Council. The salary will be in the range: £3,384 to £3,883 (under review). Duties to commence as soon as possible.

Candidates should have a good Honours Degree in biochemistry or a related subject and research experience in protein chemistry/enzymology/radioimmunoassay procedures would be an advantage.

Applications (2 copies), including a curriculum vitae, together with the names and addresses of two referees, should be forwarded to the Vice-Principal (Administration) and Registrar, University College, P.O. Box 78, Cardiff CF1 1XL. Closing date, **January 31, 1979. Please quote reference 1668.**

UNIVERSITY OF LONDON

INSTITUTE OF PSYCHIATRY

RESEARCH ASSISTANT

Applications are invited from recen graduates in pharmacology, bic chemistry or a related discipline, t undertake a behavioural and bic chemical investigation in rodents c the potential use of new drugs for th treatment of Parkinson's disease.

The position, which is supported b the Medical Research Council, i tenable for one year in the firs instance, and may be renewed for u to three years.

Salary £3,214 to £3,684 per annur plus £450 London weighting.

Applicants may visit the Departmen (Department of Neurology) (Professo Marsden and Dr Jenner) by prio arrangement. Phone: 01-703 5411 E 245.

Application forms available from th Secretary, Institute of Psychiatry, D Crespigny Park, Denmark Hill, Londo SE5 8AF. Phone: 01-703 5411 Ex 228, quoting ref: CM/N.

8990(A)

LINCOLN COLLEGE

(University College of Agriculture)

New Zealand

CHAIR OF SOIL SCIENCE

The Council of Lincoln Colleg invites applications for appointment t the above mentioned Chair, resultin from the impending retirement of Pr fessor T. W. Walker. It is th Council's desire to have the appointe take up duties towards the end of 19 or early in 1980.

The Chair in Soil Science is one 15 at the College and the Council anxious to fill the position with a appointee of high standing because the significance of this Chair, not on to the College but also to New Zealan agriculture.

Applicants should hold an advance degree in Science, Agricultural Scien or Soil Science, have had research e perience in some branch of soil scien or soil resources, such as soil fertilit soil chemistry, soil physics, soil biolo and pedology, and have had some e perience in teaching, communicatic or extension.

The successful applicant will appointed as Head of Department ar will be responsible to the Colle Principal for the administration of t Department.

The appointment will be mac within the existing range of professori salaries NZ$23,012 to $29,188 p annum, the commencing salary bei determined by the College Counci Academic salaries are at present und review.

Expenses of appointment reimburs up to specified limits. New Zealar Government Superannuation is ava able.

Further details and general Con tions of Appointment are obtainab from the Secretary General, Associ tion of Commonwealth Universiti (Appts.), 36 Gordon Square, Lond WC1H 0PF, or from the Registrar the College.

Applications close on **February 1 1979.**

Petroleum Engineering

For Major Development of Operations in Iran
c $33,000 to c $37,000 pa nett

OSCO – The Oil Service Company of Iran, (a consortium of 14 international oil companies) is engaged in a major programme of oil and gas production development in South West Iran on behalf of the National Iranian Oil Company. In order to accomplish this task we seek to strengthen our team of senior professionals by making the appointments detailed below.

Initial contracts are for two years. Salaries, according to seniority and experience are paid in US dollars nett of Iranian income tax. Benefits include married or single status accommodation, free medical facilities, life insurance, educational assistance and a bonus on termination of contract.

Project Leader-Reservoir Systems c $37,000 p.a.

Responsible to the Head of Reservoir Systems, you will be leading a small team maintaining and developing reservoir simulation models in order to assist the engineers to determine optimum exploitation strategies. You will control computer time worth approximately $100,000 p.a. using IBM and CDC hardware and programmed in FORTRAN. *(Ref F 581/N)*

Senior Reservoir Engineer c $36,000 p.a.

This is an important specialist appointment requiring advanced knowledge and originality in the application of reservoir analysis techniques, since the Iranian reservoirs present a variety of unusual technical problems. Working largely on your own initiative, you will be responsible for conducting reservoir studies to establish and predict performance and behaviour under various producing conditions. *(Ref F 440/N)*

Senior Petrophysicist-Methods c $33,000 p.a.

You will be responsible for determining from logs and format samples, the physical properties and fluid content of oil reservoirs. You will also play an active part in the training and guidance of well site and office personnel in the petrophysical implications related to their own functions. *(Ref F 259/N)*

Senior Petroleum Engineers - Processing c $33,000 p.a.

Who will be involved in the planning and review of present and future crude oil processing operations within OSCO. This will include forecasting the qualities of stabilized crude and separation gasses under various conditions and the effects of blending crudes from various field or reservoirs. *(Ref F 009/N)*

Candidates for these specialist appointments will need to be graduates in appropriate disciplines – Petroleum Engineering, Chemical Engineering, Physics or Mathematics – aged 30 or over and have had a minimum of eight years' professional experience in the oil and gas industry.

Please write giving full details of your age, education, career history and salary progression to date, quoting appropriate reference number to:
F. R. Wilcockson, Director,
Whites Recruitment Limited,
72 Fleet Street, London EC4Y 1JS.

IRANIAN OIL SERVICES LTD.

8964(A)

Assistant Plant Pathologist

The Agricultural Science Service of ADAS provides farmers and growers with a wide range of vital technical information and advice which is supported by investigation and development work carried out from 12 regional centres across the country. The assistant will join the Plant Pathology Department in Reading, where the work includes advisory, investigational, statutory and promotional activities.

The assistant plant pathologist appointed will primarily be concerned with plant diseases caused by fungi, viruses and bacteria, and also with plant diseases which cannot be attributed to known causes. The successful candidate will supervise the field investigational programme of the department. This will involve frequent field visits to layout experiments, assessing disease incidence using disease assessment keys and writing preliminary reports on the investigation. In addition, the assistant plant pathologist may be expected to supervise the laboratory examination of a wide range of samples and plant materials derived from both advisory and investigational activities and to liaise with farmers in sample collection, promotional activities and surveys.

Candidates, normally aged at least 25 should have GCE passes or Grades A, B or C in English Language and four other subjects, two of which must be in an appropriate scientific subject at 'A' level, *or* HND/HNC in plant pathology or applied biology *or* an equivalent qualification. At least 5 years relevant experience, preferably including practical experience of the plant pathological examination of plant material, and the ability to organise and supervise staff is essential. Candidates must hold a full valid UK driving licence.

Salary, starting at £4,125 rises to £5,205. There are promotion prospects and a non-contributory pension scheme

For further details and an application form (to be returned by 26 January, 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). **Please quote ref: S/5006.**

8945(A)

MAFF:
AGRICULTURAL DEVELOPMENT
ADVISORY SERVICE

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for chemists or chemical physicists for an S.R.C Postdoctoral Senior Research Assistantship for 17 months from as soon as possible to work in collaboration with Dr J. Yarwood on the interaction and dynamics of hydrogen bonded systems in the liquid phase. These studies which include infrared, far-infrared, Raman and neutron scattering studies are also supported by a N.A.T.O research grant and would be carried out at Durham, the Technical University, Braunschweig and at A.E.R.E Harwell. Some experience in one branch of molecular spectroscopy is essential and an interest in the chemical physics of molecular motions and interactions in the liquid phase would be an advantage.

Initial salary £3,883 or £4,133 per annum on National Research Range 1A plus superannuation.

Applications (three copies) naming three academic referees should be sent by January 22, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE

8904(A)

CLARENDON LABORATORY

Oxford

Synchrotron Radiation

Applications are invited for a Postdoctoral appointment to investigate the application of Synchrotron Radiation to X-ray crystallography. The work will involve the design and implementation of two energy-dispersive diffractometers, together with associated computer software, for the new storage ring source under construction at the Daresbury Laboratory. In addition, the appointee will be expected to join in research into other types of X-ray crystallographic experiments at Daresbury and possibly at synchrotron sources elsewhere Applicants should have experience in X-ray diffraction, instrumentation and computing.

The salary scale (under review) will be £3,383 to £6,555, superannuable under U S.S. and the appointment will be for up to 2½ years, depending on age and date of appointment.

Curriculum vitae should be sent to Dr A M. Glazer, Clarendon Laboratory, Parks Road, Oxford OX1 3PU, U.K., to whom references from two referees should be sent directly.

9013(A)

ALFRED HOSPITAL

Melbourne, Australia

ENDOCRINE SCIENTIST

The Ewen Downie Metabolic Unit at The Alfred Hospital, Melbourne, which is affiliated with Monash University, requires a Ph D. Scientist with expertise in Radioimmunoassay, as well as experience with receptor techniques, hormone purification or affinity chromatography. The unit has both clinical laboratory responsibilities with service and research functions. The successful applicant will be able to conduct an active research programme related to either thyroid hormones, the renin-angiotensin system or adrenal steroids

The position involves responsibility for a radioimmunoassay laboratory in addition to the research programme.

Salary dependent on qualifications and experience

For further information send curriculum vitae including bibliography and summary of research interests together with names of three referees to. The Director, Ewen Downie Metabolic Unit, Alfred Hospital.

Official applications should be forwarded to the Director of Personnel Services, Alfred Hospital, Commercial Road, Prahran, 3181, Victoria, Australia.

9018(A)

UNIVERSITY OF OXFORD

E. P. ABRAHAM PROFESORSHIP OF CLINICAL PATHOLOGY

The electors intend to proceed to an election to the E P Abraham Professorship of Chemical Pathology with effect from October 1, 1980. The stipend of the professor is at present £10,828 per annum.

Applications (nine copies), naming three referees but without testimonials, should be received not later than March 26, 1979 by the Registrar, University Offices, Wellington Square, Oxford OX1 2JD, from whom further particulars may be obtained.

8959(A)

INSTITUTE OF Cancer Research (Sutton). A postdoctoral Scientist is required to fill a post that falls vacant on January 1, 1979 in the Radiotherapy Research Department of the Institute of Cancer Research The work of the Department involves the study of the biological effects of radiation and cytotoxic drugs on mouse tumours and on human tumour xenografts, making use of tissue culture techniques to assess in vivo responses Familiarity with mammalian radiobiology, tissue culture, or pharmacology would be an advantage The appointment will be for an initial period of 3 years, with a possibility of extension. Salary in the range £3,883 to £5,129 per annum plus London Allowance of £450 per annum. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref 300/G/136

8966(A)

THE UNIVERSITY OF MANCHESTER

DEPARTMENT OF BIOCHEMISTRY

POSTDOCTORAL RESEARCH ASSISTANT FOR THEORETICAL ANALYSIS OF DNA STRUCTURES

Applications are invited from theoretical chemists or those with related interests to collaborate with Dr B Robson in the theoretical analysis of DNA and smaller analogues using potential function refinement, *ab initio* quantum mechanics and solvent Monte Carlo techniques. A sound knowledge of FORTRAN is required for the adaptation of established computer programmes The appointment is from one to three years at an initial salary of up to £4,382 per annum Superannuation Applications, including curriculum vitae and naming three referees, should be sent to Dr B Robson, Department of Biochemistry, The University, Manchester M13 9PL

9004(A)

UNIVERSITY OF SUSSEX

SCHOOL OF MATHEMATICAL AND PHYSICAL SCIENCES

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a Postdoctoral Research Fellow in the field of Low Temperature Solid State Physics The successful applicant will join a small research team, which is sponsored by the S.R.C and is concerned with experimental studies of many-body effects in metals using quantum oscillations.

The appointment will be for three years, salary on the scale £3,883 to £6,555 per annum (under review), with superannuation benefits

Applications to The Chairman of Physics, School of Mathematical and Physical Sciences, University of Sussex, Falmer, Brighton BN1 9QH, from whom further particulars can be obtained.

9005(A)

Avon Area Health Authority (T)
Southmead Health District

SOUTHMEAD HOSPITAL BRISTOL

Applications are invited for a post of

BASIC GRADE BIOCHEMIST

in the Department of Clinical Chemistry. Preference will be given to candidates having appropriate experience and a postgraduate qualification Opportunities for wide experience are available, but there will be particular emphasis on training in paediatric aspects

Application forms from District Personnel Officer, Southmead Hospital, Bristol BS10 5NE (Tel Bristol (0272) 505050, Ext 162) and should be returned by January 31, 1979

For further information D J. B. Holton (0272) 505050 Ext. 52, or Dr D J Goldie (Ext 51) should be contacted.

ORGANIC CHEMIST–MASS SPECTROSCOPIST

A postdoctoral research fellow

is needed for one year to be in charge of our new mass spectrometer/data (MS 50/Stereo DS50SM/DS50S) system and to supervise our technical assistant.

The work offers interesting structural, analytical and biochemical problems mainly in the natural product field and is conducted in collaboration with several organic research chemists. It involves predominantly application of capillary column GC—high resolution MS in the EI and CI modes as well as ion structural studies.

Applications are invited from candidates with relevant experience in the fields of organic chemistry and mass spectrometry.

The annual salary is about £9,000 and assistance will be given with relocation expenses and in obtaining accommodation.

Please write to Professor C. R. Enzell, Chemical Research Department, Swedish Tobacco Co., Box 17007, S-104 62 Stockholm, Sweden, enclosing a brief *curriculum vitae and references*, before January 31, 1979.

Duties Preparing abstracts in English for the journal *Horticultural Abstracts*, which covers world scientific literature in this field, indexing and answering scientific enquiries.

Qualifications A degree in horticulture, agriculture, botany, or related subject, plus a reading knowledge of at least one European language (German preferred) and the ability to write good English.

Salary: In the scale £2,839 to £5,448, plus a compensatory allowance (taxable but not superannuable) of 3 3 per cent of basic salary to offset personal contribution to superannuation scheme Starting salary according to qualifications and experience Promotion to higher scales on merit

Application forms and full particulars from the Executive Director, Commonwealth Agriculture Bureaux, Farnham House, Farnham Royal, Slough SL2 3BN

Closing date for applications January 29, 1979. 9001(A)

BEHAVIORAL PHYSIOLOGY

The Department of Biology, University of Chicago, invites applications for a faculty position in Behavioral Physiology. For a description of the position and application instructions, write Behavioral Physiologist Search Committee, Department of Biology, University of Chicago, Chicago, Ill 60637 An Equal Opportunity/Affirmative Action Employer. 9024(A)

Biochemist (class 3)

Australian Department of Veterans' Affairs Victorian Branch

Applications are invited from Biochemistry Graduates for the above position, which is the senior non-medical appointment in the Biochemistry Department, Repatriation General Hospital, Heidelberg, Victoria The Hospital, of 550 beds, is a teaching Hospital of the University of Melbourne, and is situated in a pleasant 21 hectares setting in the northern residential suburbs of Melbourne; the Department is modern, spacious and well equipped The successful candidate will be responsible to the Senior Specialist, Biochemistry for all aspects of the Hospital's routine clinical chemistry Support staff comprises 14 Graduate and Technical personnel including two Class 2 Biochemists (Senior Biochemist equivalent), plus Trainees.

Further information may be obtained from Dr J. Green, Senior Specialist, Biochemistry, Repatriation General Hospital, Heidelberg, Victoria, 3081, Australia.

Salary

$A17,116 to $A18,910.

At present rate of exchange, £1 = $A1.71

Qualifications

An appropriate degree or diploma in Science or equivalent qualification Wide experience in clinical chemistry, and a higher qualification in either clinical chemistry or biochemistry desirable

Conditions

Four weeks annual recreation leave Cumulative sick leave Participation in the Australian Government Retirement Benefits Scheme Three months long service leave after 10 years service Fares to Melbourne for the appointee and family and an allowance until permanently housed may be paid

Application

Written applications, giving full details of qualifications and experience and listing 2 or 3 referees should be forwarded to

The Medical Superintendent,
Repatriation General Hospital,
Banksia Street,
HEIDELBERG VIC 3081
AUSTRALIA

Research Fellow in Microbiology

The Pharmaceuticals Division of ICI Ltd wishes to appoint a Research Fellow for a period of two years to study the adhesion of micro-organisms to epithelial surfaces. This work will form part of the Division's overall programme of research in infectious disease embracing viral, bacterial and fungal infections.

Applications are invited from people with research experience in microbial biochemistry, general microbiology or cell biology with a particular interest in the interaction between prokaryotes and eukaryotes.

Our modern research laboratories are situated in pleasant surroundings but within easy reach of main road and rail routes. Conditions of service and salary are excellent for this particular position.

Please write giving details of qualifications and experience to:

ICI

Mr M F Losse Personnel Officer
ICI Ltd
Pharmaceuticals Division
Mereside Research Laboratories
Alderley Park
Macclesfield Cheshire 9008(A)

UNIVERSITY OF OXFORD
DEPARTMENT OF FORESTRY
COMMONWEALTH FORESTRY INSTITUTE
TECHNICIAN Grade IV
£2,955 to £3,402 (under review)

A vacancy exists for a technician to assist with a research project concerned with the wood properties of tropical pines, for which funds are available until March 31, 1980.

A minimum of two 'A' levels (or equivalent) in appropriate subjects is required Duties will include cutting and preparing wood samples, X-ray photography and the use of computers

Applications giving age, qualifications and experience and naming two referees should be sent before January 14, 1979 to — The Administrator, Commonwealth Forestry Institute, South Parks Road, Oxford OX1 3RB 9022(A)

UNIVERSITYOF GLASGOW
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH

Applications are invited for a Postdoctoral Research Assistant to investigate substitution and ^{18}F exchange reactions of uranium (VI) and uranium (V) fluorides in collaboration with Professor D W. A Sharp and Dr J M. Winfield. The post, supported by the S R C, is tenable for three years, and is available from March 1979 Starting salary (1A Scale) in the range £3,883 to £4,382 per annum plus U S.S

Applications, with the names of two referees, should be sent as soon as possible to Dr J M Winfield, Department of Chemistry, University of Glasgow, Glasgow G12 8QQ, from whom further particulars may be obtained.

In reply please quote Ref. No 4344M. 9002(A)

SIR WILLIAM DUNN SCHOOL OF PATHOLOGY
RESEARCH ASSISTANT
(Grade 1A— Salary £3,383 to £6,555)

Applications are invited for a Research Assistant, supported by the Cancer Research Campaign, to assist with research into the biochemical mechanisms of virus growth. Experience with mammalian tissue culture would be an advantage. Applicants should possess a degree or equivalent qualification.

Applications, in writing, together with the names and addresses of two referees, to the Administrator, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE. 8960(A)

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF CANCER STUDIES

A postdoctoral Research Fellow is required to join a team of scientists studying the proteins of normal and transformed cells The project will be of three years duration and the successful candidate will be expected to have a good biochemistry background and a working knowledge of protein separation techniques Salary will be in the range £3,883 to £6,555

Applications, giving a full curriculum vitae, a copy of the synopsis of their Ph.D , thesis and the names of two academic referees, should be sent to Professor D. G Harnden, Department of Cancer Studies, Medical School, University of Birmingham B15 2TJ 8988(A)

UMIST
LECTURER IN INORGANIC CHEMISTRY

Applications are invited from candidates of either sex for a post of Lecturer in Inorganic Chemistry. The Department of Chemistry has a full teaching programme in Inorganic Chemistry for Honours and Ordinary degrees of the University of Manchester, and has excellent analytical, spectroscopic and synthesis services for research.

Salary will be according to age and experience on the scale £3,883 to £7,754 The appointment will begin as soon as possible.

Application forms and further particulares can be obtained from the Registrar, U M I S T., P.O Box 88, Manchester M60 1QD, or from the Head of Department, Professor P. G Ashmore, and should be returned by February 28, 1979 at the latest.

ROTHAMSTED EXPERIMENTAL STATION
HARPENDEN, HERTS AL5 2JQ
SCIENTIFIC OFFICER

required for Field Experiments ction Duties include participation the work of the Section, such as eparation and editing publicity aterial describing the general agri- ltural work of the Station, con- cting tours of the Station and monstrations of field experiments r scientists, farmers and members the general public

Qualifications Degree in Agricul- re or other related science, or uivalent qualification plus familiarity th agriculture Driving licence ential.

Appointment is grade of Scientific ficer (£2,839 to £4,415) with starting lary according to qualifications and perience Non-contributory super- nuation

Apply in writing to the Secretary, ving names and addresses of two ferees, and quoting Ref 383 by nuary 31, 1979. Further details on quest 9021(A)

UNIVERSITY COLLEGE LONDON
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANT

To work with Professor P H arke on the isolation of the amidase gulator protein of Pseudomonas ruginosa and to carry out in vitro dies on amidase synthesis

The post is financed for three years the Science Research Council

Applications giving details of quali- ations and the names of two erees should be sent as soon as ssible to Professor P H Clarke, partment of Biochemistry, Univer- y College London, Gower Street, ndon WC1E 6BT 8949(A)

UNIVERSITY OF BRISTOL
EPARTMENT OF PATHOLOGY
POSTDOCTORAL RESEARCH ASSISTANT

Applications are invited from bio- ical scientists with interests in ology, cell biology or immunology. e successful applicant will join a m investigating lymphocyte-virus eractions during EB virus infection vitro The appointment will be for e year in the first instance with e possibility of annual renewal plies, in writing, giving the names l addresses of two referees to Pro- sor M A Epstein, Department of thology, The Medical School, Uni- sity Walk, Bristol BS8 1TD by uary 26, 1979. 8993(A)

OVERSEAS DEVELOPMENT
KNOW-HOW: vital to developing countries

Seed Technologist Malawi

Suitably experienced specialist in seed production techniques and seed certification is required to undertake an assignment as Head of the Seed Technology Unit of the Ministry of Agriculture and Natural Resources The Unit is responsible for the quality control of all certified seed produced in Malawi, and is expected to work in close association with the newly formed National Seed Company Based at Chitedze Research Station, outside the capital Lilongwe, the Unit incorporates a laboratory fully equipped to international standards and is a member of the International Seed Testing Association. The Unit currently has a staff complement of ten. Staff training, the seed Inspectorate in particular, will be an important function of the assignment. The post requires good training capability, experience of research and of developing countries also desirable Background knowledge of tropical cereals and pastures and tobacco an advantage

Appointment 2½ years. Salary (UK taxable) in range £6,300-£9,700 pa, plus tax free overseas allowance in range £1,225-£2,635 pa (Ref 331X).

The post is wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating post concerned, and giving details of age, qualifications and experience to:—

ODM
HELPING NATIONS HELP THEMSELVES

UMIST
RESEARCH ASSISTANT IN CHEMICAL PHYSICS

A Research Assistant, preferably postdoctoral, is required to help with calculations in molecular quantum mechanics, including studies of unusual configurations of small molecules and of a new method of electron population analysis Previous, experience in quantum chemistry and computation would be an advantage Salary in the Scales for Research and Analogous Staffs up to £4,382 according to age and experience The appointment would be for two years, with possible extension for a third year

Enquiries and applications to Professor D W J. Cruickshank, Chemistry Department, U.M.I.S.T., Manchester M60 1QD by January 31, 1979 at latest. 8740(A)

ANALYST TECHNICIAN
(Grade 6)

required for Department of Geology, University of Reading Preference given to applicants experienced in wet chemical methods for silicate analysis, but those with substantial experience in general inorganic analysis by atomic absorption and Auto Analyser techniques also considered Salary according to qualifications and experience in range £3,654 to £4,365 per annum (under review) Further details under Ref. T.N 79A from Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading RG6 2AH, to whom applications should be sent to arrive not later than January 26, 1979. 8941(A)

MEDICAL RESEARCH COUNCIL
UNIT ON THE EXPERIMENTAL PATHOLOGY OF SKIN
BIOCHEMIST

required to work on the protein and glycoprotein components of the plasma membranes of normal and pathological epidermal cells.

Applicants should have a Ph.D and a practical knowledge of cell fractionation techniques and membrane biochemistry is essential

Medical Research Council conditions of service. Salary according to age and qualifications

Applications, with the names of two referees, should be sent to the Director, M.R.C Unit on Experimental Pathology of Skin, The Medical School, Birmingham B15 2TJ.

8985(A)

POSTDOCTORATE OR RESEARCH ASSOCIATE IN FISH ECOLOGY

Applications are solicited from individuals with expertise in fish ecology or closely related fields Marine and/or larval fish experience desirable but not essential Successful applicant will coordinate study of interspecific interactions among larval fishes in the St Lawrence estuary. Tenure up to three years Forward curriculum vitae and two letters of reference by February 15, 1979 to:

Dr W C. Leggett, Biology Department, McGill University, 1205 McGregor Avenue, Montreal, P.Q. H3A 1B1. 9009(A)

WELSH NATIONAL SCHOOL OF MEDICINE
(University of Wales)
DEPARTMENT OF HAEMATOLOGY
RESEARCH OFFICER

A graduate in biochemistry or a related discipline is to be appointed for an initial period of three years to develop techniques of culturing differentiating human erythroid cells using suspension and colony culture techniques The main aim of this work will be to establish factors influencing proliferation, iron metabolism and haem synthesis in normal subjects and patients with haematological disorders

Salary within the range £3,384 to £6,555 (under review) for University Research and Analogous Staff, starting point dependent upon age and qualifications

Applications, which should take the form of a brief curriculum vitae with the names and addresses of two referees, should be sent to the Registrar and Secretary, Welsh National School of Medicine, Heath Park, Cardiff CF4 4XN (quoting ref No H24/1) by January 22, 1979. The Department may be visited by appointment with Professor A. Jacobs (tel. No 0222/755944, ext. 2375). 9016(A)

Department of Health and Social Security

Pharmacists/ Chemists

The British Pharmacopoeia Commission is responsible for all standards published in Britain for substances and articles used in human and veterinary medicine. The pharmaceutical tests and methods of analysis included in their publications, have largely been evolved in the Pharmacopoeia Laboratory, which is equipped for a range of spectroscopy, chromatography, classical analysis and physical testing.

As a member of a team of scientists, located in Canons Park, Middlesex, the pharmacists/chemists appointed will critically examine proposed specifications for medical substances, and prepare reports for submission to the appropriate committee; maintain quality control measures for medical chemical reference substances used in assays and tests of the British Pharmacopoeia and assist in the development of suitable analytical methods for routine control of pharmaceuticals.

Candidates, normally aged under 27, should already have a good honours degree in chemistry or pharmacy or closely related discipline. Relevant experience is highly desirable, although the job would suit a recently qualified scientist with some experience of laboratory techniques.

Appointment as Scientific Officer (£3110-£4690) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 26 January 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). *Please quote ref: SB/13/KD.*

FACULTY POSITION IN EXPERIMENTAL ASTROPHYSICS

The Department of Physics and Astronomy at Northwestern University invites applications for an Assistant Professorship available for September, 1979. This is tenure-track position with an initial appointment for three years. We are seeking a candidate with research experience in observational/experimental astrophysics, and a strong commitment for teaching both astronomy and physics courses. Applications should include a full résumé and the names of at least three references whom can be contacted for letters of recommendation. Please send all applications to: Astrophysics Search Committee, Department of Physics and Astronomy, Northwestern University, Evanston, IL 60201. The closing date for applications will be **March 1, 1979.** Northwestern University is an equal-opportunity/affirmative action employer and welcomes applications from women and members of minority groups.

8978(A)

ASSISTANT PROFESSOR OF ANALYTICAL CHEMISTRY

—tenure track, fall 1979. Send curriculum vitae with a 250-word outline of your research interests. and request 3 letters of recommendation, to Dr D. H. Freeman (Chairman, Search Committee), Department of Chemistry, University of Maryland, College Park, MD 20742 U.S.A. E.O./A.A.E.

8968(A)

THE UNIVERSITY OF MANCHESTER

FACULTY OF MEDICINE

VETERINARY OFFICER

A veterinary graduate with experience in the care and use of laboratory animals is required to manage experimental animal facilities for the Faculty. These will comprise the animal floor of the New Medical School building, extending to about 36,300 sq. feet and an outstation for larger animals and for certain breeding operations. In addition there are separate University-supervised animal facilities at the University Hospital of South Manchester and Hope Hospital, Salford, for which the veterinary officer will be responsible. These facilities cater for all the requirements in the Faculty, including clinical departments. The appointee will be encouraged to pursue his or her own research.

Salary range per annum: £7,508 to £9,263. Superannuation.

Particulars and application forms (returnable by January 15) from the Registrar, The University, Manchester M13 9PL. Quote reference 276/78/N.

8881(A)

NATURAL ENVIRONMENT RESEARCH COUNCIL

DIRECTOR

Institute of Geological Sciences

Applications are invited for the post of Director of the Institute of Geological Sciences, which will become vacant in May 1979 on the retirement of the present Director. The Institute is a constituent body of the Natural Environment Research Council.

It is the primary geological research and advisory body in the United Kingdom, its research covering the earth sciences, including palaeontology, petrography, geophysics, hydrogeology and geochemistry. A considerable proportion of the Institute's work (over 80% currently) is funded by commissions from Government Departments, the EEC and other organisations; work is also carried out for overseas governments and as technical assistance through the Ministry of Overseas Development.

The Institute is in the process of moving many of its functions and staff to a site at Keyworth near Nottingham, where about 650 staff will eventually be based. One of the main concerns for the new Director will be to bring this operation to completion over the next few years and he will establish the Directorate at Keyworth at a suitable time.

The post calls for a geologist of international reputation with a successful record of administration of research and the ability to provide leadership to this large research organisation, which at present has over 1,100 staff.

The post is graded at Under Secretary with a salary from April 1 1979 of £14,714 rising to £16,000 on April 1, 1980. There is a non-contributory superannuation scheme.

Application forms are available from Mr. F. S. Rosier, Natural Environment Research Council, Establishments Division, Polaris House, North Star Avenue, Swindon SN2 1EU (telephone 0793-40101) and should be returned by February 9, 1979.

9035(A)

UNIVERSITY OF GLASGOW MECHAN CHAIR OF AERONAUTICS AND FLUID MECHANICS

Applications are invited for the Mechan Chair of Aeronautics and Fluid Mechanics.

Candidates should have had experience in research, development or design concerned with aircraft or missiles, or their related propulsion, control or navigation systems.

Further particulars may be obtained from the Secretary of the University Court (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (15 copies, or in the case of overseas applicants, one copy), together with the names and addresses of three referees, should be lodged on or before February 15, 1979.

In reply please quote Ref. No. 4336M.

8943(A)

UNIVERSITY OF GLASGOW JAMES WATT CHAIR OF MECHANICAL ENGINEERING

Applications are invited for the James Watt Chair of Mechanical Engineering.

Candidates should have had experience in research, development or design concerned with Engineering Thermodynamics and Heat Transfer and its relation to Fluid Mechanics. This experience could have been in the mechanical, chemical or process engineering fields.

Further particulars may be obtained from the Secretary of the University Court (Room 18), University of Glasgow, Glasgow G12 8QQ, with whom applications (15 copies, or in the case of overseas applicants, one copy), together with the names and addresses of three referees, should be lodged on or before February 28, 1979.

In reply please quote Ref. No. 4337M.

8944(A)

AARHUS UNIVERSITY (DENMARK)

A position as lektor (associate professor with tenure or assistant professor according to qualifications) will be vacant at the Department of Molecular Biology, Aarhus University, Denmark, from June 1, 1979.

A molecular biologist is wanted for the position to work in the field of regulation of expression of essential genes in *E. coli.*

Present permanent staff in the group are Kirsten Gausing, Poul Jørgensen and Niels Ole Kjeldgaard.

The successful applicant must on equal terms with the other members of the group, share the teaching responsibilities — from first-year level to supervision o graduate and postgraduate students It is expected that the successfu applicant eventually will be able to teach in Danish.

Applications containing curriculum vitae, information on scientific and educational activities, a list of publications plus wherever possible 3 copies of published material, and any additional information relevant for the evaluation of the applicant's scientific and educational qualifications should be sent to the Faculty of Science, Aarhus University, Ndr Ringgade 1, DK-8000 Arhus C Denmark before February 15, 1979 The report of the evaluation committee will be sent to all applicants

Further information as regard salary etc. can be obtained from the Department of Molecular Biology, Aarhus University, Universitetsparken, DK-8000 Arhus C Denmark.

8992(A)

UNIVERSITY OF BRISTOL

Applications are invited
for the post of

RESEARCH ASSISTANT/ ASSOCIATE

Within the Department of Anatomy. The post is tenable for up to three years and the appointee will join Professor B T. Pickering's group studying the biosynthesis, ultraneuronal transport and release of neurohypophysical polypeptides. Applicants should have some experience of biochemical, pharmacological, ultrastructural or immunocytochemical techniques; and be in possession of either a Ph.D. or a medical qualification.

Salary will be on the scale £3,883 to £6,555 (under review). Letters of application including curriculum vitae and the names of three referees should be sent to the Registrar and Secretary, University of Bristol, Senate House, Bristol BS8 1TH before January 31, 1979 (quoting ref TLJ) 8896(A)

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(University of London)

Denmark Hill,
London SE5 8RX

POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post, which will be supported by a grant from the Cancer Research Campaign to Dr Norman.

The project will involve the use of human lymphoid cell line for the in vitro* investigation of interactions between steroids and other drugs used in the treatment of leukaemia

The appointment will be for three years, with a starting salary of £4,882 per annum plus £450 London Weighting Further particulars may be obtained from the Secretary of the Medical School to whom applications, including full curriculum vitae and naming two referees, should be sent by January 31, 1979. 8989(A)

TECHNICIAN (Grade 4) required in Department of Agriculture and Horticulture, University of Reading, to work on projects, supported by the International Board for Plant Genetic Resources, concerned with the long-term storage of seeds for genetic conservation, under the direction of Professor E. H. Roberts The work involves preparing seeds for low-temperature storage, monitoring deterioration under storage using germination tests and various other physiological techniques H N.C or equivalent qualification desirable. One year appointment in first instance with possibility of renewal. Salary in scale £2,955 to £3,402 per annum (under review). Apply with full details of qualifications and experience, names of 2 referees, and earliest date of starting, quoting Ref TN03A, to Assistant Bursar (Personnel), University of Reading, Whiteknights, Reading, Berks. RG6 2AH. 9017(A)

UNIVERSITY OF LONDON KING'S COLLEGE

RESEARCH TECHNICIANS GRADE 5

Two research technicians required in Department of Physics. One to work with Solid State Physics Group. Main responsibilities will be the maintenance, development and setting up of research equipment and preparation of samples. Preference will be given to applicants with experience in either electronics or high vacuum and cryogenic techniques.

The second technician required to work mainly for Infra-Red Spectroscopy and High-Pressure Group. Preference will be given to applicants with experience in spectroscopy or crystal growing and preparation techniques.

The salary for both posts is on scale £3,651 per annum (inclusive) (under review) rising to £4,185. Four weeks holiday annually Contributory pension scheme Apply in writing with full details to The Head Clerk (Ref N210203) King's College London, Strand WC2R 2LS. 9039(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

(University of London)

SCHOOL OF PATHOLOGY

RESEARCH IN CHEMICAL CARCINOGENESIS

Applications are invited from recent graduates for the post of Research Assistant to work on the mechanism of malignant transformation of brain cells by nitrosamides Cell culture techniques are used extensively in this project. A background in Microbiology, Biochemistry or Molecular Biology would be advantageous The post, funded by the Cancer Research Campaign, is available immediately, and potentially tenable up to December 31, 1981 Starting salary £3,858 per annum including London Allowance

Applications including a curriculum vitae and the names of two referees to, Dr J P. Roscoe, (N) The Middlesex Hospital Medical School, School of Pathology, Riding House Street, London W1P 7LD 9033(A)

THE MIDDLESEX HOSPITAL MEDICAL SCHOOL

SUB-DEPARTMENT OF MOLECULAR BIOPHYSICS

RESEARCH ASSISTANT

Applications are invited for the above post, financed by the World Health Organisation, to work on peptide secretion from human tumour cells Experience of tissue culture techniques and/or radioimmunoassay desirable but not essential

Salary within the range £3,858 to £5,340 per annum (including London Allowance) according to age and experience.

Applications, including a curriculum vitae and the names of two referees should be sent to The Secretary, (N) Sub-Department of Molecular Biophysics, Department of Nuclear Medicine, The Middlesex Hospital Medical School, London W1N 8AA by January 26, 1979. 9032(A)

AGRICULTURAL RESEARCH COUNCIL FOOD RESEARCH INSTITUTE

Applications are invited for the following posts which have arisen from the recent formation of a Nutrition and Food Quality Division.

(1) PHYSIOLOGIST

Nutrient Interactions Group
(Senior Scientific Officer/Principal Scientific Officer Grade)

First or Upper Second Class Honours degree in Physiology with at least four years' relevant postgraduate experience, including studies on intestinal absorption, and preferably a Ph D. Quote ref: 77/3.

(2) NUTRITIONIST

Nutrient Interactions Group
(Higher Scientific Officer/Senior Scientific Officer Grade)

First or Upper Second Class Honours degree in Nutrition or Physiology/Nutrition with at least 2 years' post-graduate experience, including nutritional studies with small animals. Quote ref: 75/8.

(3) ASSISTANT NUTRITIONIST

Nutrient Interactions Group
(Scientific Officer Grade)

Degree or HNC, HND or equivalent qualification in nutrition or related subject. Quote ref: 77/2

(4) NUTRITIONIST

Nutritional Composition Group.
(Higher Scientific Officer/Senior Scientific Officer Grade)

First or Upper Second Class Honours degree in Nutrition or closely related subject with at least 2 years' post-graduate experience in connection with the analysis of foods or assessment of their nutritional value. Quote ref. 77/8.

(5) SENIOR LABORATORY ANIMAL TECHNICIAN

(Scientific Officer Grade)

Associateship of the Institute of Animal Technicians or equivalent qualification and several years' post-qualifying experience required. Quote ref: 75/12.

Salary Scales:

Principal Scientific Officer ..	**£6,609 — £8,461**
Senior Scientific Officer .	**£5,164 — £6,898**
Higher Scientific Officer .	**£4,101 — £5,448**
Scientific Officer	**£2,839 — £4,415**

Non-contributory superannuation scheme at age 18 years and over. Five day week and flexible working hours scheme operated

Application form and further particulars from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA. Closing Date: 19th January, 1979. 8948(A)

NEW ZEALAND UNIVERSITY OF CANTERBURY

Christchurch

Applications are invited for the following positions

SENIOR LECTURER/ LECTURER IN COMPUTER SCIENCE

Applicants should have interests within the (very broad) areas of computer systems and languages, theory of computing, information systems, or other areas of non-numerical applications. Preference may be given to an applicant qualified in data base techniques, information systems and related areas.

The salary for Lecturers is on a scale from NZ$11,894 to NZ$14,488 per annum. Promotion may be made on academic merit to Senior Lecturer where the salary range is from NZ$14,983 to NZ$17,145 (bar), NZ$18,380 per annum.

Applications close on *February 28, 1979.*

Particulars, including information on travel and removal allowances, study leave, housing and superannuation, may be obtained from the Association of Commonwealth Universities (Appts), 36, Gordon Square, London WC1H 0PF. 9043(K)

THE UNIVERSITY OF LEEDS

DEPARTMENT OF EARTH SCIENCES

Applications are invited for a post of

POSTDOCTORAL RESEARCH FELLOW

for work on palaeomagnetic studies of metamorphic cooling in the Scottish Caledonides on a project financed by the Natural Environment Research Council. The appointment will be made for a fixed term of three years and the successful candidate will work under the direction of Professor J. C. Briden. It is hoped to make an appointment with effect from April 1, 1978 or as soon as possible thereafter.

Salary in the range £3,883 to £4,382 on the IA scale Research and Analogous Staff (£3,883 to £6,555) (under review).

Application forms and further particulars may be obtained from the Registrar, The University, Leeds LS2 9JT, quoting reference number 49/10D Closing date for applications February 19, 1979. 9027(A)

The International Atomic Energy Agency

seeks for its laboratory at Monaco a Senior Marine Alpha Radioactivity Specialist. An advanced University degree in chemistry, physics or chemical oceanography and 10 years' experience in polonium and plutonium techniques are essential. Initial contract two years. Emoluments depending on experience US$35,000 per annum tax-free. Additional allowances if married. Travel and removal expenses paid. Six weeks annual leave. Send curriculum vitae under VN 61/78 to IAEA, Division of Personnel, P.O. Box 590, A-1011 Vienna, Austria. 8976(A)

UNIVERSITY OF SURINAME

Faculty of Natural Resources
Department of Geology and Mining

TEACHING POSTS IN GEOLOGY AND MINING

GENERAL: The Department is a part of the recently established Faculty of Natural Resources. The course now offered is of B.Sc. level. It is, however, likely that in the near future graduate student will be admitted.

The period of first contract for non-Surinamese staff members is three years, whereupon the contract may be extended. Annual salary is the equivalent of US $11,000 (under review), the contract bonus 25% thereof. On first appointment and on termination the University will pay the air passage and a baggage allowance.

Applicants for these posts should hold the degree of M.Sc. or equivalent with considerable teaching and research experience preferably in the tropics. Possession of a Ph.D. is an advantage, just as management experience.

DUTIES WILL INCLUDE:

—teaching (a wide range) of geology and mining subjects;

—to evaluate, adjust and develop the programme of study;

—participation in the research programme of the faculty;

—to carry out organisational activities.

For information please write to the Board of the Faculty of Natural Resources, P.O.B. 1914, Paramaribo, Suriname (S.Am.). 8998(A)

LOTHIAN HEALTH BOARD
PRINCIPAL GRADE CYTOGENETICIST

Applications are invited for the above post based at the Department of Pathology, Royal Hospital for Sick Children, Edinburgh.

Candidates must be graduates with considerable experience in all aspects of cytogenetic theory and practice. A higher degree would be considered essential The successful applicant would be expected to partake in medical undergraduate teaching. The Department is responsible for practical cytogenetic diagnosis on a supra-area basis. Consideration would be given to offering the successful candidate honorary University status.

Arrangements to visit the unit may be made by telephoning 031-667 1991, ext 270.

Applications which should be typewritten, giving particulars of age, qualifications and previous experience, together with the names and addresses of two referees should be lodged with the Secretary, 11 Drumsheugh Gardens, Edinburgh EH3 7QQ within two weeks from the date of this advertisement.

9025(A)

COUNTY OF SOUTH GLAMORGAN

INSTITUTE OF HIGHER EDUCATION

Faculty of Science

DEPARTMENT OF SCIENCE

Applications are invited for the following full-time appointment commencing in February 1979. The appointment will be in a temporary capacity because of the absence on maternity leave of the present holder of the post The approximate date of termination will be in July, 1979.

SENIOR LECTURER IN NUTRITION and PHYSIOLOGY

Salary: £6,051 to £7,572

Applicants should be graduates with appropriate teaching experience The person appointed will be involved in the teaching of Nutrition to diploma and undergraduate dietetics students and to students studying the Food Science Option of an H N D Course in Applied Biology Physiology will be taught to students attending Dietetics and Nursing Diploma Courses.

Application forms and further particulars are obtainable from the Deputy Principal, South Glamorgan Institute of Higher Education, Llandaff Centre, Western Avenue, Cardiff CF5 2YB, to whom they should be returned within 10 DAYS of the appearance of this advertisement.

F. J. Adamas, Director of Education, Education Offices, Kingsway, Cardiff. 8946(A)

BEDFORD COLLEGE
(University of London)
SAFETY/RADIATION PROTECTION OFFICER

Applications are invited for the above new post for an officer with a scientific/technical bias to work under the direction of the College Secretary in ensuring compliance with statutory requirements particularly with regard to radiological protection Previous practical experience of radioisotope and/or radiation work essential Initial salary within gross range £3,834 to £7,005 p a Further particulars from the undersigned to whom applications must be submitted by February 22, 1979

Senior Assistant Secretary N (Personnel), Bedford College, Regent's Park, London NW1 4NS, Tel 01-486 4400, Ext 312 9037(A)

THE UNIVERSITY OF WEST INDIES—TRINIDAD

Applications are invited for the vacant temporary post of:

SENIOR LECTURER/ LECTURER/ASSISTANT LECTURER

in the

DEPARTMENT OF LIVESTOCK SCIENCE, FACULTY OF AGRICULTURE

Preference will be given to applicants holding a first degree in animal science or veterinary medicine with postgraduate qualifications in animal physiology Interest and experience in the physiology of dairy cattle reproduction (infertility) and/or adaptation of ruminants to hot, humid climates would be an advantage The appointment will be for 2 years with the possibility of extension for a total of 5 years

Salary Scales (1977-78 under review) Senior Lecturer, TT$25,827 to 34,017 per annum, Lecturer TT$19,071 to 29,799 per annum; Assistant Lecturer TT$15,480 to 16,974 per annum (£1 sterling=TT$4 74) F S S U Unfurnished accommodation if available at 10% or furnished at 12½% or housing allowance of 20% of pensionable salary Family passages. Study and Travel Grant

Detailed application (2 copies) with curriculum vitae and naming three referees to be sent direct to Secretary, U W I, St Augustine, Trinidad, as soon as possible Applicants resident in the U K should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT Further details may be obtained from either address. 8956(A)

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appoin ment to the following.

Research School of Earth Sciences

ENVIRONMENTAL GEOCHEMISTRY

RESEARCH FELLOWS
(2 posts)

The School is proposing to con mence work in Environmental Ge chemistry and invites application from appropriately qualified eart scientists This is an interdisciplina field embracing atmospheric chemistr chemical oceanography and palae climatology, and involves the study the chemical interactions between t atmosphere, hydrosphere and sol earth

Initially the appointees will attached to the isotope group head by Dr W Compston, where ma spectrometric facilities for stable a radiogenic isotope geochemistry a available While specific research topi have not yet been chosen, it is expe ted that studies will be orient towards the carbon cycle and palae climatology in the southern hemisphe using C, O isotopic analyses.

Exceptionally well qualified cand dates may be considered for appoin ment at Senior Research Fellow lev

CLOSING DATE. **MARCH 3 1979.**

Salary on appointment will be accordance with qualifications and e perience within the ranges Seni Research Fellow $A21,201 to $25,2 per annum, Research Fellow $A15,1 to $19,813 per annum Current e change rates $A1=$US1 14 · £0 58

Tenure: Appointment as Seni Research Fellow/Research Fellow normally for 3 years in the fi instance with the possibility of ext sion to 5 years

Reasonable appointment expenses a paid Superannuation benefits a available for applicants who a eligible to contribute Assistance w housing is provided for an appoint from outside Canberra

The University reserves the ri not to make an appointment or make an appointment by invitation any time.

Prospective applicants should obt further particulars from the Asso tion of Commonwealth Universit (Appts.), 36 Gordon Square, Lond WC1H 0PF. 8955(A)

UNIVERSITY OF CAMBRIDGE
UNIVERSITY LECTURER or ASSISTANT LECTURER
in CHEMICAL ENGINEERING

Applications are invited for the post of University Lecturer or Assistant Lecturer in Chemical Engineering. The successful applicant will take part in the teaching programme in the Department, and is also expected to undertake research in a field of his or her own choice. Graduates in chemical engineering would be particularly appropriate candidates, but applications will also be welcomed from graduates in other branches of engineering, or in chemistry, biochemistry or physics. Industrial experience would be an advantage but is not essential.

For a Lecturer, the initial appointment is for three years with the possibility of re-appointment to the retiring age. The present pensionable scale of stipends for a University Lecturer is £5,367 a year, rising by 12 annual increments to **£8,257.**

For an Assistant Lecturer the initial appointment is for three years with the possibility of re-appointment for two further years. The present pensionable scale of stipends for a University Assistant Lecturer is £4,133 a year, rising by four annual increments to £5,129 a year.

Further information may be obtained from Professor J. F. Davidson, Department of Chemical Engineering, Pembroke Street, Cambridge CB2 3RA. Closing date February 28, 1979. 9026(A)

ANIMAL HEALTH TRUST
SMALL ANIMALS CENTRE
SENIOR
RESEARCH ASSISTANT

We are expanding our renal research
ıit and wish to appoint a senior re-
arch assistant with suitable experi-
ıce in applied Biochemistry to assist
the investigation of canine chronic
nal disease. The successful candidate
ill be expected to take an active
terest in the project as a whole and
apply a variety of separation tech-
ques to the study of urine proteins
d "uraemic toxins". This five year
llaborative study is supported by the
ellcome Trust. The initial appoint-
ent will be for a three year period.
arting salary will be in the range
,032 to £5,697 (with F.S.S.U./U.S.S.)
cording to age and experience.

Technical staff with suitable experi-
ıce are invited to apply.

The laboratories are modern, well
uipped and situated four miles from
ewmarket, in pleasant park land.

For further information please con-
ct Dr D. F. Macdougall at The Ani-
al Health Trust, Small Animals
entre, Lanwades Park. Kennett, Nr.
ewmarket, Suffolk, CB8 7PN. (Tel:
38—750543).

Applications, to include full curri-
ılum vitae and the names of two
ferees, to the Director, by February
1979. 9030(A)

ASSISTANT PROFESSOR

The Division of Tumor Immunology
seeking a new faculty member at
e assisting professor level. We are
eking an investigator with a strong
terest and previous experience in
ıalysing and characterising the hu-
an cellular immune response. Wo-
en and minority candidates are
ıcouraged to apply. Please send cur-
culum vitae and the names of three
ferences to: Search Committee, Divi-
on of Tumor Immunology, Sidney
ırber Cancer Institute, 44 Binney
reet, Boston, MA 02115. An Equal
pportunity/Affirmative Action Em-
oyer. 9029(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY
JUNIOR BIOCHEMIST

Applications are invited for the post
Junior Biochemist at EMBL's
ıtstation at **Grenoble, France.**

The successful applicant will join a
search project on aspects of muscle
ochemistry, in particular the deter-
ination of the amino-acid sequence
the rod portion of the myosin
olecule. Information on this
quence will be used as primary data
r physical structural studies involv-
g such techniques as electron
icroscopy, X-ray and neutron
ffraction.

A Ph.D. qualification, followed by
me experience in an appropriate
ld, is required.

The salary offered will be **FF 6643**
onthly, after deduction of tax.
rtain allowances are payable in
dition, depending on personal
rcumstances.

Applications, quoting **reference 79/1,**
th curriculum vitae and a brief
atement of interests, together with
mes of referees, to:—

Sir John Kendrew, Director General,
MBL, Postfach 10.2209, D-6900
idelberg, Germany. 9040(A)

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
TECHNICIAN 4

Required in Biochemistry Department to work on a 2 year C.R.C. project involving virus-cell interactions. Duties will include preparing specimens for electron microscopy and photography. Appropriate laboratory experience essential. HNC or degree desirable. Application forms available from the Establishment Officer, St George's Hospital Medical School, Cranmer Terrace, London, SW17 0RE. 9028(A)

UNIVERSITY OF LONDON
KING'S COLLEGE
RESEARCH TECHNICIAN GRADE 3

required to assist with project investigating rabbit red blood cell development, with particular reference to MRNA and protein synthesis. Knowledge of protein fractionation chromatography, centrifugation and radioactive techniques is desirable. Minimum qualifications O.N.C./H.N.C. or equivalent and three years relevant experience. This post is financed by the M.R.C. until May 31, 1981. Salary on scale £3,153 per annum rising to £3,525 per annum inclusive (under review). Four weeks annual holiday. College contributory pension scheme. Apply in writing with full details to: The Head Clerk (Ref. (N) 210206), King's College London, Strand, WC2R 2LS. 9034(A)

QUEEN MARY COLLEGE
University of London
MILLIMETRE WAVE/ MOLECULAR LINE ASTRONOMY

Applications are invited for a

POSTDOCTORAL RESEARCH ASSOCIATESHIP

for work with the Millimetre Wave Astronomy Group, whose research activities involve observation and interpretation of emission from molecules in galactic HII regions and molecular clouds. The observations are made using heterodyne techniques giving high spectral resolution, from high altitude observatories in the northern and southern hemispheres. Suitable candidates would have a strong interpretational background in astronomy, or a relevant field of physical science, but applicants with more experimental experience are not excluded. The job will entail assistance in the planning and execution of the group's observational programme.

Appointment for three years from as soon as possible. Initial salary in range (under review) £3,883 to £4,382 per annum plus £450 London Allowance.

Further details obtainable from Dr J. E. Beckman (N), Physics Department, Queen Mary College, Mile End Road, London E1 4NS.

8953(A)

FELLOWSHIPS

UNIVERSITY OF WARWICK
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a one year Postdoctoral Research Fellowship in the Department of Chemistry and Molecular Sciences to work on the photochemistry of metal complexes in the solid state with Drs N. W. Alcock and T. J. Kemp. The project will involve synthesis, photochemistry and X-ray diffraction and would be suitable for someone with expertise in one of these fields (particularly the first) wishing to extend their range of skills. The post is available immediately. Initial salary will be on one of the first three points of the Research Range IA scale: £3,883 to (£4,382) to £6,555 per annum (under review). Applications (including a detailed curriculum vitae and the names of two referees) to the Academic Registrar, University of Warwick, Coventry CV4 7AL, as soon as possible. Please quote Ref. No: 18/A/78. 8957(E)

IMPERIAL CANCER RESEARCH FUND
London, England
VISITING FELLOWSHIPS

The Council of the Fund invites applications for Visiting Fellowships to be held in any of the following: the Central Laboratories of the Fund at Lincoln's Inn Fields; Mill Hill Laboratories; the Breast Cancer Unit, Guy's Hospital; Cancer Epidemiology and Clinical Trials Unit, Oxford University; Medical Oncology Unit, St Bartholomew's Hospital; or Tumour Immunology Unit, University College, London.

These Fellowships will be open to any applicant, irrespective of citizenship who has (or is about to obtain) a Ph.D. or its equivalent and who is temporarily or permanently resident outside the UK. Remuneration will be comparable with postdoctoral fellowships in country of origin; the award will be for one year. Return air fares at the lowest practicable rates will be paid for the Fellow and family, and medical insurance where necessary. The award constitutes a Contract of Service namely to undertake specified cancer studies for a stated period. Fellowships are not pensionable.

Application to the Director of Research, Imperial Cancer Research Fund, Lincoln's Inn Fields, London W.C.2, England, should be accompanied by full C.V. and list of publications, the names of two referees, an account of the applicant's current and proposed research extending to about 500 words, and a short account of the relevance of the above work to the alleviation of cancer. The laboratory or unit in which the candidate wishes to work should be specified. Closing date March 31, 1979. 9020(E)

UNIVERSITY OF SALFORD
DEPARTMENT OF CHEMISTRY AND APPLIED CHEMISTRY

Applications are invited for the following research fellowships in organic Chemistry, sponsored by the Science Research Council;

(1) Synthesis of prostanoids containing a thiophen ring, under the supervision of Dr O. Meth-Cohn and Dr S. M. Roberts, commencing April 1, 1979 or soon as possible thereafter (Ref: CH/248/N).

(2) The Chemistry of enamidines, under the supervision of Dr B. J. Wakefield, commencing June 1, 1979 or as soon as possible thereafter (Ref: CH/249/N).

Commencing salary within the range: £3,883 to £4,382 per annum; U.S.S.

Application forms are available from the Registrar, University of Salford, Salford M5 4WT (Tel: 061-736 5843, Ext. 215) to whom completed applications should be returned by February 28, 1979 for post (1) and March 31, 1979 for post (2). Please quote appropriate reference. 9012(E)

UNIVERSITY OF ABERDEEN
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH FELLOWSHIP

Applications are invited for an S.R.C. Research Fellowship working with Dr A. R. West on novel solid state energy storage systems.

Appointment will be from April 1, [illegible], or as soon thereafter as possible, and will be tenable for two years.

Salary £3,883 to £4,382 per annum on Research and Analogous Staff Range 1A Scale.

Further particulars from The Secretary, The University, Aberdeen with whom applications (2 copies) should be lodged by January 26, 1979.

9036(E)

MAGDALEN COLLEGE, OXFORD
FELLOWSHIP IN PURE MATHEMATICS

The College proposes to elect with effect from October 1, 1979 a Fellow and Tutor (male or female) in Pure Mathematics. A part-time University Lectureship is associated with the Fellowship and the successful candidate will be eligible for appointment to this post.

Completed applications, together with the names of three referees, should be submitted by February 12, 1979. Application forms and further information can be obtained from the President, Magdalen College, Oxford.

9038(E)

BIRKBECK COLLEGE
(University of London)
DEPARTMENT OF CHEMISTRY
RESEARCH OFFICER IN ORGANIC CHEMISTRY

Applications are invited for a postdoctoral fellowship to initiate a project on the synthesis of acetylenic derivatives of carbohydrates of potential biological importance. The appointment will be for one year initially, but is likely to be renewed for a second year. Salary in the range £3,685 to £4,155 (under review from October 1, 1978) plus £450 London Allowance. Applications in writing with curriculum vitae and the names of two referees to Dr N. R. Williams, Birkbeck College, Department of Chemistry, Malet Street, London WC1E 7HX.

8981(E)

COURSES

ELECTROMAGNETIC SCATTERING AND PARTICULATES

A post experience course will be held at Imperial College from March 26 to 28, 1979. Details from Dr A. R. Jones, Chem. Eng., and Chem. Tech., Imperial College, London SW7 2BY. Tel: 01-589 5111, Ext. 1906. 8980(D)

ANNOUNCEMENTS

ANNOUNCEMENT

The fourth annual "Advanced Institute in Methods of Immunological Diagnosis", conducted under the auspices of the World Health Organization Collaborating Laboratory for the Serology of Auto-immune Diseases at Wayne State University School of Medicine, will be held June 17-23, 1979. The course is to be held on the wooded campus of Cranbrook Educational Community in Bloomfield Hills, Michigan.

This year the course will emphasize selected, newer methods applicable to the diagnosis of human diseases.

Category I credit for post graduate medical education has been approved. Deadline for receiving applications is April 15. Further information can be obtained by writing to:

Noel R. Rose, M.D., Ph.D.
Department of Immunology and Microbiology
Wayne State University School of Medicine
540 East Canfield
Detroit, Michigan 48201

MISCELLANEOUS

CHINA: SCIENCE AND SOCIETY

SACU's 21 day Science Study Tour leaves March 18: an unusual opportunity to see China and study the rapidly-changing role of science and technology in Chinese society. Assess China's achievements in advanced research, the popularisation of science, and the use of 'appropriate' technology.

CHUNGKING AND THE YANGSTE GORGES

Specialist tour in August with varied coverage for Geographers and Environmentalists, visiting Peking, Wuhan, Canton and Szechuan province, whose mountains enclose the famous Red Basin, and three-day investigative trip through the Yangste Gorges.

Full preparatory study programme.

Further details: Society for Anglo-Chinese Understanding, 152 Camden High Street, London NW1 0NE. Tel. 01-267 9841. 8996(J)

STUDENTSHIPS

UNIVERSITY OF CAMBRIDGE

DEPARTMENT OF PATHOLOGY

JOHN LUCAS WALKER SENIOR STUDENTSHIP

The Managers invite applications for a John Lucas Walker Senior Studentship, the holder of which must devote himself/herself to original research in any of the following branches of Pathology (Cellular Pathology, Immunology, Microbiology and Virology). Applicants should already have completed a period of postgraduate training (Ph.D. or equivalent). Applications should be sent not later than February 19, 1979 to Professor P. Wildy, Department of Pathology, Tennis Court Road, Cambridge. The studentship is tenable for 3 years; its annual value will accord with the scales laid down for University Research Staff. 9031(F)

UNIVERSITY HOSPITAL

Saskatoon, Saskatchewan
S7N 0W8 Canada

Three-year Studentship leading to an M.Sc./Ph.D. in multi-disciplinary areas of biological psychiatry (neurochemistry, clinical chemistry, neuropharmacology) are available. Applications are invited from graduates with a first or upper second class honours or equivalent qualifications in a suitable biological subject to read for a higher degree. Interested persons should write to Dr A. V. Juorio, Head Basic Studies, Psychiatric Research Division, University Hospital, Saskatoon, Saskatchewan, S7N 0W8, Canada, including a curriculum vitae and the name and addresses of two referees. Non-Canadian applicants are advised to write before February 28, 1979, and landed immigrants to Canada and Canadian nationals before July 31, 1979. 8977(F)

UNIVERSITY OF STRATHCLYDE

DEPARTMENT OF FIBRE SCIENCE

RESEARCH STUDENTSHIPS

Applications are invited from suitably qualified science or engineering graduates for two studentships. One for work on the handle and texture of fabrics would suit a candidate with a physics/mathematics background. The other dealing with fibre structure/property relationships would suit a chemist or materials scientist.

S.R.C. scales will apply and successful applicants will be expected to register for a higher degree.

Further information and application forms can be obtained from Dr H. M. Elder, Chairman of Department, Department of Fibre Science, University of Strathclyde, George Street, Glasgow. 8999(F)

ST JOHN'S COLLEGE CAMBRIDGE RESEARCH STUDENTSHIPS

The College invites applications for a number of Research Studentships, normally tenable for three years and of such value as will, in addition to the payment of fees, bring the student's total emoluments to £1,710 a year, for men who are not already members of the College but who propose to register as Ph.D. students at the University. Candidates should have gained or have a strong prospect of gaining a first-class honours degree or equivalent.

Further details and application forms can be obtained from the Senior Tutor, St John's College, Cambridge CB2 1TP. Completed applcations must be received by April 1, 1979. 8986(F)

ASSISTANTSHIPS

UNIVERSITY OF SOUTHAMPTON

SCHOOL OF BIOCHEMICAL AND PHYSIOLOGICAL SCIENCES

GRADUATE RESEARCH ASSISTANTSHIP

Applications are invited for appointment as a GRADUATE Research Assistant in the BIOCHEMISTRY GROUP of this School, to work with Dr D. P. Bloxham on the applications of thiosulphonate reagents to problems in protein structure and function. Applicants should have a good honours degree in biochemistry or chemistry and should have an interest in enzymology. The appointment, which is S.R.C. supported, will be made as soon as possible and is initially for one year, renewable for a further two years.

The salary will be within £3,884 to £4,883 per annum (under review) on Scale 1B for Research and Analogous Staff; U.S.S. benefits.

Applications giving date of birth, curriculum vitae and the names and addresses of two referees, should be sent to Mrs P. Vaughan-Smith, The University, Southampton SO9 5NH, by January 20, 1979, quoting reference 1043/R/Na. 8889(P)

UNIVERSITY OF CALGARY GRADUATE ASSISTANTSHIPS (Teaching and Research)

Available for students proceeding to the M.Sc. and Ph.D. degrees in all branches of CHEMISTRY and BIOCHEMISTRY. **The** assistantships are valued at $7,000 to $8,000 p.a. and include remission of program fees. Travel allowance also available.

For further information write to:

Department of Chemistry
Chairman of Graduate Studies
UNIVERSITY OF CALGARY
Calgary, Alberta, Canada
T2N 1N4

Please indicate field of interest. 8969(P)

UNIVERSITY OF DUNDEE

DEPARTMENT OF MATHEMATICS

Applications are invited for a

POSTDOCTORAL RESEARCH ASSISTANTSHIP

to work with Dr D. F. Griffiths in the above Department on finite element methods in fluid dynamics. The appointment will be for two years at a starting salary in the range £3,883 to £4,382 depending on age and qualifications.

Applications, which should include a curriculum vitae and the names and addresses of two referees, should be sent by February 13, 1979 to The Secretary, The University, Dundee DD1 4HN, from whom further particulars may be obtained. Please quote Reference EST/73/78N). 9015(P)

LECTURES

1st FEBS LECTURE TOUR

A new Lectureship Programme has been started by the Advanced Courses Committee of the Federation of European Biochemical Societies. The 1st FEBS Lecture Tour will take place in 1979.

GARY FELSENFELD

(Bethesda, Md)

will lecture on

"Nucleosome Architecture and Chromatin Function"

as follows:

February 1,	London (King's College Department of Biophysics)
February 1,	Cambridge (M.R.C. Laboratory of Molecular Biology)
February 5,	Orléans (Centre de Biophysique Moléculaire)
February 6,	Paris (Institut de Recherche en Biologie Moléculaire)
February 8,	Munich (Institut für Physiologische Chemie, Physikalische Biochemie, und Zellbiologie)
February 9,	Heidelberg (European Molecular Biology Laboratory)
February 12,	Strasbourg (Laboratoire de Génétique Moléculaire des Eucaryotes)
February 14,	Barcelona (Depto. de Química Macromolecular)

8979(K)

A NATO SCHOOL ON TOPICS IN THEORETICAL ORGANIC CHEMISTRY

will be held in Gargnano (Garda Lake), Italy on June 18-30, 1979

Lectures will be delivered by:

A Bernardi (Italy)
E. Clementi (Italy)
I. G. Csizmadia (Canada)
N. Epiotis (U.S.A.)
P. von R. Schleyer (Germany)

Intending participants should contact: Professor A. Mangini, NATO School, Istituto Chimica Organica, Università, Viale Risorgimento 4, 40136 Bolonga, Italy. 8971(K)

GRANTS/SCHOLARSHIPS

MULTIPLE SCLEROSIS RESEARCH

Applications are invited for Grants funded by the Society for research related to Multiple Sclerosis. Support will be provided for approved clinical or epidemiological work as well as for laboratory-based studies within Australia.

Applications from suitably qualified persons will also be considered for Post-Doctoral Fellowships. Intending applicants for project grants should write for further information to the Executive Director, National Multiple Sclerosis Society of Australia, 616 Riversdale Road, Camberwell, 3124, Australia. Applications close on Saturday, March 31, 1979.

Professor D. R. Curtis, Chairman, Research Advisory Board, National Multiple Sclerosis of Australia. 8984(H)

TH7 ROYAL SOCIETY THE RUTHERFORD SCHOLARSHIP

This award, for graduates of e ceptional promise and ability who a under 26 years of age on May 1979, is for experimental research any of the natural sciences, with preference for experimental physics there are candidates of similar mer It will be tenable for three yeai from October 1, 1979 or such oth date as may be arranged, in son part of the British Commonweal other than that in which the applica graduated. The value, adjusted to me the circumstances, will be £2,250 p annum on appointment (under revie if held in the United Kingdom, wi allowances for travel, university fe etc. It will not normally be award to a graduate who has already held senior research award.

Applications should be made follows:

From university graduates *in t United Kingdom:* before February 1 1979 on forms obtainable from t Executive Secretary, The Roy Society, 6 Carlton House Terrac London SW1Y 5AG.

From university graduates *outsi the United Kingdom:* through th universities to the Royal Commissi for the Exhibition of 1851 on forr of application for the Commissione Science Research Scholarship to obtained from the registrars administrative authorities of th universities. 8967(H)

IMPERIAL CANCER RESEARCH FUND BURSARIES FOR TRAINING IN RESEARCH

A small number of Bursaries will be awarded at the laboratories in Lincoln's Inn Fields and Mill Hill for full-time studies leading to higher degrees in research fields relevant to cancer, that include chemistry, cell and molecular biology.

The awards will be tenable for three years from October 1, 1979 with a non-pensionable grant of £2,952 a year (subject to tax) and, in some cases, additional allowances.

Applications are invited from British subjects normally resident in the U.K. and not over 25 years of age, who hope to obtain First or Upper Second class Honours Degrees in Science in 1979.

Further details and application forms available from

The Personnel Officer
Imperial Cancer Research Fund
Lincoln's Inn Fields
London WC2A 3PX

Completed application forms should reach the Director of Research at the above address not later than February 14, 1979. 9019(H)

ALDRICH

Fieser Molecular Model Research Kit

chemistry in three dimensions

Low-cost Molecular Models — designed by Professor Louis F. Fieser.[1-4] The models consist of sturdy, color-coded plastic and aluminum parts which snap together to form bonds. They are easily assembled and handled, and may be disassembled for repeated use.

Fieser models are highly effective for assessing conformational and steric effects, and geometrical relationships.

Each kit consists of the following pieces:

- **30 tetrahedral carbon atoms (black)**
- **6 pairs of double-bonded carbon atoms (black)**
- **5 oxygen (or sulfur) atoms (red)**
- **2 trivalent nitrogen atoms (blue)**

Z10,400-0, Fieser Molecular Model Research Kit, **$18.00**

Z10,160-5, "Chemistry in Three Dimensions," by L.F. Fieser, **$3.00**

Chemistry Departments may wish to purchase quantities of atomic models to sell individually when the research kit proves too small. Hence, we also offer each atomic model in lots of 100.

Z10,401-9 100 carbon atoms (black) **$37.95**

Z10,402-7 100 pairs of double-bonded carbon atoms (black); **$69.75**

Z10,403-5 100 oxygen (or sulfur) atoms (red) **$19.35**

Z10,404-3 100 nitrogen atoms (blue) **$29.25**

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,** 1 (1975) and **264,** v, 11 Nov. (1976)

Continuous cell lines with specific killer T-cell activity — *R. DiPauli and R. Langman* 134

Effects of *S*-lactoylglutathione and inhibitors of glyoxalase I on histamine release from human leukocytes — *E. Gillespie* 135

The influence of thymus on the development of MHC restrictions exhibited by T-helper cells — *H. Waldmann, H. Pope, C. Bettles and A. J. S. Davies* 137

Localisation of intestinal gastrin in a distinct endocrine cell type — *A. M. J. Buchan, J. M. Polak, E. Solcia and A. G. E. Pearse* 138

Smallpox: ignorance is never bliss

IGNORANCE confronts ignorance in the case of the release of the smallpox virus, *Variola major* Abid, from a Birmingham University laboratory last August. Clive Jenkins, leader of the Association of Scientific, Technical and Managerial Staffs (ASTMS), a trades union taking an increasing interest in laboratory safety in the UK, 'published' the confidential Shooter Report on the Birmingham affair last week. This has removed our ignorance of the events which led up to the smallpox release, as we describe in the next few pages; but it has not removed our ignorance of the smallpox virus, whose relationships among its many strains and to the various animal poxes—from which it might re-emerge—remains obscure. Professor Henry Bedson was working on the protein characterisation of the various pox viruses, under pressure from the forthcoming closure of his laboratory, when the escape occurred. The World Health Organisation (WHO) team, whose work has led to the virtual eradication of *Variola major* as a cause of disease, had earlier in the year described his work as "fascinating", but within a few weeks Professor Bedson had committed suicide.

Professor Bedson, the Shooter Report implies, had been guilty of his own kind of ignorance: wilfully or otherwise he had ignored elementary safety precautions in the handling of the virus. According to one member of the Dangerous Pathogens Advisory Group (DPAG), which licensed Bedson's laboratory as adequate in 1976, the equipment Bedson was using was unsafe "except for the mildest pathogens". Interestingly enough, the first this DPAG member had seen of the apparatus was on television news last week.

None of these various kinds of ignorance is tolerable. First we must know more of the smallpox virus and its relatives. Second, those working with pathogenic—or potentially pathogenic—organisms must be prepared to educate themselves about the mechanisms by which those organisms can escape. (This involves as much physics as biology). And third, after DPAG is disbanded (it must be, if only to restore public confidence), its successor must be provided with sufficient critical investigative power that its members do not have to rely on the television for their information.

Most of what needs to be done follows from these three requirements. First, Professor Dumbell, whose laboratory at St Mary's Hospital is the only one to retain smallpox virus in the UK, must be given the means to continue his work (the characterisation of pox viruses by their DNA content). It is not reasonable that he should be hounded into a two-year hiatus in his work because of the laxity of another laboratory. The World Health Organisation, which suffered no strictures in Shooter for its inspection procedures, has designated Dumbell's laboratory as one of the only four in the world that can continue to work on smallpox. He should be able to continue. But perhaps he should be prepared to take up the offer, reported below, of the director of the special pathogens unit at Porton Down, Dr David Simpson, to store his smallpox samples at Porton (whose containment facilities are second to none) and provide him with laboratory space. This would imply that Professor Dumbell's work could continue soon, but in collaboration with Porton staff; and that his animal pox samples—which are not so virulent as *Variola major*—would remain at St Mary's. Such an arrangement might prove an effective compromise, if logic rather than emotion prevails.

Second, the need for improving safety measures and safety education at other laboratories holding category A pathogens (and for that matter the milder category B pathogens too) leads to a number of consequences: that money should be made readily available for increasing laboratory safety (it has not been easily available in the past); that safety officers be provided with sufficient status that they can confront heads of departments on equal terms; and that (we shall argue) a body be set up to provide education and research into biosafety.

That safety money has not come easily in the past is illustrated by the comment, only last week, of Professor Arie Zuckerman of the London School of Hygiene and Tropical Medicine that he could not afford the six white coats per staff member recommended in the Godber report (the result of an inquiry which followed a smallpox outbreak at the school in 1973). Presumably, in the present political climate, money should present no problem. But it must be provided in such a way that there is no conflict of interest over its spending. If it were provided, for example, by the Medical Research Council (MRC), which funds biomedical research, there would be a regular conflict over how much to spend on research and how much on safety. Again, if that money were provided as a block grant to a head of department, there might be an accounting difficulty in determining whether the money had finally been spent on safety or on some other matter. The best solution would seem to be money provided either by the ministry concerned (the Department of Education and Science for universities and the Department of Health and Social Security for hospitals) or better directly by the Health and Safety Executive (HSE) to the safety officer of each laboratory. Then the conflicts of interest in the giving and the spending of money would be minimised.

Status for the safety officer is a thornier problem. It is not merely a matter of equal salaries, but one of prestige, age, and personality. There must be a mutual respect for their individual concerns between the head of department and the safety officer, the one for the academic advancement of the department, the other for the human welfare of its members. Probably the most experienced and knowledgable biosafety officer in this country, Dr Mark Darlow (who was head of the safety section at Porton from 1951 to 1976), believes that the job involves being "a kind of uncle". He is a doctor of medicine, and has something of the manner of a general practitioner—firm yet sympathetic—and believes it vital that a safety officer gets to know the families of the people in his care, and their doctors. He has all the assurance of the medical profession, and one can be quite sure he had the confidence to confront the director of Porton and its scientists when it was necessary. And he was successful, despite the awesome panoply of bugs (from smallpox to plague) that Porton carried. There were very few incidents, and those only due to inevitable human frailty. It is dangerous to argue from one case; but there *are* very few; and it seems reasonable to suggest that a safety officer should always be a doctor. This gives him or her the status and confidence of the profession, and ensures the right motivation; safety is not a business for failed academics.

This leads to the next matter—the need for education and research in biosafety. Darlow's confidence rests not only on his professional sangfroid but also on experiment. In very early days at Porton, for example, he discovered the hardiness of the smallpox virus. He found that it can survive in dust in the corners of rooms, in pockets, even in dust on the top of a fluorescent light. He did experiments with high speed cinephotography on pipetting, and showed that a cloud of tiny droplets floats into the air with every drop released. He had the confidence of facts, and could convince the scientists in his care with evidence. No scientist is going to accept arbitrary controls; there must be adequate reason.

Not only is there now very little research being done (whereas as great deal remains to be learned), but what is known is not widely disseminated. As Dr Darlow wrote prophetically in 1969 "The literature on the subject is in fact very extensive, but many of the publications have appeared in unfamiliar journals and have consequently been overlooked; it is to be regretted that the spilling of ink is so inaudible and that positive action is only stimulated by the resounding spilling of pathogens." (*Methods in Microbiology* vol 1 ch 6; 1969.)

Biosafety is peripheral to the interests of an ambitious academic, and he or she is not going to spend as long reading the safety literature as reading the latest development in his or her field. That much is inevitable. Neither is such a person going to spend much time researching hazards, the reward for which is a human one quite different from the pursuit of academic success. It is therefore necessary to set up a new institution, with its own career structure and motivations, with the objective both of disseminating existing scientific knowledge on biosafety, and, most important for maintaining the liveliness of the body, with the objective of pursuing research into biosafety questions. There are many of these, and not only concerning work with known pathogens; there is a great deal yet to be learned about the safety of work with recombinant DNA, for example.

Further, since one product of such a unit would certainly be ideas for new devices to increase containment and ease research, and since such devices will be in demand, the unit could even generate some of its own income through patents and licensing. If Britain moved fast enough, such a body could become a world leader in the field whose prestige would make it easier to attract the right kind of talents to it: talents in education, medicine, biology, physics, and commerce. The Secretary of State for Education and Science, Mrs Shirley Williams, who recently indicated her willingness to invest large sums of money in research into the hazards of genetic engineering, would be well advised to consider setting up such an institution. It would be an innovation. None yet exists quite like it; neither the National Radiological Protection Board, nor the laboratories of the Health and Safety Executive, nor the research units of the MRC, have such conjoined functions; but the functions must be conjoined as each activity would stimulate the others. Alone, each is a stranded whale.

After continuing research into smallpox; after removing ignorance of biosafety; the third matter we raised was the question of keeping DPAG's successor properly informed. Of course that in itself is not enough: DPAG proved itself unwilling to act. But a dose of 'public interest' and union representation, as on the Genetic Manipulation Advisory Group, should soon cure that. DPAG already had teeth, under the Health and Safety at Work Act; its advice had to be accepted or a laboratory would have to close. Its successor needs no more than that—except information.

DPAG was not well informed. It has emerged now that there is no complete and guaranteed list of the laboratories holding category A pathogens, let alone category B. The Godber working party, which defined the categories, sent out a large number of questionnaires concerning pathogens held to as many laboratories as they could think of. Of 4,016 laboratories questioned, 2,152 did not even reply. Perhaps they held no pathogens; but there is no guarantee of that. Further, DPAG has had only one full time inspector, a retired member of the Public Health Services Laboratory, plus two occasional assistants, to inspect the 115 laboratories holding category A pathogens that *were* unearthed by Godber. At Birmingham, according to Shooter, the DPAG inspectors failed even to consult a checklist of items recommended by the Godber report.

The Health and Safety Executive has a special unit of three microbiologists, but that is less than a year old and is now occupied full time until April inspecting 11 laboratories holding category A human pathogens. (Incidentally DPAG has reduced the list of 12 category A human pathogens defined by Godber to 5, while adding 4 new ones.) This same HSE team also has the duty of inspecting laboratories for the Genetic Manipulation Advisory Group. It is clearly overstretched, and must be expanded by a large factor. But there is another problem: where are people of sufficient quality and knowledge to be found? The HSE function must not be one of rubber-stamping, of accepting the assurances of the 'expert' at the laboratory who rarely turns to the biosafety literature. There may be no more than half a dozen people in the country who really understand the field. These people must be brought together as a matter of urgency, first to assist in training new inspectors for the HSE and second to advise on the setting up of the biosafety research and education unit we recommend. Ultimately that unit can become the source of new inspectors and of biosafety officers.

Finally, there is the question of the need for another public inquiry, as demanded by Mr Clive Jenkins. Our view is that would only confuse a situation where a laboratory is already littered with the recommendations of well-meaning committees. The Godber working party was set up five years ago to clarify the situation and that it did. The failure has been to implement its recommendations properly, which is a failure of government. DPAG should be reconstituted along the lines of GMAG. The HSE microbiological inspectorate should be significantly strengthened. A biosafety research and education unit should be set up. And a way should be found to enable Professor Dumbell to continue his smallpox work rapidly, probably at Porton. These are the ways forward from Birmingham. ☐

On 24 August last year Professor Henry Bedson of the Department of Medical Microbiology at Birmingham University analysed samples from Mrs Janet Parker, a university photographer, and confirmed that she had smallpox. The source of her infection was almost certainly Bedson's smallpox laboratory. Within a few weeks Professor Bedson had committed suicide and Mrs Parker had died. The affair is *sub judice* under the pending court case against Birmingham University under the Health and Safety at Work Act, but despite that Clive Jenkins, leader of the Association of Scientific, Technical and Managerial Staffs last week published his copy of the Shooter report—the confidential government report of the committee of inquiry into the incident. Shooter's indictment is a strong one, and Mr Jenkins believed it in "the over-riding public interest" that he publish it. Here Robin McKie of the *Times Higher Education Supplement*, Mary Lindley, Judy Redfearn and Robert Walgate report.

UK smallpox research could continue at Porton

The unofficial publication of the Shooter report by union leader Clive Jenkins last week is likely to produce swift results in Britain. The recommendation that the nation's only remaining smallpox research unit, at St Mary's Hospital in London, should be moved to an isolated area in the country has already been backed by the local Member of Parliament, Mr Arthur Latham. And the head of the unit, Professor Keith Dumbell, admitted that it would now be impossible for smallpox research to be carried out at St Mary's.

However, later in the week Dr David Simpson, recently appointed director of the special pathogens unit at the Medical Research Establishment, Porton, told *Nature* that he would be willing to receive Professor Dumbell's live smallpox virus at Porton. He could store it there, said Dr Simpson, but he did not want Porton to become "just rent-a-space". Any researcher using Porton in this way would be expected to use and collaborate with Porton staff in research on the material so stored.

Professor Dumbell, on the other hand, believes the scientific case for moving is arguable. "We have in our laboratory all the precautions that we have been able to think up. The chances of a virus escaping are very much smaller than those risks to which we expose ourselves everyday", Professor Dumbell added.

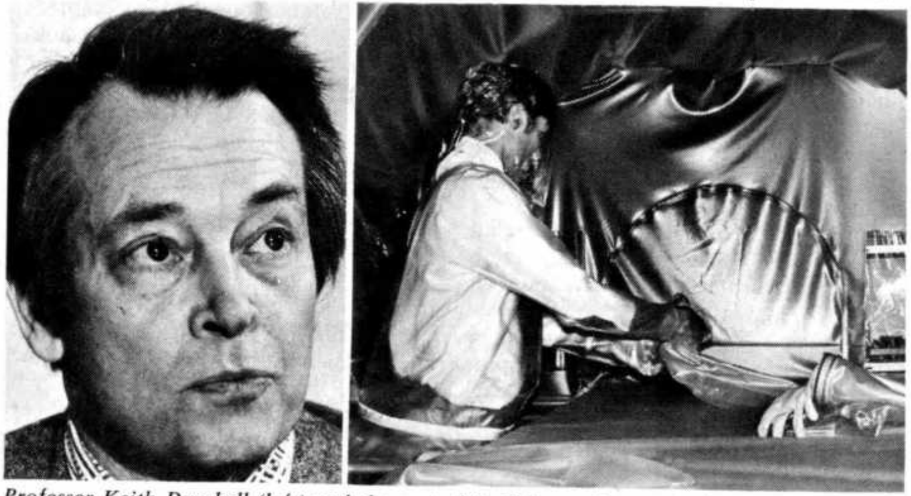
His laboratory was a purpose-built unit designed to cope with smallpox research and took two years to set up. The safeguards—in contrast to the inadequate measures disclosed at Birmingham—include a sealed anteroom; effective laboratory air filtration; antiseptic disposable clothing; a shower room; and regular vaccinations. The move to the country would cost two years' effort that could otherwise be used for smallpox research, he stated.

If the smallpox laboratory at St. Mary's had to close it would be for political reasons, added the school's dean, Dr Harold Edwards. The move to the country would only serve to isolate the smallpox resarchers from colleagues involved in similar areas of work. And Dr Edwards warned that the controversy surrounding the Birmingham smallpox outbreak could lead to growing demands for tighter controls which would diminish the quantity of scientific research in Britain. "The trouble is that increases in controls are not followed by the necessary increases in public funds. Something else has to be taken out of research funds to achieve new safety standards".

Professor Dumbell, who supplied Professor Bedson at Birmingham with 22 virus strains including the one which killed Mrs Parker, admitted there had been a misdemeanour involved when they did not inform the Dangerous Pathogens Advisory Group (DPAG) of the transfer. He thought both of them had assumed the other had notified the group.

Professor Bedson and Professor Dumbell were working on parallel lines of research. At Birmingham, Professor Bedson was using the protein coats of viruses as the basis of an identification process, while Professor Dumbell was attempting a similar technique using the DNA of viruses.

Asked if Professor Bedson could have carried on his work at St. Mary's instead of rushing to complete it at Birmingham, Professor Dumbell said that when the World Health Organisation indicated it was to close down all smallpox research units in Britain, apart from the one at St Mary's, he had been asked by the researchers if he would provide space for them to continue their work. "I answered that I was prepared to do this". □



Professor Keith Dumbell (left) and the sort of facilities at Porton (right) with which he could continue smallpox research.

How the virus escaped

THE Birmingham smallpox laboratory which was the source of the infection which killed Mrs Janet Parker, is a tiny, eight-foot square room in the east wing of Birmingham University's medical school. It is surrounded by a larger room in which experiments on animal pox viruses were performed. Both rooms contain equipment used in normal microbiological research, including safety cabinets with air filters, centrifuges and autoclaves for sterilising gowns and equipment.

The Shooter committee firstly found there was no evidence that Mrs Parker had ever been in the pox virus labora-

0028-0836/79/0277—0077$01.00

tory suite and they concluded that the virus must therefore have escaped from the smallpox room. The group then discovered that not all smallpox work had been carried out inside the room's safety cabinet and some work with an aspirator to suck off fluid from cell cultures had been undertaken on an open bench.

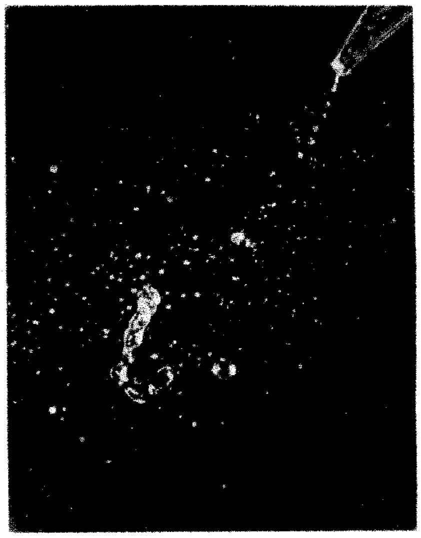
The principal means of transmission of smallpox viruses is probably by aerosol, in tiny droplets of fluid that form when a pipette is used to deliver drops onto a gel or whenever there is splashing of fluid containing the virus. According to Dr Mark Darlow, head of the safety department at the Porton germ warfare establishment for 25 years, the virus is also very stable; so that once airborne it is a potential killer. An efficient air withdrawal and filtration system over any experiment is therefore essential. But many academics still believe that "what was good enough for Pasteur is good enough for me", said Dr Darlow last week.

According to the Shooter report "the opening and closing of the smallpox room door and the passage in and out by whoever was conducting work on the virus would have created the opportunity for any airborne virus to escape into the animal pox room".

The consequent danger was made all the worse because gowns worn in the smallpox room were not removed on leaving.

Even more seriously, the service ducts in the animal pox room and the smallpox room both had gaps which could allow the leakage of viruses. In particular, the telephone room above, which was connected by the duct to the animal pox room, was used frequently by Mrs Parker, when she was telephoning suppliers to order photographic materials. "A check of the orders placed by Mrs Parker during this period reveals that on 25 July she placed an unusually large number of orders. The relevant strain of smallpox virus, Abid, was being handled in the smallpox room on July 24 and 25", the report states.

The committee, although not certain by what route Mrs Parker was infected, concluded that escape via the service duct in the animal pox room was therefore the most probable route of escape of the virus. However, the virus could have reached the corridor outside the laboratory suite and Mrs Parker could have been infected when visiting the inquiry office or the darkroom at the end of the corridor. This was a less likely route, though, and was used by many other persons.



Society for Applied Bacteriology

An aerosol resulting from a bubble burst at a pipette tip when the last drop was expelled. This explains how smallpox virus might have escaped into the air.

And although they could not be certain about the exact route, the Shooter committee was certain that a combination of poor laboratory procedures, amounting to a major breach in containment policy, was responsible for the outbreak. □

All safety nets failed, says Shooter

The report of the Shooter inquiry into the causes of the smallpox outbreak in Birmingham last year finds fault with the three major organisations—the Dangerous Pathogens Advisory Group (DPAG), the World Health Organisation (WHO) and Birmingham University—which were concerned in some way with either running or monitoring the smallpox laboratory at the Department of Medical Microbiology at Birmingham University.

DPAG

The Dangerous Pathogens Advisory Group (DPAG) exists precisely to prevent the sort of event which occurred at Birmingham. It was created in 1975 in the wake of a previous outbreak of smallpox from a laboratory in London in 1973. Shortly after it came into being it began to formulate a code of practice for work with category A pathogens—those recognised as the most dangerous—and to inspect all laboratories known to hold them.

In February 1976, DPAG's inspector visited the Birmingham laboratory. During the time he was there, says the Shooter report, no work on smallpox was being done. He tested the airflow through the safety cabinet and then spent most of his visit talking to Professor Bedson about smallpox work.

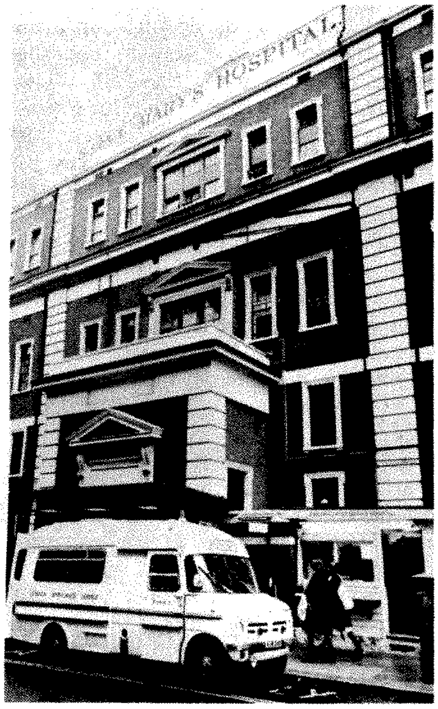
The Shooter report criticises the DPAG inspector for not finding out enough about the "range and extent of the work being done". He did not, says the report, "ask about work with tissue cultures"; neither did he ask about the methods of harvesting virus. "These points seem to us to be of considerable importance", the report goes on, "since one of the unsatisfactory features . . . was the necessity to pass in and out of the smallpox room during the course of work with smallpox to place cultures in the incubators and to use the low speed centrifuge".

Despite the fact that the Birmingham lab lacked some of the facilities then recommended for use with category A pathogens, namely an air lock, shower, changing facilities and double autoclave, the DPAG inspector recommended to DPAG that the laboratory be approved. He based his judgement on Professor Bedson's reputation as an "experienced and safety-conscious virologist" and the fact that the few named people working on smallpox always did so under Bedson's supervision. There was also a "highly efficient vaccination programme" in force.

When DPAG came to discuss the inspector's report (it meets twice yearly) it felt that it could use its discretionary powers—granted to it when it was created—to recommend approval of the laboratory to the DHSS despite the shortcomings. It added, however, that "fresh clearance should be sought in the event of significant changes in staff, facilities or work programme".

The committee of inquiry felt that the inspector's report did not give DPAG sufficient information on which to base a recommendation. It criticises DPAG for not insisting on an inspection report that compared the facilities and procedures with those laid out in its own safety code and recommends that in future DPAG inspectors should compare laboratories' facilities against a detailed check list. It also criticises the way in which DPAG exercised its discretionary powers and recommends that in future "discretion should be exercised by DPAG only if alternative arrangements are in force in a category A laboratory which are able to achieve a degree of safety equivalent to that specified in the safety code."

Since the inspection in 1976, says the report, changes had taken place in the smallpox laboratory. Professor Bedson had ceased to do experiments because of other commitments and most of the work had been taken over by a PhD student. This had not been explained to the DPAG inspector. In addition



St Mary's Hospital, London which houses the UK's only smallpox laboratory.

the volume of work increased. Twenty two additional strains of variola virus were delivered to the laboratory in early 1978.

DPAG, says the report, was notified of none of these changes. The report therefore recommends that as well as notifying DHSS of any changes, category A laboratories should be reviewed annually. It also suggests that notification of intention to hold category A pathogens should be compulsory and that DPAG should start inspecting all other category A laboratories immediately. Finally, it says, the need to work with variola virus in the UK should be reviewed. If it is decided that work should go on, then, the report recommends, the one remaining laboratory in the UK holding the virus, at St. Mary's Hospital, London, should be moved into the country.

Birmingham University

Birmingham University and the Department of Medical Microbiology both had safety policies at the time of the smallpox outbreak which should have had some influence on the way research on smallpox was conducted. The committee of inquiry found, however, that there was no "effective system of determining whether both . . . safety policies were being regularly implemented".

The responsibility of putting the safety codes into practice rested with Professor Bedson as head of department. Responsibility for formulating the safety code specific to microbiological research, however, rested with the committee for the control of pathogenic organisms and infectious materials (CCPOIM), a subcommittee of the university's central safety committee, whose members came solely from the academic staff.

Since the inspection of all departments working with microorganisms by CCPOIM in 1975 there had been no further inspections, says the report. It therefore recommends that "expert safety inspections" should be carried out regularly. It also suggests that a head of department should not be a "member of the team that inspects his own department" (in 1975, Professor Bedson's had been one of the inspecting team), and that the membership of the CCPOIM be extended to include members of the non-academic university staff.

The committee of inquiry also found the experience of the staff working in the smallpox laboratory lacking. Apart from a technician who had worked with smallpox for 11 years and had been trained by Professor Bedson, the other people working on smallpox were a former PhD student, who joined the laboratory in 1974, and a trainee technician who had been working at the lab for about a year. "As far as we know", says the report, the former PhD student "was never formally trained in the special precautions required for work with smallpox viruses". The trainee technician, who joined the lab straight after leaving school, had apparently started working with smallpox virus "only nine months after she had joined the laboratory".

The report says that this state of affairs was inadequate. It recommends that the university review its policy for instructing staff in laboratory techniques and safety precautions and that it ensures that "the staff are not permitted to carry out such work without appropriate . . . supervision".

WHO

The WHO had been corresponding with Professor Bedson about safety without the knowledge of either the Birmingham University authorities or the DHSS.

"It is anomalous", says the report, "that though WHO had decided the work could not be supported after the end of 1978 this was not communicated to DHSS or the university". It recommends that in future "institutions should ensure that all dealings with outside bodies concerning work with safety implications in their departments are monitored by the central administration. . . ." Its recommendation to the WHO is that it should "maintain a closer liaison with the responsible government authority regarding its dealings with category A pathogen laboratories and in particular with regard to the safety of those laboratories". ☐

WHO had serious doubts on safety in smallpox lab

WHEN Mrs Parker contracted smallpox, Professor Bedson and his researchers at Birmingham were working under considerable pressure. They wanted to complete their programme of research on smallpox virus by the end of 1978 when their laboratory was due to close.

The 1978 deadline for the completion of the smallpox work had been decided in 1977 when the World Health Organisation (WHO) informed Bedson that his laboratory had not been chosen as a WHO Collaborating Centre for Poxvirus Research. "It was felt", said the WHO in its letter to Bedson on 16 September, 1977 informing him of its decision, "that . . . the creation of another official centre would give the impression that WHO is itself increasing the danger of laboratory accidents. . . ." In spite of this decision, however, the WHO went on to say that the work at Birmingham was "extremely important and should be supported". It promised Bedson a $7,500 grant for 1977.

In his reply of 4 October, Bedson described the news that his laboratory was not to become a collaborating centre as "a bit of a bombshell". The policy of the UK Department of Health and Social Security (DHSS) was that smallpox research in the UK should only go on in official WHO centres. The implication, therefore, was that Bedson's lab would have to close. This would mean that the work would now have to be done on a shortened timescale, wrote Bedson. "If pressed for a date", he went on, "I would have thought that we should aim to complete our studies with smallpox/whitepox viruses by the end of 1978".

After the WHO's response of 18 October agreeing to Bedson's plan there was a pause in correspondence until late February 1978. From then until 24 August, the day Mrs Parker's illness was diagnosed, all correspondence concerned the visit by WHO inspectors to the Birmingham laboratory on 4 May.

Before the visit took place, Bedson was eager to point out that the Birmingham facilities in no way matched those set out for the WHO's definitive smallpox labs. "It would be expensive and very costly in time", he wrote on 31 March, "if we were to try and establish such a laboratory and quite unjustified in view of our projected halt to the smallpox/whitepox work at the end of the year". Dr I. Arita, chief of the WHO's Smallpox Eradication Unit in Geneva, assured Bedson that the expected benefit of his study "far exceeded the minimal risk" currently present in his laboratory and that the visiting team would understand his situation.

The three inspectors, however, were very critical of the safety precautions taken at the laboratory. They recommended that all mouth pipetting be prohibited, that back fastening gowns which would remain in the laboratory be worn, that hypochlorite solution be used as a permanent barrier in sinks and that gloves be worn for all work with infectious materials.

On 2 June Bedson replied to these criticisms. He accepted the suggestions concerning the use of hypochlorite solution and the wearing of gloves but argued that mouth-pipetting had not been used with smallpox for ten years. The WHO team had observed a 'temporary aberration' which would not happen again whereby mouth-pipetting was used in connection with an animal poxvirus. He also argued that back fastening gowns were used in the smallpox lab and not in the animal pox lab so that they could be distinguished.

One inspector, however, was not satisfied He was concerned about the lack of a shower, the lack of secondary containment in the animal poxvirus lab where smallpox viruses were stored and the performance and maintainence of the biological safety cabinet in the smallpox room. He recommended that the laboratory be upgraded to meet the WHO standards or "discontinue work with variola at the earliest possible date".

The next letter Bedson wrote was on 24 August when he returned from holiday. Later that day he was to find brick-shaped particles characteristic of poxviruses in vesicle fluid specimens from Mrs Parker but at the time he wrote the letter smallpox had not been diagnosed. "There is no question", he wrote, "of our being able to upgrade our facilities to meet the full WHO standards and we are therefore proceeding with our plans to complete our studies with varola/whitepox virus by the end of this year".

What Bedson seems to have never mentioned in any of his correspondence was that the amount of smallpox work in his lab had actually increased substantially. In his letter of 2 June, he even says that there had been "a progressive decline in the scale and diversity of our operations, particularly since 1973". The Shooter inquiry found otherwise. In particular shortly after Bedson wrote this letter the rate of work increased even more as work began on 22 variola strains received from St. Mary's Hospital, London, on 26 May. Dr Mary Darlow, ex-safety officer of the Porton germ warfare establishment, commented last week: "Bedson knew he was backing a lame horse and that it would stumble sooner or later. It stumbled sooner". □

Bedson's concern: could smallpox re-emerge?

RIFT valley fever is a cattle disease with a mortality rate of 80%. It is endemic in Egypt and recently has begun to affect man. The Egyptian authorities estimate that 18,000 people have so far caught the disease but, according to Professor Arie Zuckerman of the London School of Hygiene and Tropical Medicine (LSHTM), a team from the school which recently visited Egypt puts the number at nearer 200,000. Without suitable facilities for diagnosis and research, says Professor Zuckerman, it would be difficult to see how the spread of Rift valley fever could be prevented in Europe once the disease had crossed the Suez canal.

The situation with other diseases is similar. Early diagnosis of rabies or new diseases such as lassa fever or Marburg disease means that they can be contained. Having suitable research facilities means that vaccine and treatment can be developed in case of an outbreak.

Research is also important, however, for predicting new diseases. In the case of smallpox, for example, eradication was possible because of the existence of a very effective vaccine and because it appears to have no animal reservoir or insect vector. What worries microbiologists now, however, is that poxviruses very similar to the smallpox virus which currently affect only animals may begin to affect humans. Research on the similarities between different poxviruses and their relationship to smallpox might therefore indicate how likely this is.

The first poxvirus to be identified in a non-human primate was monkeypox virus which was isolated in 1958. Since then it has been isolated from non-human primates on several occasions and has been responsible for about 30 cases of human monkeypox in West and Central Africa between 1970 and 1978. Fortunately the spread of human monkeypox from man to man is extremely rare.

Another poxvirus very closely related to smallpox is whitepox. It was first isolated from the kidneys of cynomolgus monkeys in 1964 and it is still impossible to distinguish it from smallpox virus by laboratory tests.

The work at Birmingham centred on the identification and differentiation of poxviruses. Early work had tried to distinguish viruses by looking at the enzymes they produce. More recent work, however, had used a technique called polyacrylamide gel electrophoresis (PAGE) to separate out the polypeptide constituents of viruses and then compare them.

By mid-1978 the Birmingham team had completed comparisons of 41 different poxviruses using PAGE techniques. It had found that all but three could be put into one of four basic categories. The smallpox/whitepox category of viruses could be subdivided into types A and B. When a report of the findings was written for the WHO much more work was planned on the differentiation of types A and B smallpox viruses. Most of the B viruses seemed to be of Middle Eastern or Pakistani origin whereas the A viruses had mainly originated in Africa. Whitepox viruses were also found to subdivide into types A and B, the B type originating in Asia and the A type in Africa. "This supports the view", said the report "that these (whitepox viruses) must be regarded as smallpox viruses".

After the extensive study of smallpox/whitepox viruses which was to have finished at the end of 1978, the Birmingham laboratory was planning to continue its study of animal pox viruses Minor differences had been observed between some of the cowpox-like viruses and some of the monkeypox-like viruses, said the report, and those should be the subject of further study.

- The WHO says that to the best of its knowledge the only laboratories holding smallpox viruses are the following National Institute for Virology, South Africa; Centre for Disease Control, Atlanta, USA; American Type Culture Collection, New York, USA; Walter Reed Army Institute of Research, Washington, USA; Bayerische Landesimpfanstalt, Munich, West Germany; Institut fur Schiffs und Tropenkrankheiten, Hamburg, West Germany; Rijks Institut voor de Volksgezondheid, Bilthoven, Netherlands; Laboratory of Smallpox Prophylaxis, Research Institute of Viral Preparations, Moscow, USSR; Virology Department, St Mary's Hospital Medical School, London, UK; Institute for Control of Drugs and Biological Products, Peking, China. □

Health in the laboratory

FOR more than 20 years both government and unions have been concerned about standards of safety in British laboratories and the health of people working in them. The first major stimulus came in 1957 when D. D. Reid, of the London School of Hygiene and Tropical Medicine (LSHTM), reported that the incidence of tuberculosis among medical laboratory workers was higher than expected. As a result, a working party of the Public Health Laboratory Service (PHLS) made recommendations for safe working in laboratories handling tuberculous material. These were revised in 1968, but adverse reports continued to appear sporadically, and in 1970 the Department of Health and Social Security (DHSS) commissioned a full investigation from the Trades Union Congress (TUC) Centennial Institute of Occupational Health at LSHTM. This was carried out between 1971 and 1974 and the full report results appeared as a thesis in 1975. As far as the author is aware, the DHSS has done no more than file the report.

The investigation included retrospective surveys of the incidence of four infectious diseases and the standards of health care and safety in the laboratories of the National Health Service (NHS, consisting of hospital laboratories), the National Blood Transfusion Service and the PHLS (Harrington, J. M., & Shannon, H. S. *Brit. Med. J.* **1**, 759; 1976). The surveys involved 24,000 workers, constituting 85% of the total in those laboratories. The results for the infectious diseases are summarised in Table 1.

The totals for tuberculosis in England and Wales and in Scotland represented, respectively, a 5.4 and a 4 2 times greater risk of acquiring the disease among laboratory workers than the general population. It was not possible to make a similar assessment for the other infections, but the conclusion was that hepatitis possibly remained an occupational hazard for laboratory workers, while shigellosis may have been more prevalent among them than among the general population. All four diseases seemed most likely to afflict technicians

Variable standards of safety and health care were reported (Harrington, J. M. & Shannon, H. S. *Brit. med. J.* **1**, 626; 1977). Less than half of the laboratory workers had been examined medically before employment and a similarly small proportion had been offered vaccination. The length of service of the workers indicated that the standards had not improved during the previous 10 years and had probably deteriorated Scottish laboratories proved to have a slightly better record in safety control than their English and Welsh counterparts, and PHLS laboratories did better than those of the NHS, providing more formal safety training.

Mouth pipetting was still being practised in 65% of English and Welsh laboratories and 28% of Scottish laboratories. Although protective clothing was usually available, its use was compulsory in only one third of English and Welsh laboratories and two-thirds of Scottish laboratories, even when procedures involved were known to be hazardous. The servicing of safety cabinets was inadequate in two-thirds of Scottish laboratories and 40% of English and Welsh laboratories, and known carcinogens were still being used in a small proportion of laboratories.

Another phase of the investigation involved a prospective survey of accidents and absence from work due to illness in 10% of the laboratories surveyed previously (Harrington, J. M. MD thesis Univ. London, 1975). Between April 1973 and March 1974 records were kept for 2,520 workers in 39 laboratories. Absence was generally lower than in other British industries. The only possible sign of a link with occupational hazards was provided by infectious and parasitic diseases, which constituted the chief cause of absence.

During this phase of the investigation 627 accidents caused injury in the 39 laboratories and one in four of the workers was affected. Technicians—64% of the population—suffered 76% of the injuries, including all nine of those due to mouth pipetting. The most common injuries among all groups of laboratory workers were lacerations, splashes and burns to the hands or eyes, most of them relatively trivial.

The remaining phase of the investigation was a retrospective study of mortality among 156 pathologists (dying between 1955 and 1973) and 154 medical laboratory technicians (dying between 1963 and 1973) (Harrington, J. M. & Shannon, H. S. *Brit. med. J.* **4**, 329; 1975). Both populations experienced lower mortality than the general population, as would be expected because any occupational group is likely to be healthier than the whole population.

The only examples of higher incidence among the laboratory populations were for lymphoma and leukaemia, which killed eight male English pathologists compared with the expected 3.3, and suicide which in England and Wales was the cause of death in nine male pathologists. compared with the expected 3.4, and nine male and six female technicians, compared with the expected 4.7 and 1.5, respectively. Suicide proved to be the commonest cause of death among English female technicians. Their easy access to poisonous chemicals was thought to be the most likely explanation. ☐

Table 1 Infectious diseases in laboratory workers in England and Wales in 1971 and Scotland in 1973.

Infection	Medical staff	Scientific staff	Technical staff	Other	Total
Tuberculosis	1 (1)	1	14 (2)	2	18 (3)
Hepatitis	2 (1)	1	27 (2)	5	35 (3)
Shigellosis	1	3 (1)	29 (7)	4	37 (8)
Brucellosis	–	–	1	–	1

Reports by David Dickson

AAAS president calls for closer university/industry links

WITH US industry under pressure to remain competitive, and universities facing problems in securing research support from conventional sources, the time has come for a closer relationship between the two, according to Dr Edward David, president of the American Association for the Advancement of Science.

Close links between the industrial and academic communities could help to preserve important features of the research system: a pluralism of funding sources, leading to greater local autonomy in the conduct of research and development programmes; a more competitive environment, based on technical excellence; and a dependence on "high achievers" able to provide scientific leadership.

If basic research was defined not as research carried out with no particular goal in mind, but rather as any research leading to a greater understanding of natural and social processes, regardless of the motive, then the amount of such research being carried out by industry was larger than current definitions indicated. Industry had also widened its research interests beyond just improving the technology of production lines. "Today there is a much broader point of view, ranging from the sociology of customers, to research on the R&D process itself." Industrial research was increasingly using the basic research paradigm in forwarding its function, and it would not be incompatible to couple this directly with academic interests.

In the 1950s and 1960s, industry support for university research had been primarily philanthropic in nature. Now a number of companies were exploring ways of setting up long-term cooperative arrangements with universities. "Ten years from now I expect to see a vigorous community of industrial/academic scientists, with academics providing the ideas and industry providing the vehicle for their commercialisation. This will certainly be an improvement on the situation that we have now. And it will be more in keeping with the situation facing both sides in the 1980s." ☐

US to brief scientists on human rights

THE US State Department is preparing briefing materials for scientists and others who participate in official exchanges, describing the goals and objectives of the US human rights policy, and responding to questions about the legality and safety of activities in defence of colleagues abroad.

Mrs Roberta Cohen, of the Department's Bureau of Human Rights and Humanitarian Affairs, told a session on international freedom and responsibility that US Government agencies and representatives had been instructed not to discourage or prohibit exchange participants from contacting private Soviet citizens. "We in the Bureau of Human Rights take it as an obligation of the Government to correct any wrong impression created that it is seeking to discourage scientists on exchange programmes from efforts to defend foreign colleagues," she said.

The Government asked only that contacts of potential sensitivity, particularly in tense periods, be discussed in advance with Administration officials, "in order to ensure that American scientists involved have full information assessing the potential risks".

A blanket halt to exchanges had distinct disadvantages, ranging from a reduction in the exchange of ideas to raising the spectre of Government interference. Boycotts of meetings were not likely to be as productive as participating and expressing human rights concerns, she said. ☐

Rethink for research funding

A LARGE proportion of federal funds for university research should be distributed to institutions on a "formula" basis calculated on proven capability and productivity. Such a "deregulated and decentralised" system for research grants would avoid much of the unnecessary work involved in the current grant-proposal/peer-review process, Professor Rustum Roy, chairman of the science, technology and society programme at Pennsylvania State University, told a session on federal research and development funding. He also suggested a three-year national commission to set national priorities in research and development, with a strong input from the scientific and engineering community.

Professor Roy said existing research and development mechanisms were designed for the "golden age" of science in the 1950s and early 1960s, but were no longer appropriate. The new social setting for R and D included: public recognition of the "ambivalence" of science and technology, rather than seeing either as solely beneficial; widening gap between science and the public; a recognition that there is no simple relationship between support for basic science and a healthy economy; and the fact that the system had not led to maximum innovation in the industrial sector.

The problem lay not so much in getting more money for basic science—"possibly the least important question"—as in designing a more efficient system for the disbursal of funds, where radical changes could produce a major increase in productivity.

A clearly stated rationale for the support of science was also needed. Most important would be contributions to nationally-defined objectives such as defence, health and energy; then would follow science for graduate education, science for state, community and local needs, and finally "science for science's sake". Congressman George E. Brown, a leading member of the House of Representatives Committee on Science and Technology, pleaded for a more sophisticated strategic planning operation for the national scientific effort.

"It is impossible to develop a new rationale for the support of science and better mechanisms for carrying this out without a strong and well-defined central planning authority in the scientific sphere," he said. Some members of Congress had hoped that this role would be played by the President's Office of Science and Technology Policy when it was reestablished in 1976. However, many of the policy and planning tasks envisioned for OSTP had gone to other offices further from the executive centre.

Another need was to develop mutually reinforcing networks of research institutions. "The capabilities of various federal, state and local laboratories must be better linked, both in terms of facilities and people. Only when we have taken such moves can we persuade the public and Congress that critical gaps in research remain and are in need of support." ☐

Assessment of cancer risks comes under attack

EXTRAPOLATING downwards from the effects of exposure to high levels of ionising radiation is an inadequate basis for predicting the dose-response relationship for the incidence of cancer at low levels of exposure, according to Dr Alice Stewart, of the Department of Social Medicine at Birmingham University, England. Such extrapolation would only be valid if cancer was the sole effect of radiation. However there were other indirect effects which would be hidden by the high-dose data, but which would make a linear dose-response relationship untenable, Dr Stewart told a session on epidemiology studies of low-level radiation exposure.

Recent analysis of medical data collected on workers at the US Government's nuclear facilities at Hanford in Washington State, and therefore based solely on low levels of exposure, indicated that a curvilinear model for the dose-response relationship was better than a linear model. The best fit was given by a curve in which the response was proportional to the square root of the dose.

Dr Stewart said medical considerations raised questions about using data based on survivors of the atomic bomb explosions at Hiroshima and Nagasaki as a basis for predicting the effects of low-level exposure to ionising radiation. "Claims that the mortality of A-bomb survivors between 1950 and 1974 from diseases other than cancer is unrelated to ionising radiation gave a false impression. This was due partly to the fact that direct and indirect effects of radiation delivered at high dose-rates had similar consequences, and partly to the ease with which other diseases could prevent cancer induction by radiation—or other carcinogens—from developing into clinical cancer".

Prevention at this stage was usually the result of a non-cancer death coinciding with a period of cancer latency. "Optimal conditions for observing cancer effects of radiation are therefore those which combined low rates of general mortality with small doses of radiation delivered at slow dose rates."

Dr Stewart said that these were the conditions surrounding data collected by Dr Thomas Mancuso, of the University of Pittsburgh, on the health of workers at the Hanford plant, which have recently caused considerable controversy by raising serious doubts about the adequacy of current protection measures

Mr George Kneale, a Birmingham University statistician, who has been helping Dr Stewart to analyse Dr Mancuso's results, told the session that the most recent analysis of the data provided a doubling-dose for the incidence of radiation-linked cancers of between 2 and 150 rads, whereas calculations based on a linear extrapolation from data on A-bomb survivors indicated a doubling-dose of between 150 and 200 rads. "On internal evidence the Hanford survey rejects the possibility that the true risk may be as low as it seems from the A-bomb survivors, but we cannot say precisely what the true risk is, apart from the fact that it appears to be higher at low doses than extrapolation downwards from high doses would indicate."

Doubts about the validity of conclusions of epidemiological surveys based on relatively small sample data were raised by Dr Charles E. Land, of the National Cancer Institute's environmental epidemiology branch. Dr Land warned that an inadequate sample size severely reduced the chances of correctly rejecting a false hypothesis of no dose effect at low levels of exposure. "Failure to reject is not strong evidence for the null hypothesis, so the study results are likely to be inconclusive—a wasted effort", he said.

"We do not have the resources for adequate epidemiological studies of populations exposed to low levels of radiation, and if we should try to do them anyway we would run considerable risk of obtaining misleading results, results that would derive at least some credibility from the vast effort of obtaining them," he said. ☐

Meanwhile, back in Washington . . .

DNA critics appointed to advisory committee

Two active participants in recent debates over the adequacy of guidelines for research using recombinant DNA techniques have been appointed to the committee responsible for advising the director of the National Institutes of Health on a number of important aspects of such research

The two—Dr Richard Goldstein, assistant professor of microbiology and molecular genetics at Harvard Medical School, and Dr Sheldon Krimsky, acting director of the program in urban, social and environmental policy at Tufts University—are among 14 new members appointed to the Department of Health, Education and Welfare's Recombinant DNA Advisory Committee by HEW Secretary Joseph A. Califano.

The appointments follow Mr Califano's announcement last month of a number of changes to existing arrangements for regulating recombinant DNA research. The advisory committee is responsible for giving advice on new types of bacteria for use in such research, on whether certain presently prohibited experiments should be conducted, whether additional categories of research should be exempted from the guidelines, and on possible future changes in the guidelines.

Mr Califano also announced that the size of the advisory committee was to be increased to 25, and that the scope of its membership was to be extended to give greater weight to non-scientific representation. The new members of the committee include a professor of education, a professor of law, a prominent environmentalist and a laboratory technician.

In addition to Dr Goldstein and Dr Krimsky, the new members include: Dr Karim Ahmed, senior staff scientist with the Natural Resources Defense Council; Zelma Cason, chief of cytotechnology in the department of cytology at the University of Mississippi Medical Center; Patricia King, professor of law at Georgetown University Law Center in Washington; Dr Samuel Proctor, professor of education at Rutgers University; and Ray Thornton, retiring member of the US House of Representatives and chairman of the House subcommittee on science, research and technology in the last Congress.

The new scientific and medical members are: Dr David Baltimore, (MIT); Dr Francis Broadbent (University of California, Davis); Dr Richard Novick (New York Public Health Research Institute); Dr David Parkinson, (University of Pittsburgh); Dr Damon Pinon, (University of California); Dr Luther Williams (Purdue University); and Dr Frank Young (University of Rochester).

There is thought to have been considerable controversy over some of the other names of "public interest" representatives suggested for possible membership of the committee, particularly since some scientists involved in the research felt that too large a non-technical component might impede the committee's functioning. ☐

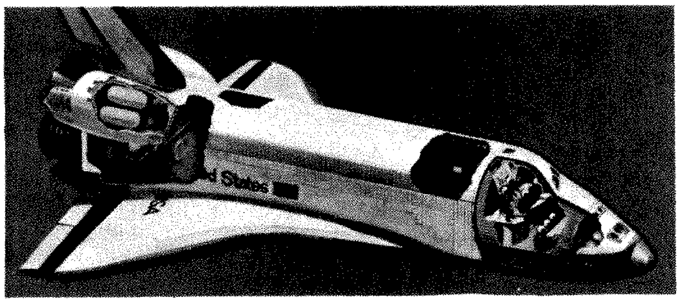
news in brief

Engine failure threatens further delay to space shuttle: An engine failure during testing is threatening further delays to the maiden flight of the US National Aeronautics and Space Administration's space shuttle (artist's impression *below*), currently scheduled for 28 September. The failure occurred during tests two weeks ago near St. Louis, Missouri, when a fire in the high pressure turbo-pump that feeds oxygen into the combustion chamber caused the engine to explode.

Space shuttle's initial flight has already been postponed from March following other problems in the engine development programme, and the delays have added extra costs to the programme. According to NASA, the test engine was heavily damaged in the explosion, and it is expected that it will take three to four weeks to repair the test stand. It is not yet known whether the engine failure will affect the current launching schedule. The agency issued a statement last week saying that an assessment of the impact to the engine test programme and to the first flight schedule was now being made.



Argon isotope ratio on Venus differs from Earth: Data from the latest Soviet Venus probes, Venera-11 and -12, which reached the planet at the end of December "astounded everyone"—according to a report from the flight control centre, broadcast a few hours after the second descent module had landed. The surprising result, it appears, was the unexpectedly high ratio of ^{36}A to ^{40}A in the atmosphere—some 200–300 times higher than the ratio of argon isotopes in the terrestrial atmosphere.

Perhaps the most surprising thing about the result, however, is that this value is a close confirmation of the result obtained by the latest US probe which reached Venus some three weeks before the Soviet modules. If the flight control centre was indeed "astounded", this surely reflects on the rate at which the Soviet team get access to the data from US missions—a point which could well be taken up in any future discussions of peaceful cooperation in space research.

According to the US researchers, the new data suggests a two-stage accretion process of planet forming. Professor Zolotukhin, Deputy Director of the Space Research Institute of the Soviet Academy of Sciences, seems to confirm this view, saying that the Venus argon ratio is "important for the study of the evolution of the planet".

A more popular report from the flight control centre, however, took a somewhat different line. According to commentator Nikolai Zheleznov, the argon value, taken in conjunction with the high surface temperature and dense atmosphere, suggests that the process of chemical evolution of the substances comprising the planet was "lengthened", thereby making the "paths of development" of Earth and Venus "diverge".

UK scientist wins redundancy pay: A cell biologist has won £400 redundancy pay from his former employer, the Imperial Cancer Research Fund. The ICRF has a clause in its contracts of employment for untenured staff which states that they waive their rights to redundancy payment. Redundancy claims therefore are complicated and must be based on technicalities in the law. In this case the contract was for one year. The waiver clause is invalid for contracts of less than two years. The ICRF could have argued that the scientist's employment, consisting of one two-year contract and two one-year contracts, constituted more than two years total employment but decided not to contest the claim. Workers under age 41 are entitled to one week's pay for each year of employment not exceeding £100 per week. Of the ICRF's 128 scientific staff 40% are tenured, 15% on limited-term contracts are eligible for tenure and 45% are employed on non-renewable fellowships.

Sun powered telephones in Jordan: Over 80 solar powered telephones have been installed along Jordan's roads to provide motorists with an emergency telephone service. At the top of each telephone pole is a plate of solar cells which convert sunlight into an electric current that charges a storage battery of 36-hour capacity. The telephone is connected to a UHF transmitter powerful enough to reach the nearest microwave installation. Each telephone is equipped with a series of push buttons marked for the type of emergency service needed. At the push of a button the corresponding signal is relayed to an operator at one of three central exchanges. The system is especially designed for foreign speakers but a receiver is available for voice communication.

Saudi Arabia creates a new science and technology centre: The Kingdom of Saudi Arabia has announced the formation of an independent Saudi National Centre of Science and Technology. The centre will be responsible for support of scientific research and for coordination of existing scientific agencies in accordance with Saudi Arabian Development Plans. The brief of the new centre includes starting special research laboratories appropriate to the research needs of the kingdom, assistance to the private sector for research into increasing industrial and agricultural production, and support for specific research projects including grants to develop local skills for scientific research.

The centre is to seek joint projects with international scientific agencies and to propose a detailed plan "to realise the kingdom's objectives in technological fields". The local scientific community has welcomed the centre as an important part of Saudi Arabian social and economic development.

EEC announces fusion programme for 1979–1983: The total cost of the 1979–83 fusion programme proposed by the European Commission is 921 million European units of account (1 EUA=$1.3). Of this sum 185 million EUA is scheduled for the Joint European Torus (JET) of which 80% will be paid by the commission. The remaining 736 million EUA will be spent over the next five years on the rest of the EEC's fusion programme which includes research on Tokamaks, new plasma heating systems, inertial confinement, tritium technology and materials research.

Already 70% of the contracts have been placed for the fabrication of the machine parts of JET. In February the first stone will be laid for its building in Culham near Oxford. Construction of the machine itself will begin in 1981 and is expected to be finished by 1983 when the first tests can begin. JET is to be built with the participation of all nine community countries plus Sweden and (shortly) Switzerland. After a three-year struggle, the Council of Ministers decided in May 1978 to site the machine in the UK at Culham.

Amorphous silicon: where now?

from S. R. Elliott

ONE of the more extensively studied materials in solid-state research at present, certainly in the field of amorphous semiconductors, is the amorphous silicon–hydrogen alloy system. Upward of 30 laboratories around the world are now working on these materials. The reasons for all this activity are, of course, not hard to discern; they are principally its photovoltaic properties and their possible exploitation in solar energy conversion (see for example *News and Views* **275**, 93; 1978). The attraction lies chiefly in the fact that large area, thin film solar cells could be made relatively cheaply (particularly compared with conventional single crystal devices). However, at present amorphous devices can manage at best only $\simeq 6\%$ conversion efficiency (in contrast to crystalline Si devices that reach $\simeq 16\%$), and it seems that such limitations could be inherent to the process which is currently used to produce these amorphous silicon (a-Si) films.

Spear and his co-workers at the University of Dundee announced in 1975 that by producing a-Si films by means of the decomposition of silane (SiH_4) using an r.f. glow-discharge, doping could easily be achieved by admitting phosphine (PH_3) or diborane (B_2H_6) to the gas flow producing samples which were n-type (the majority current carriers being electrons) or p-type (the majority carriers being holes), respectively. This offered many prospective applications using for example p-n junctions, and was a very significant advance over previous methods of producing a-Si (by vacuum evaporation or sputtering in argon), in which doping was not achieved upon incorporation of the appropriate impurities. The broken (or dangling) bonds introduced in large densities ($\simeq 10^{19}$ cm^{-3}) by these latter preparative techniques give rise to electron states lying deep within the forbidden energy gap between valence and conduction bands, which can trap any excess carriers introduced by dopant atoms. Indeed, these defect states control to a very large extent much of the electronic behaviour of such films.

Studies by Fritzsche (University of Chicago) and Brodsky (at IBM) and others have indicated that a relatively high concentration of hydrogen ($\simeq$ 5–10 at.%, sometimes more) remains within the films prepared by glow-discharge decomposition, a finding not altogether surprising in view of the fact that the decomposition of silane is thermodynamically endothermic. It therefore appears that the presence of hydrogen is in some sense essential to the favourable properties of glow-discharge a-Si. Naively, this can be explained by the notion of hydrogen bonding to the dangling Si bonds, thereby removing their electron states from the energy gap, and thus making doping possible. However, this requires at most $\simeq 0.1$ at.% hydrogen, far less than the amount that is found experimentally. It must be assumed that the balance of the hydrogen is bonded into the random network during growth. The importance of hydrogen in producing films that have favourable photovoltaic properties is underlined by the work of Paul and coworkers at Harvard University, who have produced a-Si:H alloys by sputtering in an atmosphere comprising both argon and hydrogen, which can be doped, and which therefore behave in a manner somewhat similar to those produced by the glow-discharge decomposition of silane.

Despite the promising progress made so far in the field of photovoltaic applications, several problems remain with glow-discharge-produced a-Si. Numbered amongst these are: (1) the variation in properties with the conditions of deposition (for example, the hydrogen content, and hence allied properties, is a sensitive function of substrate temperature, gas pressure, r.f. power); (2) photo-induced changes, such as the metastable decrease in conductivity after optical illumination (Staebler & Wronski *Appl. Phys. Lett.* **31**, 292; 1977); (3) the relative inefficiency of doping, in that only $\simeq 30\%$ of impurity atoms act as donors or acceptors (that is $\simeq 70\%$ bond according to their normal valence and are not forced into tetrahedral environments on substituting for Si atoms) and the Fermi level can only be moved to within $\simeq 0.2$ eV of the conduction or valence band edge; and (4) short minority-carrier lifetimes. In this context, a recent publication by the Harvard group (Paesler *et al. Phys. Rev. Lett.* **41**, 1942; 1978) entitled 'New development in the study of a-Si:H alloys: the story of O', is of interest. This group concentrates on material prepared by sputtering in partial hydrogen atmospheres. They point out that many of the differences in behaviour exhibited by these alloys, compared with those prepared by the glow-discharge decomposition of silane, could be ascribed to the presence of oxygen in the latter; the poorer vacuum and often less pure gases used in the glow-discharge process immediately imply this. To test this hypothesis, samples were produced by sputtering in an argon atmosphere containing both hydrogen and oxygen; the resulting films contained $\simeq 1$ at.% oxygen. They found that the oxygenated films exhibited a much larger photoconductivity and photoluminescence and were relatively insensitive to the partial pressure of hydrogen used, in marked contrast to oxygen-free films; in short, the oxygenated sputtered films more closely resembled glow-discharge samples. It was concluded that in some way the presence of oxygen (along with hydrogen) removes non-radiative recombination channels, perhaps by saturating any dangling bonds present.

Evidence was also presented for the importance of structural defects in the photoluminescence process. This is a much debated subject at present; controversy centres on whether electron states in the energy gap of a-Si:H alloys are introduced by hydrogen atoms attached to Si atoms other than

S. R. Elliott was formerly at the Royal Signals and Radar Establishment, Malvern, and is now at the Cavendish Laboratory, Cambridge.

0028-0836/79/0277—0085$01.00

by simple covalent bonds (Appelbaum *et al. Phys. Rev. Lett.* **39,** 1487; 1977; Singh *et al.Phys. Stat. Sol.* (b) **81,** 637; 1977; Fisch & Licciardello *Phys. Rev. Lett.* **41,** 889; 1978), or whether simple reconstructed Si dangling bonds containing either one or two electrons (and hence positively or negatively charged respectively), give rise to such states, as proposed by the author and Adler (to appear in *Philos. Mag.* and *Phys. Rev. Lett.,* respectively). The short minority carrier lifetime, one contribution to poor device performance, can for example be attributed to such states within the gap, of whatever origin. The Harvard group's paper indicates a possible solution to the problem of the nature of the defects, although it does not resolve the issue.

However, all such considerations may be made redundant with the announcement by Ovshinsky (*Nature* **276,** 482; 1978) that a-Si alloys produced from a mixture of silicon tetrafluoride (SiF_4) and hydrogen, and therefore containing both fluorine and hydrogen, are markedly superior to those produced by the glow-discharge decomposition of silane. Doping efficiencies are larger, photostructural changes are absent, and deposition conditions only weakly affect the properties of these a-Si-F-H alloys, in sharp contrast to the problems that bedevil silane glow-discharge films. Perhaps here lies the road ahead for amorphous silicon alloys. ☐

Ecological interactions in the Southern Ocean

from Robert M. May

THE Southern Ocean sustains a great variety of vertebrate species, including whales, seals, birds and fish.

Very many of these species share a common resource, the shrimp-like krill, as the main component of their diet. The mechanisms whereby these competing species coexist are of interest in illuminating general ecological principles. Viewed in this light, the massive depletion of the populations of large whales constitutes a vast, and sadly ill-documented, ecological experiment.

Whales

As a group, the whales probably originated about 60 million years ago. Their patterns of distribution in the Southern Ocean must have been subject to many changes in the past few hundred thousand years, with the comings and goings of the Ice Ages. The large baleen whales in this area comprise six species and one subspecies—the southern right, humpback, fin, sei, minke, blue, and the subspecies pigmy blue. There is one large toothed whale, the sperm; only adult males enter Antarctic waters. In addition there are nine species of small toothed whales, which include the killer whale *Orcinus orca,* the southern white-sided dolphin, and two species of beaked whales. Little is known about the ecology of these smaller toothed whales.

Laws (*Phil. Trans. Roy. Soc. Lond.* **B279,** 81; 1977 and in *Adaptations Within Antarctic Ecosystems* (ed. Llano), Smithsonian Institution, 1977, hereafter referred to as Laws I and II, respectively) has drawn together much earlier work, to give a fascinating account of the mechanisms of ecological separation among these whale and other species.

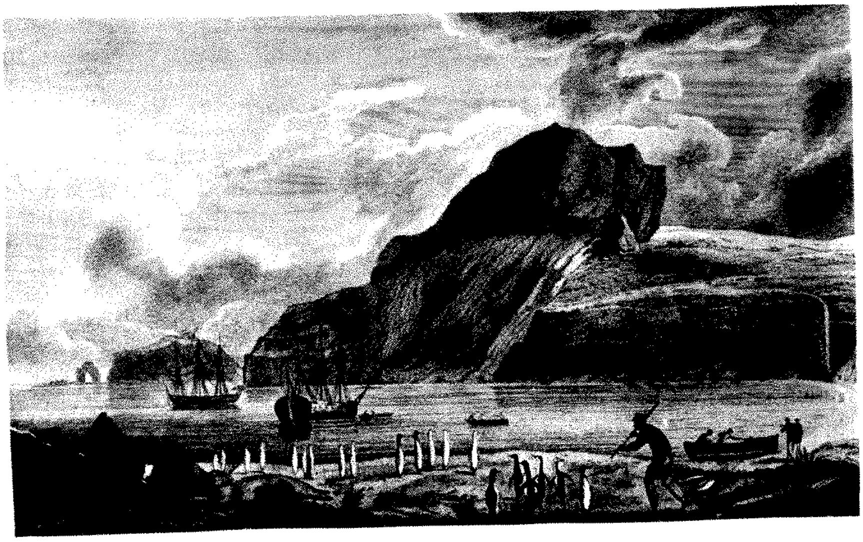
The standing crop of zooplankton, mainly krill, in the Antarctic is at least four times that in the tropics, but it is a highly seasonal resource for whales. In addition to seasonal changes in krill abundance itself, the krill zone is nearly all covered by pack ice in the southern winter; in summer the ice retreats and 80–90% of the krill zone is exposed when the pack ice is at its minimum in March. Most of the baleen whales make long migrations, feeding in summer in the food-rich Antarctic waters, and breeding in winter at low latitudes, where they of necessity fast and rely on energy stored as fat (blubber). A conservative estimate of the weight lost in winter is 20%, which compares with many terrestrial mammals, such as deer. The migrations appear to be staggered, with the different species arriving in the Antarctic at different times in the summer. The blue appears earliest, the fin and humpback next, and then the sei. These waves of migration also reflect the extent to which the different species penetrate into colder waters; the blue appears first and follows the retreating pack ice south, while the other species fill in behind it. Ohsumi *et al.* (*Sci. Rep. Whales Res. Inst.* **22,** 75; 1970) estimate that the highest densities of sei whales are found in the circumpolar zone spanning 40-50°S, fin in 50-60°S, and blue and minke in 60-70°S. The pigmy blue whale seems confined to waters north of 54°S. The southern right whale is probably not migratory and may feed all year in the zone 30-50°S (see Fig. 1).

With the conspicuous exception of the minke, the timing and extent of the migration patterns correlate with the body sizes of the species, and with their percentage proportions of meat and blubber: blue, 39% meat and 27% blubber; fin, 46% and 24%; sei, 59% and 17%; minke, 62% meat and 15% blubber. Although the minke penetrates far south, its low proportion of blubber and small size suggest it is a more continuous feeder than the larger and more migratory species. It also has a higher population turnover, with a 1-year reproductive cycle in contrast to the other whales' 2-year cycle. Within this set of species, we may view the minke as the r-selected opportunist, superimposed on the smooth pattern of spatial and temporal segregation manifested by the other baleen whales.

The baleen whales are the top pre-

Robert M. May is Class of 1877 Professor of Zoology at Princeton University.

A view of Christmas Harbour in Kerguelen Land. From a contemporary account of Cook's third voyage.



dators in a very short food chain, filter-feeding on planktonic crustacea. The rough geographical zones occupied by krill, the major species of these crustacea, are also indicated in Fig. 1. The baleen plates of the various whales are adapted to the size of the food taken: the right whale, which feeds primarily on small copepods, has very fine long baleen and the mouth is enlarged to accommodate them; the filtration by the plates of the sei, minke, humpback, fin and blue is increasingly coarse. Feeding behaviour also varies. The fast-swimming blue, fin, minke and humpback whales swallow in discrete mouthfuls which is more effective with swarming food organisms such as krill, while skimming with the mouth closing at longer intervals (as done by right whales) works better against dispersed organisms such as copepods. The sei uses a combination of the two.

The main sperm whale stocks are found outside Antarctic waters, and females rarely penetrate latitudes beyond 45°S. Solitary males begin to show migratory behaviour as they attain sexual maturity (starting around age 12 years), and their propensity to migrate to Antarctic waters in the summer increases as they get older, levelling off around age 25 years when they may attain the status of harem master in the breeding herds at low latitudes. Sperm whales feed largely on squid species found in temperate and Antarctic waters.

Although not much is known about them, the smaller toothed whales are probably resident in Antarctic seas all the year round.

Rough estimates of the past and present numbers and biomass of large whales in the Antarctic are given in Tables 1 and 2, along with estimates of their food consumption (simplified from Laws I). These numbers are not graven in stone; the many uncertainties in the data are such that no two published tables are identical. A list of the main assumptions and uncertainties is as follows. One-half the total sei whale stock, and one-third of the 'exploitable male' sperm whales are assumed to feed in the Antarctic, south of the Antarctic Convergence. The figure of 10,000 blue whales is higher than the 1978 IWC figures, as is their mean weight of 83 tonnes; Masaki and Yamamura (*Rep. int. Whal. Commn* **28**, 258; 1978) give 4,500 at an average weight of 62 tonnes. The minke figures, both past and present, are very uncertain, and estimates range widely (the minke have only recently been exploited, and most information derives from commercial whaling). With the exception of the minke, which is assumed to feed all year in Antarctic seas, the whales are taken to spend 120 days feeding in the Antarctic.

Table 1 Initial whale stocks

Species	Population (thousands)	Weight (thousand tonnes)	Biomass (million tonnes)	Food consumed (million tonnes) Krill	Squid	Fish
Baleen whales						
Blue	200	88	17.6	72	0.74	1.5
Fin	400	50	20.0	81	0.84	1.7
Humpback	100	27	2.7	11	1.11	0.2
Sei	75	19	1.4	6	0.06	0.1
Minke	200	7	1.4	20	0.20	0.4
Baleen total	975	—	43.1	190	2.00	3.9
Sperm whale	85	30	2.6	—	10.2	0.5

Table 2 Present whale stocks

Species	Population (thousands)	Weight (thousand tonnes)	Biomass (million tonnes)	Food consumed (million tonnes) Krill	Squid	Fish
Baleen whales						
Blue	10	83	0.83	3.4	0.04	0.07
Fin	84	48	4.03	16.4	0.17	0.34
Humpback	3	27	0.08	0.3	0.00	0.00
Sei	41	18	0.71	2.9	0.03	0.06
Minke	200	7	1.40	19.8	0.20	0.41
Baleen total	338	—	7.05	42.8	0.44	0.88
Sperm whale	43	27	1.16	—	4.63	0.24

Some of the consequences of the great differences between initial and present stocks are pursued below. A gross summary is that the pristine biomass density of baleen whales over the area of the krill zone was about $2.6\ \mathrm{g\ m^{-2}}$, while it is now $0.4\ \mathrm{g\ m^{-2}}$

Seals

The seal families probably originated about 30 million years ago in the northern hemisphere, and crossed the tropics along the west coast of South America during a cold period, to radiate into the Southern Ocean. There are now five species of 'true' seals south of the Antarctic Convergence—Weddell, leopard, crabeater, Ross and elephant—along with the Antarctic fur seal. Although there are fewer species in the Antarctic than in the Arctic (probably because the wide deep ocean has no geographical barriers to help speciation), the populations of individual species and the body sizes of their constituent members are larger (probably because food is more abundant). Of the roughly 30 million seals in the world, approximately half live in the Antarctic, where they constitute about 80% of the global biomass of seals.

The species achieve ecological segregation through a mixture of different habitats and different diets. The geographical aspect is set out schematically in Fig. 1, and the food preferences summarised in Table 3. The elephant and Ross seals are both deep-diving squid and fish eaters, but their breeding and feeding distributions have no overlap; the elephant seal breeds on land and is distributed about the Antarctic Convergence, while the Ross seal breeds on ice and is found near heavy pack ice. The fur and crabeater seals are primarily krill eaters; its name notwithstanding, the crabeater has dentition specialised to act as a krill-sieve, producing "perhaps the most complicated arrangement of cusps found in any living mammal" (Laws II). The fur seal breeds on land, and is restricted to the area between the pack ice edge and the Antarctic Convergence, while the crabeater breeds on ice and is restricted to the fringes of the pack ice belt. The leopard seal has a more varied diet (krill, fish, and seasonally penguins) and a wider range than the other seals, but it is primarily found at the fringes of the pack ice zone. The Weddell seal has adapted to fill a specialised niche—the inshore fast ice zone—where it winters under the ice, keeping breathing holes open with its teeth. It eats mainly fish.

The mating systems and patterns of sexual dimorphism correlate strongly with the ecology of the Antarctic seals (Stirling *Rapp. P.-v Renn. Cons. int. Explor. Mer.* **169**, 205; 1975). The polygynous Weddell has a social system intermediate between the highly polygynous and strongly dimorphic elephant and fur seals that breed on land, and the monogamous crabeater and other species that breed on shifting pack ice.

From Tables 1-3 it can be seen that the total biomass of Antarctic seals is less than 10% of the original biomass of large Antarctic whales, and less than half their present biomass. But the seals are present in Antarctic waters all year, and furthermore their metabolic rates and food consumption are relatively larger, because of their smaller body sizes. The consequent estimates of their total annual consumption of krill is about one-third that of the original stocks of baleen whales, and about 1.5 times that of the present whale stocks; seals have now surpassed whales as the major consumers of krill. Essentially all the krill eaten by seals is by crabeaters (to an excellent approximation all Antarctic seals are crabeater seals), who, by foraging at the margins of the pack ice, have relatively little direct overlap with whales.

Male sperm whales and both sexes of elephant seals eat mainly squid in the Antarctic, and, at present whale densities, they eat roughly equal amounts However, when the sperm whales are at peak abundance a large fraction of the elephant seal population is hauled out on land, fasting while breeding and moulting.

The average biomass density of krill-eating seals in summer is around 0.6 g m^{-2}, in regions where they compete with fish, birds and minke whales. The winter density is probably similar, but spread over a different area. Squid and fish-eating seals reach densities around 0.1 g m^{-2} when concentrated in summer, and around 0.03 g m^{-2} when dispersed in winter.

Birds and fish
Surveying a growing, but still limited, amount of information, Laws (II) concludes "the ecological separation of Antarctic birds appears to be determined by the summer distribution and breeding behaviour as they affect feeding". The segregation in the distribution and feeding ranges of some key species of penguins and other birds are shown in Fig. 1.

One example of the way the species sort themselves out is provided by three species of penguin that breed at Sigmy Island. The Adelie and chinstrap penguins feed mainly on krill, but they take different sized prey, either by active selection or by the Adelie feeding further from the rookery (or penguinery). The less common gentoo penguin feeds primarily on fish taken from the seabed.

Petrels and albatrosses also eat krill, squid and fish. In general, the lower latitude species such as the albatrosses are more dependent on squid and fish than the purely Antarctic species.

It is difficult to quantify the biomass and role in the ecosystem of Antarctic birds. Laws gives a rough estimate of 0.03 g m^{-2} for their biomass density when concentrated in the feeding zone in summer, and no more than 0.004 g m^{-2} when dispersed in winter.

Although the facts are not well established, the fish stocks in the Antarctic are probably much less than those in the Arctic. The main reason is that the Antarctic has a very narrow and relatively deep continental shelf, so that spawning sites for bottom-spawning fish are very limited. Some southern species have overcome this problem by spawning in coastal waters in the Subantarctic or on the continental shelf of Patagonia, and assuming a pelagic life as adults (when they feed on krill). In contrast with the north, where fish are the main vertebrate animals, in the Southern Ocean whales, seals and birds are more important.

Responses to the decrease in whales
By comparing Tables 1 and 2, it can be seen that the difference between the krill consumed annually by the original stocks of whales and that consumed today amounts to around 150 million tonnes.

What are the implications of this 'krill surplus' produced by whaling? General ecological theory suggests that, in the extreme case where there is no competition among whale species, nor between whales and other species, the 'surplus' will indeed appear as more krill. At the opposite extreme of high niche overlap among the vertebrate species, most of this 150 million tonnes of 'slack in the system' will be taken up (with time lags that may be measured in decades), causing shifts in the relative abundances of species. I think the reality is liable to lie between these two extremes.

Table 3 Seals

Species	Population (thousands)	Weight (thousand tonnes)	Biomass (million tonnes)	Food consumed (million tonnes) Krill	Squid	Fish
Elephant	600	0.50	0.30	—	4.5	1.5
Leopard	220	0.27	0.06	0.5	0.1	0.2
Weddell	730	0.25	0.18	—	0.5	2.2
Crabeater	14,800	0.19	2.87	63.2	1.3	2.0
Ross	220	0.17	0.04	0.1	0.6	0.2
Fur	200	0.05	0.01	0.1	0,1	0.1
	16,800	—	3.46	63.9	7.1	6.2

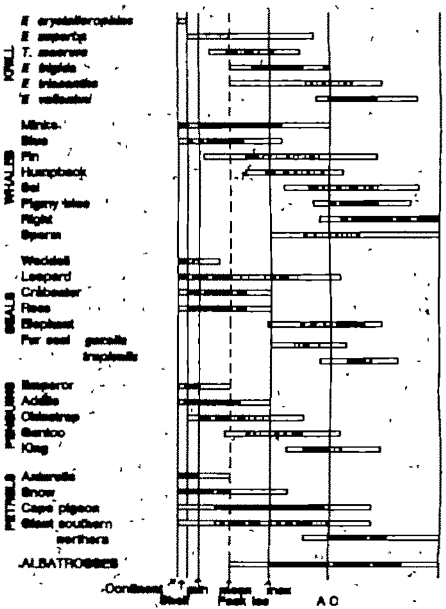


Fig. 1 A comparison of the zones occupied by selected species of krill, marine mammals and birds from the edge of the Antarctic Continent northward. The relative areas of the continental shelf, the minimum, mean and maximum area of pack ice, and of the region south of the Antarctic Convergence (A.C.) are as shown. Each species has a circumpolar distribution, and the average latitudinal range is as shown, with the shading denoting the regime of higher densities. (From Laws II).

Laws (I and II) summarises direct and indirect evidence of population increases in whales, seals and birds that may be attributed to the decline in baleen whale populations.

Increases in the numbers of king penguins seem greater than can be explained simply as recovery from the slaughter of the nineteenth century Population increases have also been shown for chinstrap, Adelie and gentoo penguins. It is noteworthy that the best-documented increases in these populations of krill-eating penguins are in the South Atlantic, where there is the greatest overlap between whales and penguins. In contrast, there is no indication of population increase for Adelie penguins on Ross Island over the past 50 years; interaction with whales is arguably small in the Ross Sea.

Payne (*Phil. Trans. Roy. Soc. Lond.* **B279**, 67; 1977) has established increases in the populations of the southern fur seal that clearly run ahead of simple recovery from over-exploitation. The fastest increase for this krill-feeding animal have taken place in the Scotia Arc, where its distribution overlaps that of baleen whales.

The sei whale has in recent years altered its migration patterns, arriving in the Antarctic earlier and penetrating further south. This could be due to reduced competition from blue, fin and humpback, but it could equally reflect some slow environmental change.

There is clear-cut evidence that pregnancy rates for blue, fin and sei whales have risen, and that the mean ages at sexual maturity have fallen, since intensive whaling was resumed after World War II. For the fin, the age at maturity was steady around 10 years from 1910–30, and has declined to 5–6 years in the most recent age classes. This suggests, again indirectly, increased food abundance. Similar evidence has been adduced for the crabeater seal. In the Antarctic Peninsular, the mean age at sexual maturity for this krill-eater was 4 years until the whaling zone known as the 'Sanctuary' was reopened; since then, the age has fallen to 2.5 years.

The question of the rate at which minke whale stocks are increasing, presumably in response to the effective disappearance of its close competitor the blue (see Fig. 1), is currently the subject of some dispute (IWC, *Rep. int. Whal. Commn.* **28,** 55; 1978).

Laws (II) concludes, "the baleen whales probably remain the most important vertebrate group in their effect on the antarctic ecosystem. Their stocks are likely to stabilise or slowly increase with realistic scientific management, but it is uncertain whether their original abundance will be regained even if commercial whaling ceases". ☐

X-ray absorption spectroscopy

from C. David Garner

ALTHOUGH the existence of fine structure on X-ray absorption edges has been well known for more than 40 years, it is only recently that such data have been shown to provide reliable information concerning the electronic structure and the atomic arrangement about specific atoms in simple or complex materials. This transformation has been made possible by exploitation of the intense continuum of electromagnetic radiation, extending to wavelengths below 1 Å, available from high-energy electron or positron accelerators as a natural consequence of maintaining the charged particles in a circular trajectory. This radiation has a number of unique properties (Rowe & Weaver *Sci. Amer.* **236,** 32; 1977) and is generally known as synchrotron radiation.

The structural information derives from an accurate measurement of the variations in the X-ray absorption coefficient at and above absorption edge(s) of the element(s) of interest (Sayers, Lytle & Stern, *Adv. X-Ray Anal.*, **13,** 248; 1970: Stern *Sci. Amer.* **234,** 96; 1976). Present monochromator design and other limitations effectively restrict studies to the *K*-edges of the elements Ca–Mo and the *L*-edges of elements Ag–U. It is convenient to discuss the potential information contained within the X-ray absorption spectrum as three topics. (1) The actual energy of a particular absorption edge of an element depends on the oxidation state and the nature of the immediate chemical environment of that element. Typically, one unit increase of oxidation state increases the position of the edge by 1–3 eV. (2) The excitation of the core electron into the continuum may be incorporated with transitions from the inner core level to outer bound levels. These internal excitations are usually evident as discontinuities on the primary absorption edge (edge structure) and they can provide information about the electron structure at the absorbing atom in the material of interest. (3) The emitted photoelectron can be considered as a spherical wave radiating from the absorbing atom. This wave will be partially reflected by the electron clouds of the atoms surrounding the absorber; the resultant interference between outgoing and back-reflected waves is manifest as a modulation of the X-ray absorption coefficient at energies greater than that of the absorption edge. This extended fine structure (EXAFS) thus contains information about the number and the type of atoms which surround the absorber and the corresponding interatomic distances. Many of the theoretical problems associated with the interpretation of EXAFS data now seem to have been overcome (Lee & Pendry *Phys. Rev. B* **11,** 2795; 1975: Teo, Lee *et al.*, *J. Amer. Chem. Soc.* **99,** 3854; 1977) and the validity of the structural predictions have been confirmed in a number of studies on materials of a known structure. (Hodgson *et al. J. Amer. Chem. Soc.* **100,** 2748; 1978).

X-ray absorption spectroscopy offers two particular advantages for the study of metal ions in biological systems. First, there is no requirement that the material of interest be crystalline, in principle gases, liquids, glasses and amorphous solids can be investigated. Second, the measurements are specific to the element of interest which may be present at a low concentration, say <1 atom in 10^4. Several investigations of the coordination about a metal ion in a metalloprotein have now been accomplished and the precision of the bond length data, which typically extended to $\sim$3 Å from the primary absorber, can be $\pm$0.02 Å. A unique and valuable insight into the nature of the molybdenum centre of the nitrogenases, has been provided by the measurement and interpretation of EXAFS data for the Mo–Fe protein of *A. vinelandii* and *C. pasteurianum* and the FeMo cofactor of the former (Hodgson *et al. J. Amer. Chem. Soc.* **100,** 3398, 3814; 1978). EXAFS studies for *P. aerogenes* rubredoxin (Shulman *et al. Proc. natn. Acad. Sci. U.S.A.* **72,** 4003; 1975) indicated that all four Fe–S bonds were of equal length, in contrast to the initial prediction of three long and one short Fe–S bond from an X-ray crystallographic structure determination. Subsequent revision of the latter led to a concordance between the two approaches. A similar unanimity exists between the EXAFS and X-ray diffraction studies accomplished for the copper centre of the 'blue' proteins (Hodgson *et al. Proc. natn. Acad. Sci. U.S.A.* **75,** 4069; 1978; Freeman *et al. Nature,* **272,** 319; 1978).

However, the EXAFS determinations of the Fe–N distances in oxy and deoxyhaemoglobin (Eisenberger *et al. Proc. natn. Acad. Sci. U.S.A.* **73,** 491; 1976) have indicated that the iron atom moves much less than the 0.7 Å away from the haem plane suggested from the Hoard–Perutz model. It is thus suggested that the cooperativity between the haem centres does not originate from a significant displacement of the iron atom upon oxygenation.

The paper by Labhardt and Yuen in this issue of *Nature* (page 154) describes the results of an X-ray absorption spectroscopic study of the iron centre of cytochrome *c*. In contrast to the results of an earlier study (Shulman *et al. Proc. natn. Acad. Sci. U.S.A.* **73,** 1384; 1976), a shift in the iron *K*-edge position and the association edge structure of $\sim$1.5 eV was observed on oxidation. The sense and magnitude of the shift are consistent with a redox process which is localised at the iron centre. Furthermore, the EXAFS details indicate that the lengths of bonds involving the iron atom do not change on oxidation (although there is no indication in this paper that these details are consistent with those expected from the studies of Dickerson *et al. J. biol. Chem.* **248,** 5234; 1973). Therefore, the two principal conclusions from this study are compatible with a view that, as expected from Frank–Condon considerations, electron transfer metallo-

0028–0836/79/0277—0089$01.00

proteins contain centres for which the redox change, although primarily located on the metal centre, does not require nor lead to a change in the geometry of the immediate environment of the metal. The EXAFS results for cytochrome *c* and haemoglobin indicate that the conformational changes in the peptide, which register the change in state of the metal centre, almost certainly do not originate as a result of changes in the iron-ligand bond lengths. Labhardt and Yuen suggest that the conformational transition may be initiated by a change in the amplitude of certain low frequency vibrations. This is possible, although, in contrast to their specifications, it seems more likely that the reduced iron centre would lead to a more flexible structure than its oxidised counterpart. Thus the weaker metal–ligand interactions expected for the reduced centre would be expected to result in vibrational amplitudes, for example, for metal–ligand bending modes which, although corresponding to approximately the same average interatomic distances, would be larger than obtained for the corresponding oxidised system at the same temperature.

A real assessment of the contribution of X-ray absorption spectroscopy must await a wider and more detailed series of studies than accomplished thus far. Certain of the present limitations which restrict the range of systems which may be studied and potential interpretive ambiguities will undoubtably be reduced in the near future. However, there seems to be no prospect of obtaining angular as well as radial structural data. Nevertheless, there is no doubt that the validity of this technique is well established and that it offers unique opportunities for the detailed investigations in a wide range of systems. The impact on inorganic biochemistry should be particularly significant. ☐

Coated vesicles

from M. Geisow

GLUTS or shortages of the membranes which enclose cells and their constituent organelles arise under some circumstances. For example, during endocytosis, the plasma membrane of cells is progressively depleted as the cytoplasm becomes filled with endocytotic vesicles. Conversely, following the stimulated release of cell products, excess membrane accumulates at the cell surface at the expense of intracellular pools. In both cases a recovery system is necessary. Reversion to a resting state is achieved in many exocytotic systems by the interiorisation of excess plasma membrane. Vesicles return through the cytoplasm either to subcellular membranes or to lysosomes where they are degraded. Whilst little is known about the nature and composition of such vesicles, recent progress has been made with one class of vesicles with a curious polyhedral 'exoskeleton' which encloses their membranes. This structure has given them the name 'coated vesicles'.

Coated vesicles have been recognised for many years. They were first observed in association with embryonic nutrition, where invaginations of the oocyte membranes were seen to take up food from the external environment into vesicles with a 'bristle coat'. Subsequently many workers have noted this feature in both endocytotic and exocytotic profiles. Palade and his colleagues reported coated vesicles in the Golgi region of secreting cells. Franke *et al.* (*J. Cell Biol.* **69**, 173; 1976) identified an exported product of mammary gland (casein) in coated secretory vesicles.

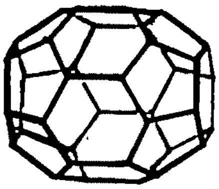

Fig. 1 One structure assigned by Crowther *et al.* to vesicle coats.

Later studies have suggested that the coated vesicle might represent a device for recycling cell membrane. In frog neuromuscular junction Heuser and Reese (*J. Cell Biol.* **57**, 315; 1978) described the sequential fusion of synaptic vesicles with junctional membrane followed by the pinocytosis of presynaptic membrane as coated pits which became coated vesicles. The earlier work of Holtzman *et al.* (*Science* **173**, 733; 1971) with lobster neuromuscular junctions was supported by these findings, although the latter article reported few coated vesicles.

Barbara Pearse has devised a procedure for isolating coated vesicles from various tissues (*J. molec. Biol.* **97**, 93; 1975). Their lattice-like coats are composed predominantly of one type of 180,000 molecular weight polypeptide which she has called clathrin. Several analyses of the coat morphology have been made (for example Kaneski & Kadoki *J. Cell Biol.* **42**, 202; 1969). This and more recent studies (Crowther *et al. J. molec. Biol.* **103**, 785; 1976; Woods *et al. J. Cell Sci.* **30**, 87; 1978) indicate that the clathrin lattice is formed from trimeric associations of clathrin to give hexagonal and pentagonal units (Fig. 1). Alteration in the number of hexagonal units allows the size of the enclosed vesicles to vary without distortion of the lattice.

Peptide maps of clathrin prepared from different species indicate that the protein is strongly conserved (Pearse *Proc. natn. Acad. Sci. U.S.A.* **73**, 1255; 1976). There are also close similarities in the more minor components of coated vesicles isolated from different tissues (Pearse *J. molec. Biol.* **126**, 803, 1978). Pearse suggests that some of these might have a structural role, perhaps relating to the vertices of the polyhedral coat. However, the number of polypeptides obtained from the isolated coated vesicles is small, which is surprising in view of the ultrastructural evidence that they participate in endocytotic and exocytotic transport. Both Pearse and also Blitz *et al.* (*J Cell Biol* **75**, 135; 1977) report polypeptides of 100,000 and 55,000 molecular weight. The latter workers consider that these molecules resemble the major constituents of sarcoplasmic reticulum. They therefore infer that the molecules belong to the transported vesicle rather than to its polyhedral coat. The larger polypeptide in particular appears to be a calcium-transporting ATPase and cross reacts with antisera to the authentic sarcoplasmic reticulum enzyme. It is notable that intracellular and pericellular membrane pools for which the coated vesicle may act as a go-between, contain substantial amounts of calcium-stimulated ATPase (for example, Golgi membranes: Hodson *J Cell Biol.* **30**, 117; 1978), endoplasmic reticulum: Macdonald *et al J. biol Chem.* **253**, 3504; 1978) More work is needed, however, to establish firmly the nature of the components in coated vesicles.

Other intrinsic membrane proteins may be carried by the enclosed vesicle. For example, Gorden *et al* (*Proc natn. Acad Sci. U.S.A.* **75**, 5025; 1978) in a study of the binding of ^{125}I-epidermal growth factor (EGF) to human fibroblasts found that one-third of the specifically bound label rapidly became associated with bristle-coated areas of the plasma membrane (representing less than 2% of the total cell surface) Label and membrane were pinocytosed to form a coated vesicle. It seems plausible that the EGF receptor was also lost in this way, as prolonged stimulation depleted the surface receptors.

Many questions remain unanswered about coated vesicles in particular and

M. Geisow is a member of staff at the National Institute for Medical Research, London.

membrane transport in general. Understanding the control of the assembly, disassembly and destination of coated vesicles now provides an experimental challenge—but why is the cage structure necessary at all? One suggestion has been made that the clathrin physically pinches off a membrane vesicle and at the same time controls the size of the final structure. Another suggestion might be made here. It is widely held that cellular membranes retain their identity with respect to membrane components, even when extensive membrane transport occurs. Is it possible that the closely-applied clathrin molecules provide a 'filter' for some categories of membrane protein, preventing their equilibration between pericellular and subcellular pools? ☐

Prospects for solar energy

from Elizabeth Michelson

THE construction and monitoring of both highly-insulated experimental solar heated houses and solar installations in conventional housing is becoming quite widespread. At a recent meeting held in London* G. O. G. Löf reported on experimental houses that have been built at Colorado State University to compare different types of solar heating systems. Air-circulating systems, with rock storage, were found to supply much the same amount of energy as flat-plate water collectors but were preferable on grounds of cost, durability and lack of problems of corrosion or damage from leakage. In the UK the Building Research Establishment at Watford is to install identical solar heating systems in 80 existing typical 3-bedroomed houses, in order to give a distribution of total daily hot water use, S. J. Leach reported. The ratio of panel area to total daily hot water use and the hot water delivery temperature are the main parameters determining the system performance (B. J. Brinkworth, University College, Cardiff).

There were many shades of opinion on the economic feasibility of solar domestic heating, largely because it rests on speculation as to fuel costs and the general economic situation in the near future. Leach held that a system could only be regarded as economic if it were so now but Brinkworth pointed out that insufficient work has yet been done on the durability of systems, and that this has to be taken into account if the economic viability is to be determined in any set of circumstances. In general, it was agreed, solar water heating is certainly practicable in the UK.

H. Hörster (Philips, Aachen) concluded from theoretical studies that space heating was uneconomic at present in North European or UK conditions. An average house would cost some £2,500 to convert it to the high standard of insulation (as in the Swedish building regulations) needed before space heating is economically feasible. In the South of France however, solar space heating is a good prospect even in the normal house. Between sixty and seventy per cent of US homes already have air-circulating central heating systems and Löf considered that air collectors for space heating, which are presently less common, will become competitive in the near future.

Solar ponds

A solar pond is a water-filled pond, 1-2 m deep, with a blackened bottom for greater heat absorption and a gradually increasing salt concentration towards the base to eliminate convection, which is the main cause of heat loss (H. Tabor, The Hebrew University, Jerusalem). The hot water remains at the bottom from which it is removed as required. Solar ponds tackle several of the major problems associated with other types of collectors; they can easily cover a large area and act as the store at the same time. In Israel, a solar pond will collect about 20% of the incident radiation and Tabor estimated that 200 km^2 of solar ponds would supply all of Israel's current demand for electricity. However, owing to the low ratio of winter to summer radiation, solar ponds are unsuited to high latitudes.

Solar cells

Solar or photovoltaic cells convert light directly into electricity. Of these, single-crystal silicon cells are so far the only reliable and durable ones and have been used for many years in space and for the generation of small quantities of electricity in remote areas (H. Durand, Commissariat à l'Energie Solaire, Paris). Heterojunction cells, in which the semiconductor is made up of two different materials, have the advantage of requiring a much lower-temperature manufacturing process, but have not yet equalled the efficiency and durability of silicon cells (S. Wagner, Solar Energy Research Institute, Golden, Colorado). Optimism for the extensive use of solar cells in the future is witnessed by the passing of the US Photovoltaic Bill allocating $1·5 billion over the next 10 years, $125 million for the present year (Durand). The corresponding present annual budget for Europe is £2·5 million for France and £2 million for West Germany. However, the attractive prospect of direct electricity has cost as one of its chief drawbacks. At present, 1 kW costs between £20,000 and £25,000; improved technology and mass production could reduce this by a factor of thirty. At the same time, the present efficiency of about 16% should not fall below 10% for the costs of encapsulation and installation to remain covered. The US hopes to add solar-generated electricity to its national grid, which can absorb random inputs of ± 15%, since large storage facilities are not feasible.

Energy from biomass

The two most interesting end-products of the action of microorganisms on organic material are alcohol (ethanol) and methane (R. C. Righelato, University of Reading). The production of ethanol by fermentation is very costly because a dilute aqueous environment is required for the reaction and a large quantity of energy, comparable with the energy content of the ethanol, is required to recover the latter from solution. Improvements can be made by finding a method for recovering the alcohol which is less energy demanding than distillation, or using less water initially. Some yeasts can act in concentrations of up to 20% if only for a short time. Ethanol has been produced as a fuel in Brazil, though it is unlikely to make much contribution in the UK.

Gaseous products such as methane emerge from the solution unaided. The production of methane from sewage is more efficient than fermentation, requires less energy input and processes all the material including the cellulose. Methane production has already shown itself to be very practical and is particularly suited to small installations on farms.

As solar collectors, plants have some considerable advantages over man-made collectors. They have large surface areas, built-in storage and an enormous diversity, adapted to almost all conditions (N. K. Boardman, CSIRO, Dickson, Australia). However, the average efficiency of conversion of solar energy is only about 1%. The yield can be increased by the use of fertilisers, coppicing and short rotation crops, though the long-term environmental consequences of these are as yet unknown. Crop residues should also be utilised, but some must remain on the soil to inhibit wind and water erosion and supply nutrients. The crop can either be used as a dry fuel (such as timber) or converted to

---

*A discussion meeting on Solar Energy was held on 15–16 November, 1978 at the Royal Society, London.

0028-0836/79/0277—0091$01.00

ethanol, methane or oil with conversion efficiencies of 20–44% for gases and 58% for oil. Boardman estimated that such liquid fuels could contribute 47% of Australia's transport fuel requirements, one-third originating in crop residue and two-thirds in new fuel crops. Similarly good possibilities exist in Brazil and New Zealand. However, biomass is unlikely to make a significant contribution to the energy requirements of small densely populated countries.

The overall impression was one of optimism, based not on the all-embracing potential of any one method, but on the diversity of methods of harnessing solar energy which, given a rational energy consumption, can make some contribution in almost every climate. □

From sea level to heat flow

from Peter J. Smith

When hot material of mantle origin spreads away from an oceanic ridge zone it cools and contracts. Both theory and observation indicate that the seafloor subsidence thereby produced is proportional to the square root of time, from which it follows that a fast-spreading ridge will have a greater volume than a slow-spreading one. It follows from that, in turn, that, assuming the volume of seawater and the radius of the Earth to remain constant, the sea level will rise during a period of fast spreading. So could variations in ridge spreading rate be responsible for some or all of the fluctuations in sea level that have been known now for more than a hundred years? Hays and Pitman (*Nature* **246**, 18; 1973) thought so and thus added to the large number of explanations previously suggested for changing sea level (glaciation, continental volume changes, Earth's radius changes).

Now Turcotte and Burke (*Earth Planet. Sci. Lett.* **41**, 341; 1978) have taken the logic of this model one stage further and, assuming sea level fluctuations indeed to be indicative of changes in ridge volume, have related changes in sea level to changes in ridge heat flow. The sea level data used were obtained indirectly from Hallam (*Nature* **269**, 769; 1977), who estimated the percentage flooding of North America and the Soviet Union over the past 520 million years from palaeogeographic maps, and from Vail *et al.* (*Am. Assoc. Pet. Geol. Mem.* **26**, 83; 1978), who determined relative sea levels directly for the past 600 million years using a combination of seismology and stratigraphy to detect the onlap of coastal deposits in maritime sequences. The two data sets suggested remarkably similar sea level trends, thereby giving some confidence in the apparent changes in water volume, and hence the supposed changes in ridge volume derived from them, taking into account isostatic responses.

Relating ridge volume to ridge heat flow is a more complex operation in the mathematical sense but can be done using thermal boundary layer theory. Expressing the ridge heat flow as a proportion of total world heat flow is rather simpler, however, although the number of assumptions required (for example, that the Earth's heat is entirely due to uranium, thorium and potassium in the Earth) begins to mount alarmingly. Given the number of assumptions involved and the considerable uncertainty in many of the numerical values used, Turcotte and Burke are cautious in interpretation. Nevertheless they feel justified in coming to two tentative general conclusions—first, that the proportion of the Earth's heat dissipation occurring in ridge zones has generally declined slowly over the past 600 million years much in accord with the decline in heat generation over that period, and, second, that there have been times during the Phanerozoic when the proportion of the Earth's head dissipation occurring in ridge zones, at present 28 per cent, has risen as high as 50 per cent.

According to the interlocking model thus far developed, these ridge heat flow 'highs' coincide, of course, with sea level maxima and hence with the times of the most extensive continental flooding—and the latter occurred about 80 and 400–500 million years ago. The 600 million years of observation is far too short to support any suggestion that these figures indicate cyclic behaviour with a periodicity of about 300 million years, although it is interesting to note that 300 million years is about equal to the turnover time of a mantle convection cell. Moreover, if sea level and ridge heat flow maxima are indeed causally related, both would be expected to be related to convective behaviour, for heat flow variations almost certainly are.

And that leads to another thought. High ridge heat flows correspond with ridge volume maxima which coincide with fast ridge spreading. In turn, this must coincide with increases in the amount of mantle material upwelling at ridges which (assuming an Earth of constant radius) must be connected with increases in the rate of lithospheric consumption at subduction zones. As orogenic behaviour is mainly associated with plate consumption, the implication here is that orogenic processes are also episodic, reaching greatest intensity when the sea level is highest. If it be true, as Turcotte and Burke argue, that the widespread destruction of rocks and structures during mountain building obscures much of the evidence of how and when mountains formed, sea level studies may turn out to be useful in determining the precise temporal variations in orogenic activity. □

Peter J. Smith is a Reader in the Department of Earth Sciences at The Open University.

NATURE

A hundred years ago

I HAVE just read in *Nature* (vol. xix, p. 182) an account of a strange electrical phenomenon observed at Teignmouth. In connection with it the following incident may be of some interest:—When in Switzerland, not long since, I made with some friends the ascent of Monte Rosa. The weather was unsettled, and on gaining the summit we saw a thunderstorm advancing in our direction from the Italian valleys, and not wishing to turn ourselves into lightning-conductors we deemed it wise to retire from the summit. We had retreated a very short distance along the *arête* when the storm-clouds swept up upon us; the fine snow fell so thick that we could hardly see one another, and we were all suddenly attracted by a peculiar ticking or fizzing from our hair; when I held up my axe the ticking was most distinctly heard from the top of it. The thunder ceased, and we felt that we were acting as points, through which the ground electricity was flowing off into the cloud; if it had been dark, the bluish light observed at Teignmouth might have been visible.

As at Teignmouth, so on Monte Rosa; it was freezing hard when the phenomenon was observed.

review article

Multiple receptors for dopamine

John W. Kebabian & Donald B. Calne

Experimental Therapeutics Branch, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health, Bethesda, Maryland 20014

Pharmacological and biochemical criteria can be used to separate those dopamine receptors which are linked to the enzyme adenylyl cyclase and those which are not.

BEFORE discussing the existence of multiple receptor mechanisms for dopamine, some general comments about the definition of receptors are appropriate. The concept of a 'receptor' for a substance arises from the ability of tissue both to recognise and respond to minute quantities of a substance in some precise way. Receptors may be defined according to many different criteria, but it is most profitable to identify the endogenous physiological agent which normally interacts with the receptor. The next stage of classification is based on a combination of pharmacology (that is, identification of drugs which selectively mimic or antagonise the physiological agent) with biochemistry, anatomy and physiology. This second level of categorisation is most useful when it generates the least number of subgroups; however, within a given category, further division is possible into a hierarchy of descending levels (for example, nicotinic cholinergic receptors are further subdivided into ganglionic and neuromuscular receptors). There are many precedents for the existence of multiple classes of receptors for a given biological molecule. Thus, acetylcholine interacts with nicotinic and muscarinic receptors, histamine with H_1 and H_2 receptors, and catecholamines with α- and β-adrenergic receptors.

Dopamine receptors can be characterised by various criteria. In earlier discussions, dopaminergic receptors were classified on the basis of physiological[1] or pharmacological and biochemical[2,3] criteria; alternatively a dynamic equilibrium of a single dopamine receptor fluctuating between two states or configurations has been postulated[4]. The demonstration of a dopamine-sensitive adenylyl cyclase not only provided an *in vitro* model to study the properties of a dopamine receptor but also suggested a mechanism for the generation of the physiological response to this amine[5]. However, not all dopamine receptors have properties similar to those of the receptor linked to adenylyl cyclase. Furthermore, in some tissues, a dopamine-stimulated accumulation of cyclic AMP does not seem to be involved in the generation of the physiological response to dopamine.

Dopamine receptors which increase cyclic AMP synthesis

One physiological action of dopamine is to increase the synthesis of cyclic AMP by the stimulation of a specific dopamine-sensitive adenylyl cyclase[6,7] (for review see ref. 8). The dopamine-sensitive adenylyl cyclase is widely distributed, particularly in neural tissue ranging from gastropods[9] and insects[10] to human brain[11]. The demonstration of a dopamine-sensitive adenylyl cyclase in cell-free preparations of caudate nucleus[6] raised the possibility that the postsynaptic dopamine receptor in this region of the brain could regulate the enzyme. This concept provided the impetus for a detailed characterisation of the dopamine receptor associated with the striatal enzyme; the procedures used to define this receptor involved the use of dopamine itself, analogues of dopamine, and synthetic drugs which stimulate or block dopamine receptors.

Although many structural analogues of dopamine have been tested for their effects upon the striatal adenylyl cyclase, no catecholamine is more potent than dopamine itself. The only catechol-containing molecule which is equipotent with dopamine is epinine (*N*-methyldopamine); any other substitutions on the dopamine molecule produce a loss of agonist activity[12-14]. Summaries of these structure-activity studies have been published previously[8,15]. A number of analogues, which possess dopamine-like activity *in vivo*, have also been shown to mimic the ability of dopamine to increase adenylyl cyclase activity. The semirigid dopamine analogue, 6,7 dihydroxy-1,2,3,4-tetrahydronapthalene (A-6, 7-DTN), is equipotent with dopamine as an *in vitro* agonist[12]. Other structural analogues give less consistent results. Apomorphine is 'classically' recognised to mimic the effects of dopamine[16], but when tested on the striatal enzyme system, this molecule is only a partial agonist[6]; it can antagonise dopamine receptors both in cell-free homogenates[6] and in preparations of intact cells[17].

Antagonists have also been used to define the properties of the dopamine receptor which regulates striatal adenylyl cyclase. Classic antagonists of α- and β-adrenergic receptors are relatively ineffective as antagonists of dopamine[6], but antipsychotic drugs are potent, competitive antagonists[6,11,18,19]. Several dopamine antagonists exist as optical or stereoisomers; the stereoisomers of butaclamol and *cis*- and *trans*-flupenthixol are examples. The clinically active compounds (+)butaclamol and *cis*-flupenthixol are potent dopamine antagonists while the clinically and pharmacologically inactive compounds (−)butaclamol and *trans*-flupenthixol are less potent as dopamine antagonists[18,20,21].

The relative imprecision of the experimental measures of *in vivo* dopaminergic function (for example, turning and stereotypic behaviour in rats, neurological or psychiatric changes in man) preclude an exact definition of the role of dopamine-sensitive adenylyl cyclase in the brain; although dopamine and cyclic AMP have been implicated in electrophysiological events in mammalian superior cervical ganglia[22,23] and in a *Helix* ganglion[9]. However, activation of dopamine receptors of isolated cells of the bovine parathyroid is followed by the accumulation of cyclic AMP and the release of parathyroid hormone[17]. This indicates that tissue-specific responses to dopamine can be mediated by the dopamine-sensitive adenylyl cyclase.

Dopamine receptors which do not increase cyclic AMP synthesis

Other physiological responses to dopamine seem not to involve either the stimulation of an adenylyl cyclase or the accumulation of intracellular cyclic AMP. An example is the dopamine-induced inhibition of prolactin release from mammotrophs.

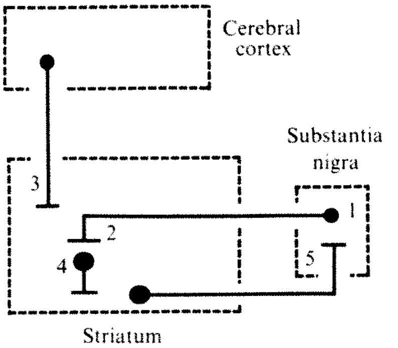

Fig. 1 A schematic representation of the neurones in the nigrostriatal axis which contain dopamine receptors. The dopaminergic neurones contain autoreceptors which regulate either electrical firing of these cells in the substantia nigra (site 1) or tyrosine hydroxylase activity (site 2) on the terminals. Cortical neurones which project to the striatum possess binding sites for radiolabelled haloperidol which have been identified as dopamine receptors (site 3). Neurones intrinsic to the caudate contain the dopamine-sensitive adenylyl cyclase activity (site 4). Finally, terminals of striatal neurones which project to the nigra also contain a dopamine-sensitive adenylyl cyclase (site 5). The dopamine receptors at sites 1–3 have not been associated with adenylyl cyclase activity; only the receptors at sites 4 and 5 regulate this enzyme activity (for references see text).

The synthesis and release of prolactin are under a predominantly inhibitory hypothalamic influence: dopamine in the median eminence functions as an endogenous hypothalamic factor which inhibits prolactin release (for comprehensive reviews see refs 24, 25). The anatomical, physiological, pharmacological and biochemical evidence that demonstrates the presence of receptors for dopamine on the mammotrophs includes the following evidence: (1) Catecholamines, including dopamine, can inhibit the release of prolactin *in vivo* and *in vitro*[26,27]. (2) Dopaminergic agonists, such as apomorphine[28–30] can mimic the inhibitory effect of dopamine. (3) The effects of dopamine can be blocked by several selective dopaminergic antagonists[28,30]. (4) Radiolabelled agonists and antagonists of this receptor bind with high affinity to stereospecific sites that have properties similar to those of the dopamine receptor on the mammotrophs[30–32].

There is no evidence that a dopamine-stimulated accumulation of cyclic AMP can account for the inhibitory effect of dopamine on prolactin release. Cholera toxin, the nonspecific activator of adenylyl cyclase (see ref. 33 for review) has been added to cells of the anterior pituitary or cloned tumour cells derived from the anterior pituitary. Cholera toxin either stimulates[34] or has no effect on the release and synthesis of prolactin (M. Thorner, personal communication); it never decreases prolactin release. Furthermore, dopamine inhibits the adenylyl cyclase from prolactin secreting human pituitary adenomas[35].

A second example of a dopamine receptor which does not stimulate adenylyl cyclase activity is the dopamine receptor (autoreceptor) on the dopaminergic nigro-neostriatal neurones, which are found on presynaptic terminals in the striatum and also on the cell bodies of the same neurones in the substantia nigra[36,37]. Although a dopamine-sensitive adenylyl cyclase has been identified in the substantia nigra[38,39] as well as the striatum[6], the enzyme occurs on cellular elements other than the dopaminergic neurones. Lesions in the nigra induced by 6-hydroxydopamine (which selectively destroys the dopaminergic neurones) do not alter the activity of dopamine-sensitive adenylyl cyclase within either the nigra[39] or the striatum[40]. Conversely, intrastriatal injection of kainic acid, a rigid glutamic acid analogue, destroys neuronal cell bodies in the striatum but spares the dopaminergic nerve terminals; this procedure causes a substantial loss of striatal dopamine-sensitive adenylyl cyclase activity but does not diminish the content of dopamine[41,42]. Thus neither the autoreceptors upon cell bodies in the nigra nor the autoreceptors on the terminals in the striatum appear to be associated with a dopamine-sensitive adenylyl cyclase.

Pharmacological separation of dopamine receptors

Pharmacological evidence indicates the existence of several classes of dopamine receptors. Several antagonists are not equally effective upon different dopamine receptors. For example, the antipsychotic drugs, molindone and sulpiride, and the antiemetic drug, metoclopramide, are dopamine antagonists when tested in the anterior pituitary[43–45] or the brain[47,75]. However, neither metoclopramide nor sulpiride blocks striatal dopamine-sensitive adenylyl cyclase[3,46,75]. Molindone is, at most, a weak antagonist of this enzyme (B. K. Krueger and P. Greengard, personal communication; M. Munemeura and J. W. Kebabian, unpublished observation).

Other compounds are capable of a more limited discrimination between different dopamine receptors. Dopamine itself displays a considerable range of potency at its receptors in different tissues. Nanomolar concentrations of dopamine elicit a response from either the anterior pituitary ($K_a = 35$ nM) or the presynaptic dopaminergic receptors on the sympathetic terminals in the artery of the rabbit ear ($K_a = 37$ nM)[30,48]. The presynaptic autoreceptor on the terminals of the nigro-neostriatal neurones is stimulated by somewhat higher concentrations of dopamine[49]. In contrast, dopamine receptors linked to adenylyl cyclase are stimulated by micromolar concentrations of dopamine. This observation has been made repeatedly in cell-free homogenates of neural tissue derived from species as divergent as the cockroach ($K_a = 2$ μM)[10] and man ($K_a = 6$ μM). Micromolar concentrations of dopamine are also necessary for the accumulation of cyclic AMP in preparations of tissue containing intact cells[5]. Finally, micromolar concentrations of dopamine are required either to stimulate cyclic AMP accumulation or to elicit release of parathyroid hormone in preparations of the bovine parathyroid[17]. Thus, the relative potency of dopamine can be the basis of a categorisation of dopamine receptors.

Apomorphine is another compound with selective activity on different dopamine receptors. In many tissues, apomorphine mimics the effects of dopamine; both dopamine ($K_a = 35$ nM) and apomorphine ($K_a = 3$ nM) are potent activators of the pituitary dopamine receptor[30]. Apomorphine ($K_a = 44$ nM) also mimics the effect of dopamine ($K_a = 37$ nM) on the sympathetic presynaptic receptors of the rabbit ear artery[48]; the potency of apomorphine ($K_a = 300$ nM) and dopamine ($K_a = 320$ nM) on the autoreceptor on the terminals of the nigro-neostriatal neurones are similar[49]. In contrast, in several tissues where dopamine receptors are linked to the enzyme adenylyl cyclase, apomorphine displays activity as a dopamine antagonist. In the striatal dopamine-sensitive adenylyl cyclase system, apomorphine has actions as both an agonist (at low concentrations) and an antagonist (at higher concentrations)[6]; similar observations have been made in kidney vasculature[50]. Apomorphine antagonises the dopamine-stimulated accumulation of cyclic AMP in the bovine parathyroid; the compound has no agonist activity on these cells[17]. Thus, the different pharmacological actions of apomorphine imply the occurrence of more than one type of receptor.

Several ergot derivatives can also distinguish different dopamine receptors. The dopaminergic ergots, such as bromocriptine, lisuride and lergotrile, are extremely potent agonists of the dopamine receptor of the mammotrophs. When tested on isolated cells of the anterior pituitary, bromocriptine has a K_a of 2.9 nM, which is approximately 10-fold more potent than dopamine itself ($K_a = 35$ nM)[30]. Extremely high concentrations of the ergots can cause accumulation of cyclic AMP in some tissues, thereby mimicking the action of dopamine. For example, bromocriptine, like dopamine, causes an accumulation of cyclic AMP in the rabbit retina, but this effect requires a 33,000-fold higher concentration than is needed to inhibit prolactin release[51]. Of greater interest is the ability of such ergots to block the striatal dopamine receptor linked to adenylyl cyclase. This antagonist activity, which is unanticipated in view of the action of such compounds on the anterior pituitary, is seen in both intact and homogenised preparations of striatal tissue[52,53]. When tested in the cell-free striatal homogenate, two dopaminergic ergots, lisuride[54] and lergotrile[55,56] are devoid of agonist activity; both of these compounds are antagonists of the dopamine receptor. These differences in potency and action of the dopaminergic ergots point to differences between the dopamine receptors found in the pituitary and dopamine receptors associated with adenylyl cyclase in the striatum.

Table 1 Criteria for the classification of dopamine receptors

Name*	D-1	D-2
Cyclase linkage	Yes	No
Location of prototype receptor	Bovine parathyroid	Mammotroph of anterior pituitary
Dopamine	Agonist (μmolar potency)	Agonist (nmolar potency)
Apomorphine	Partial agonist or antagonist	Agonist (nmolar potency)
Dopaminergic ergots	Potent antagonist (nmolar potency) Weak agonist (μmolar potency)	Agonist (nmolar potency)
Selective antagonist	None known as yet	Metoclopramide sulpiride
Radiolabelled ligand	*cis*-flupenthixol†	Dihydroergocryptine

* Previously[65], we have designated the two categories of dopamine receptors as 'α-dopaminergic' and 'β-dopaminergic'. This has led to confusion with the α and β adrenoreceptors. The new designations should prevent further confusion.

† Radiolabelled *cis*-flupenthixol can be used as a ligand specific for the dopamine receptor linked to adenylyl cyclase in the rat striatum[64]. Its affinity for the dopamine receptor in the anterior pituitary has not been measured.

Although antipsychotic agents are potent antagonists of dopamine receptors in many tissues, these drugs are of only limited use in discriminating between the different types of dopamine receptors. Various chemically distinct antipsychotic drugs are antagonists of the dopamine receptor on mammotrophs[24]; the potency of some of these compounds has been estimated *in vitro*[30]. In addition, antipsychotic drugs are powerful antagonists of the presynaptic dopamine receptors of the rabbit sympathetic neurones[48] and the autoreceptors on the dopamine-containing nigro-neostriatal neurones[49]. Antipsychotic drugs are also antagonists of the dopamine receptor which is linked to striatal adenylyl cyclase[6,11,18,19].

Among the different classes of antipsychotic compounds, only the butyrophenone series contributes to the identification of distinct types of receptors for dopamine. Butyrophenones, such as haloperidol, are less potent antagonists of the dopamine receptor linked to adenylyl cyclase than would be anticipated from their potency as antipsychotic agents[57] or antagonists of the dopamine receptor in the anterior pituitary[30]. Other antipsychotic compounds do not display such differential activity. For example, the dopamine receptors in the anterior pituitary and those linked to striatal adenylyl cyclase display approximately equivalent affinities for members of the thioxanthine series (for example, *cis*-fluphenthixol), the thiothixene series (for example, *cis*-thiothixene) and (+)butaclamol[6,11,18,19,30].

Radiolabelled ligands

A number of dopaminergic drugs, radiolabelled to high specific activity, havesx used to identify specific neuronal binding sites which may correspond to dopamine receptors. Impressive correlations have been established between the affinity of certain dopaminergic drugs for these specific binding sites and their potency in animal and human tests of central dopaminergic neurotransmission[58]. The physiological and biochemical function of the central dopamine receptors identified by binding studies are only just beginnimv be understood.

The dopamine receptors in the anterior pituitary have been studied with three different radiolabelled ligands, spiroperidol[32], dihydroergocryptine[30] and dopamine[31]. Because the properties of this receptor are well characterised, a correlation between the binding sites and the receptor has been possible[30,31]. There is no direct evidence to suggest that any of the binding sites identified in the striatum with radiolabelled dopamine[58], haloperidol[4,59], spiroperidol[32], apomorphine[60], dihydroergocryptine[61] or ADTN[62] are directly related to the dopamine receptor which regulates adenylyl cyclase activity in this region. Recent studies with kainic acid lesions and ablations of the cerebral cortex provide further evidence to distinguish some of the specific binding sites from the dopamine-sensitive adenylyl cyclase in the striatum[63]. These experiments imply that the striatal dopamine-sensitive adenylyl cyclase is located predominantly on neurones intrinsic to the caudate; in contrast, most of the striatal haloperidol binding sites are located on nerve terminals derived from neurones in the cerebral cortex. Recently, specific binding sites with properties similar to the dopamine receptor regulating striatal adenylyl cyclase have been identified in experiments with radiolabelled *cis*-flupenthixol[64].

A classification of dopamine receptors

It is evident that dopamine receptors can be divided by biochemical or pharmacological criteria. The bovine parathyroid provides an example of a type of dopamine receptor which stimulates the enzyme adenylyl cyclase, whereas the mammotrophs of the anterior pituitary contain dopamine receptors which do not stimulate adenylyl cyclase. We propose that the dopamine receptors in these two tissues are examples of two distinct categories of receptor. The properties of these two types of dopamine receptors, which we designate D-1 and D-2, are summarised in Table 1. This is only the first level of division in the classification of dopamine receptors; it is likely that with further examination, particularly as pharmacological evidence accumulates, subcategories of each type of receptor will be discerned. For example, the autoreceptors on terminals of the nigro-neostriatal neurones can be differentiated from the dopamine receptors in the anterior pituitary[66].

Discussion

As an example of the location of different dopamine receptors within a tissue, it is of interest to examine the striatum, the most extensively studied dopaminergic brain region. We are able to identify dopamine receptors at five sites within the nigro-striatal axis (Fig. 1). The dopamine receptors at three of these sites are not associated with adenylyl cyclase (and therefore would be designated D-2 dopamine receptors in our classification); at two of the sites, the dopamine receptors are linked to adenylyl cyclase (and therefore would be designated D-1 dopamine receptors). In the striatum there are: (1) presynaptic receptors which control tyrosine hydroxylase and are unassociated with an adenylyl cyclase; (2) postsynaptic receptors responding to ergot agonists *in vivo*, also unrelated to an adenylyl cyclase; and (3) postsynaptic receptors closely associated with an adenylyl cyclase. Furthermore, in the substantia nigra there are: (4) presynaptic dopamine receptors (which are associated with adenylyl cyclase); and (5) autoreceptors (unassociated with adenylyl cyclase). From current knowledge, it is not possible to construct a theoretical framework ascribing a function, in terms of motor control, to any of these various dopaminergic mechanisms.

The concept of multiple categories of dopaminergic receptors has important implications for therapeutic medicine. Stimulation of D-1 receptors increases renal blood flow[50]. Dopaminergic agonists are currently used to treat circulatory shock; the pressor agents previously used had the disadvantage of producing renal vasoconstriction and thus decreasing the already compromised vascular perfusion of the kidneys.

Drugs which modify activity at the D-2 receptor have been exploited to treat endocrinological, neurological and psychiatric disorders. Bromocriptine, an agonist for the D-2 receptor, is the most satisfactory drug for stopping lactation in normal post-partum women or for pathological lactation in both women and men[25,67]. Up to 30% of women with secondary amenorrhoea and infertility have hyperprolactinaemia; in the majority of such patients, serum prolactin is reduced by bromocriptine, with consequent restoration of menstruation and fertility[68]. Bromocriptine has also been reported to decrease premenstrual tension in normal women[69] and to improve potency in men with hyperprolactinaemia[68]. In acromegalic subjects dopaminergic agents decrease the pathologically elevated levels of growth hormone; bromocriptine constitutes the first medical form of treatment for acromegaly, reversing the clinical consequences of abnormally high growth hormone concentrations[70]. The neurological features of parkinsonism seem to result from inadequate transmission at certain D-2 receptors. Bromocriptine has a therapeutic effect in the disease[71], and the selective D-2 antagonist, molindone, induces the syndrome[72]. Dopaminergic blocking drugs are the cornerstone of treatment of schizophrenia; most of the agents involved are antagonists of both D-1 and D-2 receptors, but molindone, is an effective agent for treating schizophrenia[72]. In support of D-2 receptor involvement in schizophrenia, it is notable that bromocriptine can induce a florid paranoid psychosis[71].

These examples suffice to indicate that if different categories of receptors mediate the various clinical results of manipulating dopaminergic activity, better treatment should be attainable by developing more specific drugs. At present there are no selective drugs for stimulating or inhibiting D-1 receptors in man, but recent animal studies suggest that such agents will be developed[73,74]. The desire to identify selective dopaminergic agonists and antagonists derives from the therapeutic successes which have been gained in the pursuit of such compounds for adrenoreceptors, histamine receptors, and acetylcholine receptors.

Interparticle collisions, radiation drag and differential precession all tend to disrupt the rings of Uranus. The first two effects lead to radial spreading which would disrupt a free ring in $\lesssim 10^8$ *yr. We propose that the rings are confined in radius by gravitational torques from a series of small satellites that orbit within the ring system. Differential precession tends to destroy the apse alignment of the elliptical* ε *ring. We suggest that apse alignment is maintained by the self-gravity of the ring. The resulting mass of the* ε *ring is* $\sim 5\times10^{18}$ *g. Its radial confinement requires (for example) a pair of satellites of mass* $\sim 10^{19}$ *g, in circular orbits roughly 500 km away on either side of the ring.*

OCCULTATION observations have revealed that Uranus is surrounded by at least nine narrow rings[1-4]. The correct understanding of the origin and evolution of the rings has proved elusive. An early attempt to associate the five original rings with a series of orbital resonances involving known satellites was unsuccessful[5-7]. The subsequent discovery of four additional rings has made this approach less attractive.

The survival of narrow rings poses difficult dynamical problems.

Dynamical problems

Unconstrained rings tend to spread due to particle collisions. The characteristic diffusion time t_D is comparable to the time a particle requires to random walk across the ring[8,9],

$$t_D \sim t_c(\Delta r/\delta r)^2 \sim (\Delta r)^2/\nu \qquad (1)$$

where t_c is the collision time, ν is the kinematic viscosity, Δr is the radial width of the ring and δr is the typical semi-major axis difference of colliding particles. Because the optical depth is at least of order unity, $\Omega t_c \lesssim 1$, where Ω is the orbital angular velocity. The minimum value for δr is the mean particle radius d, so that $\nu \gtrsim d^2\Omega$. With parameters appropriate for Uranus' rings $t_D \lesssim 2\times10^8\ (\mathrm{cm}/d)^2\ (\Delta r/10\ \mathrm{km})^2$ yr.

The Poynting–Robertson effect limits the lifetime of a ring composed of small particles. The torque on an optically thick ring of radius r due to radiation drag is

$$T_{PR} \sim -\frac{L_\odot \Omega r^3 \Delta r}{c^2 a_\delta^2} \qquad (2)$$

where $L_\odot$ is the solar luminosity and a_δ is Uranus' semi-major axis. The orbital decay time for a ring of surface density σ is

$$t_{PR} \sim 4\times10^9(\sigma/\mathrm{g\ cm^{-2}})\ \ \mathrm{yr} \qquad (3)$$

For the two resolved rings (β and ε) the optical depth $\tau \sim 1$ (refs 3, 4). Because $\sigma \sim \rho d\tau$, where the particles are composed of material of density ρ, the decay time is

$$t_{PR} \sim 4\times10^9(\rho/\mathrm{g\ cm^{-3}})(d/\mathrm{cm})\ \ \mathrm{yr} \qquad (4)$$

A ring with a range of particle sizes would spread in the much shorter time

$$t'_{PR} \sim t_{PR}(\Delta r/r) \sim 10^6(\rho/\mathrm{g\ cm^{-3}})(d/\mathrm{cm})(\Delta r/10\ \mathrm{km})\ \ \mathrm{yr} \qquad (5)$$

where $r \sim 5\times10^4$ km.

Combining the relationships for t_D and t'_{PR}, we find that the maximum survival time for a free ring is of order 6×10^6 $(\rho/\mathrm{g\ cm^{-3}})^{2/3}(\Delta r/10\ \mathrm{km})^{4/3}$ yr, and is obtained for a ring composed of particles with masses $\sim(\Delta r/10\ \mathrm{km})$ kg. Therefore, if the rings are not very young, they must be confined. Three lines of evidence point to confinement. First, if the rings are young and unconfined, there should also be older, more diffuse rings visible in the occultation data, and these are not detected. Second, there is very little inter-ring material. A direct map of the rings at $\lambda = 2.2\ \mu$m indicates that the total light reflected by inter-ring material is less than that reflected by the rings, implying a mean $\tau \lesssim 10^{-3}$ between the rings[10]. Third, the ε ring has very sharp edges, which implies that it is not spreading.

Associated satellites

It is plausible that the rings are associated with small, as yet undiscovered, satellites. A satellite can resist tidal disruption at the location of the rings if it is either fairly dense, $\rho_s \gtrsim 2\ \mathrm{g\ cm^{-3}}$, or small, $R_s \lesssim 100\ \mathrm{km}\ \ (p_m/10^7\ \mathrm{dyn\ cm^{-2}})^{1/2}\ \ (\rho_s/\mathrm{g\ cm^{-3}})^{-1/2}$, where p_m is tensile strength ($p_m \sim 10^7$ dyn cm^{-2} for ice and $\sim 10^9$ dyn cm^{-2} for silicates or metals)[11].

For the moment assume that both the satellite orbits and the rings are circular. Consider a satellite separated from the ring by a distance x. The satellite exerts a gravitational torque T_s which tends to repel the ring:

$$T_s \sim \pm f_1 \frac{G^2 m_s^2 r\sigma\Delta r}{\Omega^2 x^4} \qquad (6)$$

where m_s is the satellite mass, Δr is the ring width, σ is assumed to be uniform across the ring, and f_1 is of order unity. The + and − signs apply if the satellite is inside or outside the ring respectively. Equation (6) may be obtained by a crude impulse approximation[12] or by summing the torques from all resonances of the form $\Omega = n\Omega_s/(n\pm1)$ which lie within the ring (ref. 13 and unpublished data).

It is valid for $|\Delta r| \ll |x| \ll r$. Diffuse material between two satellites will be driven into a ring on which the external torque is zero. The external torque deposits angular momentum in the inner part of the ring and removes it from the outer part. Angular momentum is transported outwards by shear stresses due to differential rotation and particle collisions. The ring will narrow until these two processes balance. In equilibrium

$$f_1\frac{G^2 m_s^2 r\sigma\Delta r^2}{\Omega^2 x^5} \sim 2\pi r^3\sigma\nu\left|\frac{d\Omega}{dr}\right| \qquad (7)$$

In equation (7) we assume that both satellites have the same mass. The left hand side is the magnitude of the net external torque on either half of the ring and the right hand side is the

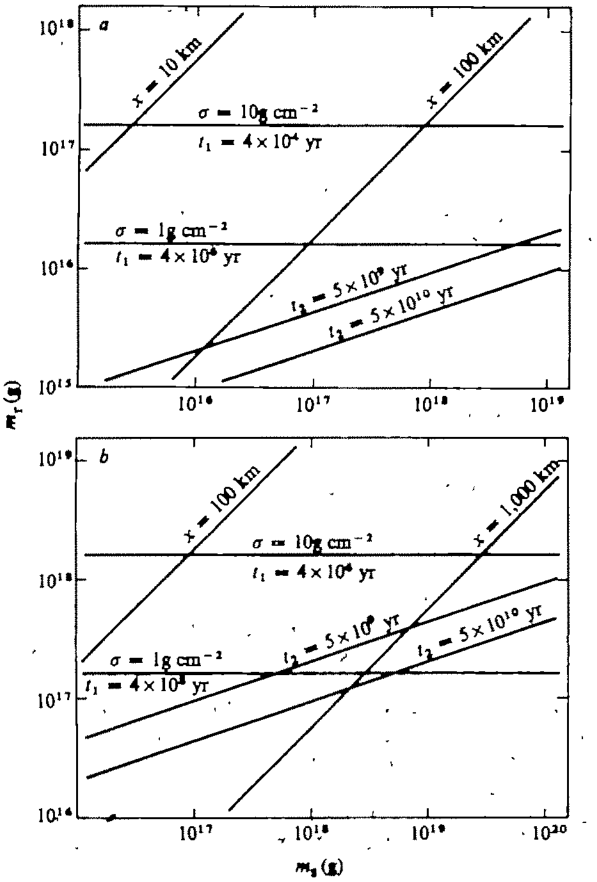

Fig. 1 Lines of constant satellite distance x, surface density σ, formation time t_1 and disruption time t_2 for rings of width: a, 5 km; and b, 50 km. If the satellites are trapped by resonances the value of t_2 is irrelevant. The lines are plotted for $f_1 = f_2 = 1$ and particle density $\rho = 1$ g cm^{-3}. For fixed Δr, m_r and m_s, $x \propto \rho^{2/5}(f_1/f_2)^{1/5}$, $t_1 \propto \rho^2 f_2^{-1}$, $t_2 \propto \rho^2 f_2^{-1}$.

magnitude of the torque associated with the shear stress. As discussed earlier $\nu \gg d^2\,\Omega$.

We now set $\nu \sim f_2\Omega(\sigma/\rho)^2$. For a monolayer of particles with optical depth of order unity, $f_2 \sim 1$. We neglect the Poynting–Robertson torque, which is as important as the torque due to shear stresses for $d \lesssim 10$ cm. We argue below that the average particle size in the ε ring exceeds this limit.

Before viscous stresses become important, the ring narrows at rate $\mathrm{d}(\Delta r)/\mathrm{d}t = \Delta r/t_1$, where

$$t_1 \sim \frac{\Omega^3 r x^5}{f_1 G^2 m_s^2} \tag{8}$$

Using equation (7) it is easy to see that t_1 is just the diffusion time t_D (see equation (1)) for the ring in its equilibrium state. This time is less than the age of the Solar System for a particle size $d \gg 1$ cm.

If the satellites are unconstrained they recede from the ring. The characteristic time in which a satellite doubles its distance from the ring is

$$t_2 \sim (4m_s/m_r)t_1 \tag{9}$$

where m_r is the ring mass,

$$m_r = 2\pi r\sigma\Delta r \tag{10}$$

Sample solutions of equations (7)–(10) are shown in Fig. 1a and b. Not all regions of these diagrams correspond to allowed solutions. Our picture is only valid if several resonances from each satellite lie within the ring. This requires $x \lesssim (r\Delta r)^{1/2} \sim 700\,\mathrm{km}\,(\Delta r/10\,\mathrm{km})^{1/2}$. A similar limit is suggested by the requirement that there is at least one satellite between every two rings, as there are at least nine rings in an interval of 10^4 km. If the satellites are not constrained, we must have $t_2 \lesssim 5\times10^9$ yr. However, the satellites may be trapped in resonances with the known satellites of Uranus. For the corotation resonances discussed previously[5–7] the satellites can be held in resonance if the dimensionless strength of the resonance satisfies

$$\mathcal{R} \gg f_1 \frac{G^2 m_s m_r}{r^2\Omega^4 x^4} \tag{11}$$

Here $\mathcal{R}$ is the amplitude of the resonance term in the disturbing potential in units of $GM_{♅}/a$. In general there are a number of resonances between the rings for which inequality (11) is satisfied[7].

Precessing ellipses

Another remarkable feature is that some of the rings are precessing ellipses. In particular, the inner and outer edges of the ε ring can be fitted by aligned keplerian ellipses with semi-major axes $a \pm \Delta a/2$ and eccentricities $e \pm \Delta e/2$, where $a = 51{,}284$ km, $e = 7.8\times10^{-3}$, $\Delta a = 60$ km and $\Delta e = 7.2\times10^{-4}$. The α, β and 4 rings also seem to be elliptical. The precession is presumably due to the quadrupole moment of Uranus. The observed rates for the α and ε rings together with the formula

$$(\mathrm{d}\tilde{\omega}/\mathrm{d}t)_Q = \frac{3}{2}J_2 n\left(\frac{R_{♅}}{a}\right)^2 \tag{12}$$

yield $J_2 = 3.43\times10^{-3}$ for $R_{♅} = 26{,}200$ km (ref. 4). Naive application of equation (12) predicts that the inner edge of the ring would precess by one revolution relative to the outer edge in 200 yr. Thus the observed alignment of the inner and outer edges must be explained.

The simplest explanation is that the apsides of the ring particles are locked together by the self-gravity of the ring. Consider two particles of mass m moving on aligned elliptical coplanar orbits, with orbital elements ($a \pm \delta a/2$, $e \pm \delta e/2$, where $0 < \delta a/a \ll 1$, $|\delta e|/e \ll 1$, $e \ll 1$. It can be shown that as a result of their mutual gravitational interaction there is a contribution to the precession rate

$$\left(\frac{\mathrm{d}\tilde{\omega}}{\mathrm{d}t}\right)_G = \pm\frac{na}{\pi}\frac{m}{M_{♅}}\left[(\delta a^2 - b^2)^{-1/2}\left(\frac{\delta a}{eb} - \frac{1}{2}\right) - \frac{1}{eb}\right] \tag{13}$$

Here $b = a\delta e + e\delta a$ and we have assumed that the orbits do not cross, so that the quantity inside the square root is positive.

We can determine the mass m_r of the ε ring by dividing it into a large number of subrings, applying equations (12) and (13) to calculate the precession rate of each subring, and requiring that all these rates are the same. A crude estimate of m_r is obtained by making two severe approximations: (1) only two subrings are used; (2), it is assumed that $|b/\delta a| \ll 1$. Then we find

$$\frac{m_r}{M_{♅}} = \frac{21\pi}{2}\frac{e}{\delta e}\left(\frac{\delta a}{a}\right)^3 J_2\left(\frac{R_{♅}}{a}\right)^2 \tag{14}$$

Identifying δa and δe with half the total variation in semi-major axis and eccentricity across the ε ring yields $m_r = 1.1\times10^{19}$ g. A more careful calculation using many subrings and the exact form of equation (13) yields $m_r = 4.8\times10^{18}$ g, corresponding to a mean surface density $\sigma = 25$ g cm^{-2}. We have investigated the precession of rings with a wide variety of surface density profiles and find that m_r is insensitive to the details of the profile. Moreover, the eccentricity is always larger at the outer boundary than at the inner boundary, in accord with observations of the ε ring.

We have considered three other potential mechanisms for maintaining apse alignment in a particle ring. First, the satellites which confine the ring may induce differential precession which cancels that due to the planet's quadrupole moment. However, application of equation (13) shows that the satellite's effect is negligible. Second, interparticle collisions give rise to an effective hydrodynamic pressure which modifies the particle orbits. It is easy to show that smooth pressure gradients are inadequate to overcome the differential precession. Third, a discontinuity analogous to a hydrodynamic shock may form in the ring. A preliminary investigation suggests that, although the induced precession could be significant, it would not maintain rigid precession.

Unanswered questions

Even if the model presented here is correct, there remain many unanswered questions. We have not discussed the origin of the ring material. The approximate equality of the masses of the rings and their confining satellites suggest that the rings may result from the collisional breakup of the satellites. A more speculative possibility is that the rings may reform into satellites.

Our confinement theory is strictly applicable only for circular rings and satellite orbits. Furthermore, we have not investigated the growth and decay of the eccentricities of the rings. It seems plausible that the satellite torques which confine a ring also tend to increase its eccentricity. On the other hand, dissipation due to shear stresses tends to decrease the eccentricity.

If we introduce the surface density deduced for the ε ring into the equations for the confinement of circular rings (see Fig. 1*b*), we find that t_2 is much less than the age of the Solar System. There are several possible explanations. The uncertainty in ρ, f_2 and x means that $t_2 > 5 \times 10^9$ yr cannot be ruled out. Also, the confining satellites may be trapped in resonances. A confinement theory for elliptical rings might yield much larger values of t_2. Finally, the time required for rings to form into satellites may be much less than the age of the Solar System.

The processes which determine the particle size distribution and optical depth in planetary rings are not understood. If there is a substantial population of small particles, the analysis must be modified to include the Poynting–Robertson effect.

The sharp edges of the ε ring pose a challenge to any theory. They suggest that a portion of the constraining torques must be applied very near the ring boundaries.

We thank G. Colombo and P. Nicholson for helpful discussions. This research was supported in part by NSF grant AST 76–24281 and NASA grant NGL-05-002-003.

UV spectrum of supernova remnant reveals carbon depletion in the interstellar medium

The first observation of the far UV, emission line spectrum of a supernova remnant (SNR), namely a filament in the Cygnus Loop, suggests that carbon, initially depleted in the gaseous phase by a factor of 10, is progressively returned to this phase, presumably by destruction of graphite grains in the high temperature, post-shock region.

MODELS for the cooling and recombination of a collisionally ionised gas[1,2] such as is found in SNRs indicate that UV resonance lines of various elements dominate the emission spectrum in the UV–near IR region. In particular carbon, a key element in nucleosynthesis, has no prominent optical lines but emits strong UV lines in different stages of ionisation which can be used to determine accurate abundances.

Previous UV experiments have not looked at SNRs because of the extended nature and faintness of the filaments. We discuss here the first UV spectrum of a SNR obtained with the IUE satellite launched in January 1978 as a combined effort by NASA, ESA and the SRC. The IUE instrument and its performance are described elsewhere[3].

One of the brightest filament of the Cygnus Loop, known as position 1 in a previous study in the optical region[4], was selected for the observation. Filaments such as this are explained as being due to radiative shocks of velocity 90–120 km s^{-1} moving into a medium of density ~6 cm^{-3} (refs 2, 4, 5). This is consistent with the filamentary expansion velocity (~120 km s^{-1}), but is much lower than that inferred from X-ray data. All observations[6-8] favour a plasma temperature of 2–4 × 10^6 K which would imply a shock velocity of about 400 km s^{-1}. The discrepancy has been explained as being due to denser cloudlets embedded in lower density material[10].

It is thought that the UV lines arise from shocks driving into these higher density cloudlets. Although no information can be obtained on the pre-shock density, the UV data can be used to derive a very accurate shock velocity, as described below.

UV spectrum of a filament of the Cygnus Loop

A single, three-hour exposure was obtained in April 1978 in the 1,200–2,000 Å wavelength region using a blind offset procedure. Several emission lines are present including resonance transitions of C, N, O and Si plus the He II 1,640 Å emission. The strength of the geocoronal Lyα prevents any reliable measure of the Lyα emission from the Cygnus Loop. A continuum emission is detected along the full spectrum. The standard data reduction technique[3] was applied. At the time of writing an official absolute calibration for the IUE spectrographs was not available: to derive the relative intensities of the emission lines we have adopted a provisional calibration obtained by

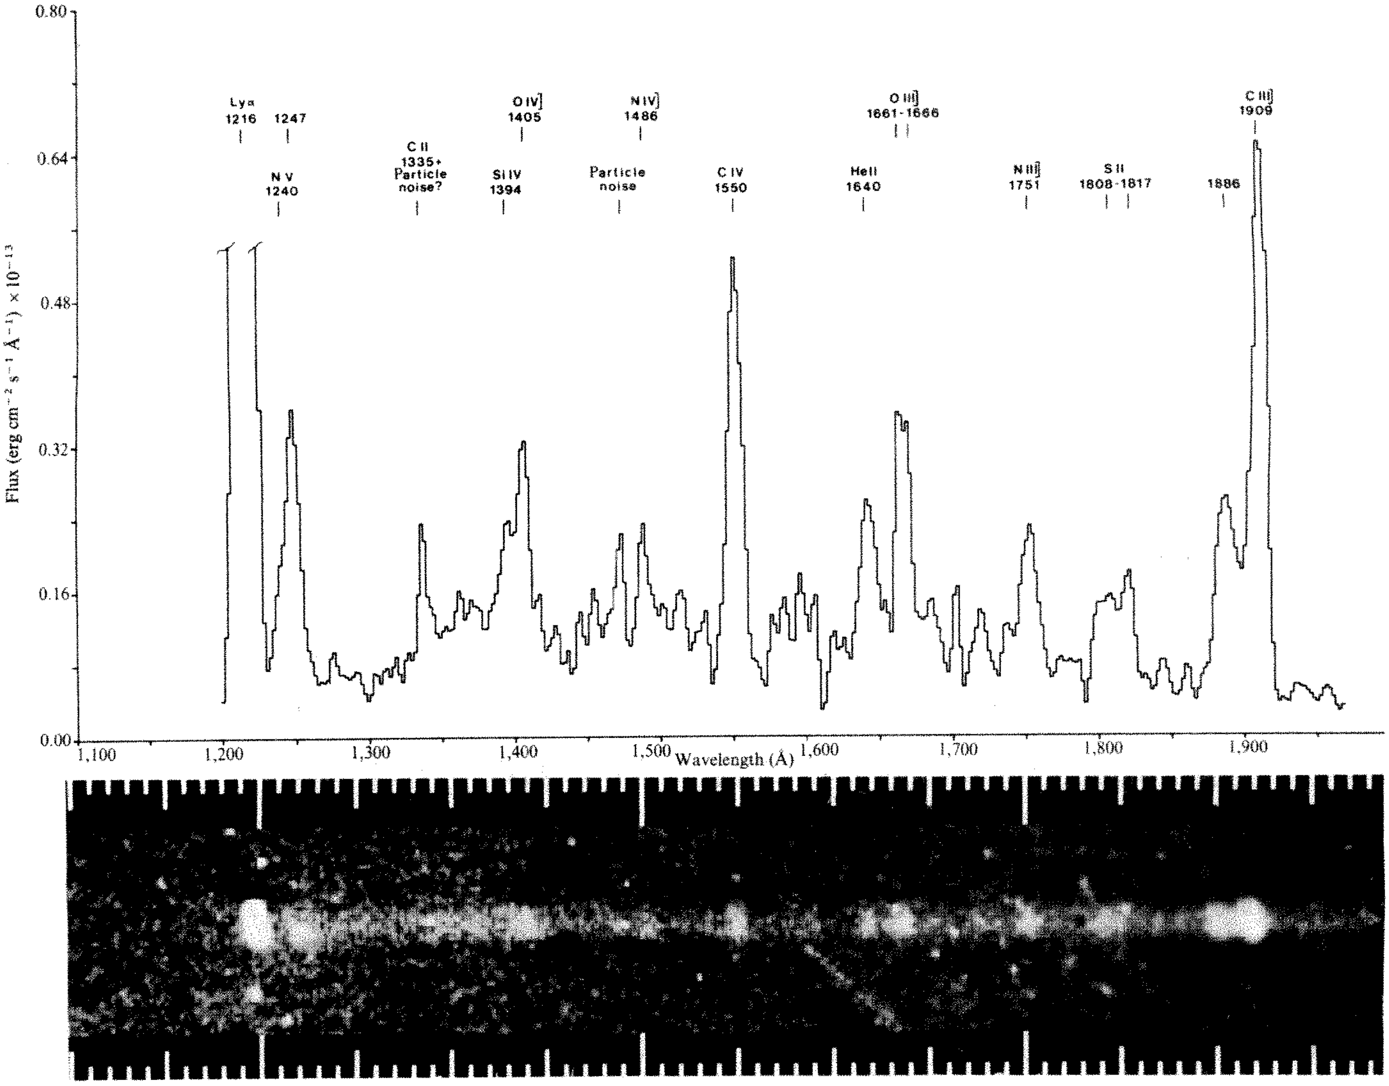

Fig. 1 The UV spectrum of a filament in the Cygnus Loop in the 1,200–2,000 Å range and the resulting intensity plot with the identified emission lines. Several particle events appear as bright points in the three hours exposure.

R. Bohlin from spectra of the star μ Col. As the errors are still uncertain, we will discuss the continuum distribution and the absolute line intensities elsewhere.

Figure 1 shows the reduced spectrum and the resulting intensity plot with the identifications of the emission lines. The spectrum has been smoothed and it is not corrected for interstellar absorption. The feature at 1,393 Å is probably a blend of Si IV 1,394 Å and S IV 1,385 Å, although the silicon should always be about four times stronger than sulphur. Two features at 1,247 Å and 1,886 Å are still unidentified: both seem too far from the plausible lines of Si II at 1,260 Å and Si III at 1,892 Å. Note that a small feature assigned to N V at 1,240 Å is really present even if it has disappeared from the smoothed tracing; its intensity has been measured from the original spectrum. The unidentified feature at 1,247 Å may be a diffuse particle event. Intensities relative to the C III 1,909 Å line are given in Table 1. The estimated error, due to uncertainty in the sensitivity curve and in some steps of the data extraction, is ~30%.

Physical conditions in the filament

The UV data can be used to derive a very accurate shock velocity. The reason for this is evident from consideration of shock models[1,2,5,11]. In the immediate post-shock gas, collisional ionisation increases the state of ionisation of the incoming gas, but, at the same time, cooling processes rapidly reduce the temperature so that the gas never has time to reach collisional ionisation equilibrium, although the maximum state of ionisation will follow the same sort of temperature dependence. Provided that hydrogen and helium are pre-ionised (which occurs[11] for shock velocities >110 km s^{-1}), this maximum state of ionisation is just a function of the post-shock temperature.

As the gas cools rapidly, the temperature at which recombination occurs is effectively dependent only on atomic parameters, and is therefore independent of shock parameters. For species of very low ionisation potential such as C I and S I, the effects of photoionisation by the UV photons generated in the hot plasma become important and this conclusion is no longer valid.

With this simple model a semi-empirical function can be constructed for the ratio of two UV lines produced by ionic species, A^{+n} and $A^{+(n+1)}$, of the same atom. The ionisation balance between the ionic species will be of the form:

$$\frac{N(n+1)}{N(n)} = C_1 T^m \exp\left(-\frac{I_n}{KT}\right) \quad (1)$$

Where I_n is the ionisation potential of ion A^{+n} whose number density is $N(n)$. The power m depends on the recombination coefficient, but should be ~1.3 for a wide range of atoms. The flux produced in UV lines is given by

$$F(n) = C_2 T^{-1/2} \bar{G}(T, Z) \exp(-E_n/KT) N(n) N_e \quad (2)$$

Where E_n is the excitation potential of the transition considered, and $\bar{G}(T, Z)$ is a Gaunt factor of the order unity, a function of both temperature and atomic charge Z (refs 12, 13). From equations (1) and (2) a fairly good approximation for the ratio of the two lines is:

$$\frac{F(n+1)}{F(n)} = C_3 T^m \exp\left(-\frac{I_n + E_{n+1} - E_n}{KT}\right) \qquad (3)$$

In practice, the temperature of the zones producing the two lines will be somewhat different, but this will be ignored in the spirit of the approximation. Hence:

$$\ln\frac{F(n+1)}{F(n)} = \ln C_3 + m \ln T - \frac{I_n + E_{n+1} - E_n}{KT} \qquad (4)$$

At low temperature, the last term on the right-hand side dominates, and T can be given by the post-shock temperature. In terms of shock velocity:

$$\left(\frac{150{,}000\ \mathrm{K}}{T}\right) = \left(\frac{100\ \mathrm{km\ s^{-1}}}{V}\right)^2 \qquad (5)$$

from shock models. Hence, expressing velocities in units of 100 km s^{-1} and ionisation and excitation potentials in electron volts, at low shock velocity, the dimensionless function;

$$\log\frac{F_{n+1}}{F_n} = C_4 - \frac{I_n + E_{n+1} - E_n}{29.75\ \mathrm{eV}}\left(\frac{100\ \mathrm{km\ s^{-1}}}{V}\right)^2 \qquad (6)$$

will correspond to a straight line of slope -1.

On the other hand, at high shock velocity the ratio of the two lines will tend to be constant because they are produced in two zones whose temperatures and thicknesses are in constant ratio. The graph should therefore become a horizontal straight line at high shock velocities.

At intermediate velocities, two effects working in opposite directions have to be taken into account. First, the mean temperature of the zone emitting the $(n+1)$ species line does not increase as rapidly as in equation (5) when this zone becomes thick, but only half as rapidly. This would tend to produce a line of slope -0.5, but for the effect of the second term on the right of equation (4). For $m = 1.3$ this tends to steepen the slope by -0.169, so at intermediate temperature, the curve should have a slope -0.669 or about $-2/3$.

Figure 2 shows the universal curve so obtained for all temperature-sensitive ratios which reach saturation at the highest velocities[2]. Using this in conjunction with the shock models referred to above we derive the shock velocities for the Cygnus Loop observation given in Table 1. The carbon ratios give somewhat lower values than the rest; these are not used for reasons given below. We conclude that, for the region observed, the probable shock velocity is 121 ± 10 km s^{-1}, in excellent agreement with the optical values.

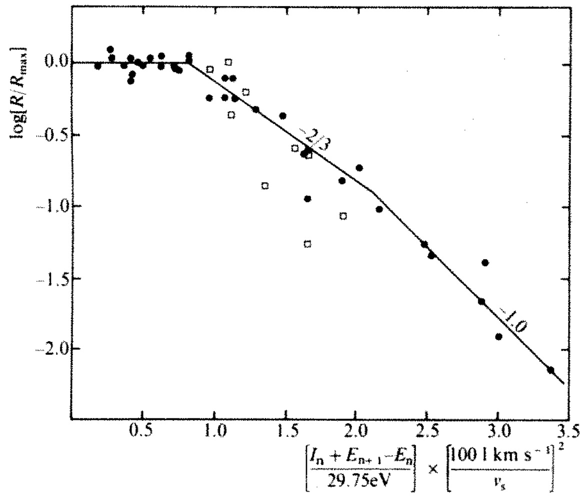

Fig. 2 A plot of theoretical line intensity ratios versus a function of atomic constants and shock velocity. The ratios R are expressed in units of $R_{\max}$, the constant value which is reached at high velocities. I_n is the ionisation potential and E_n the excitation potential for the considered ion and transition respectively. ●, Represent ratios from models which assume full pre-ionisation over the whole velocity range[2], whilst squares are from models with incomplete pre-ionisation.

Table 1 Shock velocities for Cygnus Loop observations

Ratio	Shock velocity (km s^{-1})
O IV λ1406/O III λ1663	117–135
N V λ1240/N III λ1750	126–130
N IV λ1485/N III λ1750	102–118
C IV λ1549/C III λ1909	93–99
C III λ1909/C II λ1335	>88

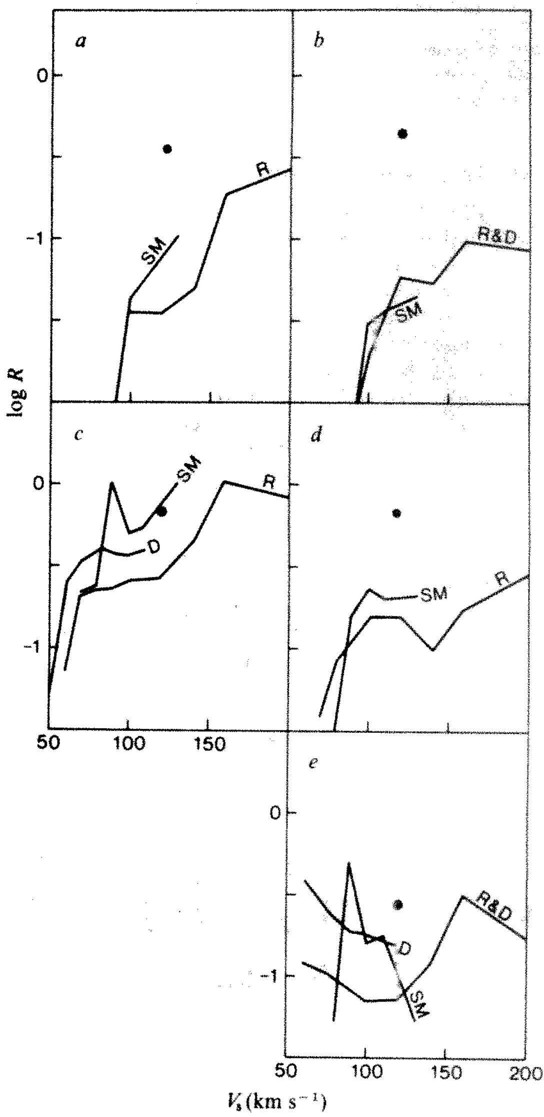

Fig. 3 The lines give the trend of various line intensity ratios as a function of shock velocity for different models (Raymond[2](R), Shull and McKee[11](SM), and Dopita[1](D)) assuming standard abundances. The position of the Cygnus Loop observation (●) suggests an underabundance of all ions of carbon with respect to O, N and Si+S. *a*, O IV/C IV = 1,406/1,549; *b*, N IV/C IV = 1,485/1,549; *c*, O III/C III = 1,663/1,909; *d*, (Si IV + S IV)/C III = (1,394 + 1,385)/1,909; *e*, N III/C III = 1,750/1,909.

Table 2 UV emission line intensities

Line	λ (Å)	Observed	Computed from model X	F	(F+G)	F_d	$(F+G)_d$
C III]	1,909	100	100	100	100	100	100

He II	1,640	36	—	—	36	—	90
C IV	1,549	80	165	252	350	63	88
N IV	1,485	34	13	14*	14	35*	35
O IV]	1,405	27	23	9	30	22	75
Si IV S IV]	1,393	36	2†	16†	22	40†	55
C II	1,335	48	34	42	51	66	81
N V	1,240	31	2	2	14	5	35

X is a carbon-depleted model with $v_s = 100\ \mathrm{km\ s^{-1}}$; F has no depletion and $v_s = 110\ \mathrm{km\ s^{-1}}$; both are from Raymond's work[2].

(F+G) is an average from two undepleted models of Shull and McKee[11]. F_d and $(F+G)_d$ are synthesised models with carbon depleted in ratios.

1.0; 0.4; 0 2 in the logarithm for C IV, C III, and C II respectively.

* Not given in the original computation. Estimated from calculated intensities of the same species with the help of Dopita[1] models.

† S IV not given in Raymond computation. Estimated from Shull and McKee[11] models.

Determination of chemical abundances

As no hydrogen lines are seen, and the spectrum is dominated by the lines of carbon, we derive the abundance of ionic species with respect to the carbon species of closest ionisation potential. This ensures that the error made in mismeasurement of shock velocity is relatively unimportant.

The Cygnus Loop observation, when compared with the results of various shock models, reveals that all other elements (O, N and Si+S) are overabundant with respect to carbon. For the comparison with C III, this effect seems to be $+0.4 \pm 0.2$ in the log, and by comparison with C IV the effect is larger, amounting to $+1 \pm 0.15$ in the log. This effect can either be treated as an underabundance of carbon, or an overabundance of everything else. However, the former is the simplest hypothesis, and we adopt this here. In any event, observations of interstellar dark clouds[14] lead to underabundances of carbon in the gaseous phase of about a factor 10, very similar to the C IV value derived here which is ascribed to graphite grain formation.

In a radiating shock, such graphite grains would pass into the high-temperature zone, and if they are destroyed by the passage through the radiating zone, this would show up as a progressive repletion of carbon in the gaseous phase towards lower temperature. This effect is precisely what is observed here, C IV being 0.6 (in the log) less abundant than C III. At risk of overinterpreting the data, the C II/C III λ1335/λ1909 ratio the data suggests a depletion of 0.2 ± 0.2 for C II.

Introducing depletions of 1.0:0.4:0.2 (C IV:C III:C II) makes all the data consistent. In particular, the C IV/C III λ1549/λ1909 ratio gives a low shock velocity without differential depletion. When this is included, however, the shock velocity derived from this ratio is in the range 110–123 $\mathrm{km\ s^{-1}}$, in full agreement with the other values.

This internal consistency is reflected in full shock model calculations summarised in Table 2. The Raymond model[2] X, used to reproduce the optical spectrum, had a velocity $V_s = 100\ \mathrm{km\ s^{-1}}$ with a depletion of both carbon and silicon. Although this model is a reasonable fit for many lines, it fails for the high excitation ones (such as N IV, O IV) indicating a too low velocity. Higher velocity models without depletion, F and (F+G), fail by predicting too strong C IV and other lines somewhat too weak. Only for the differentially depleted models is there a good fit, with all lines fitting the observations to within a factor of about two, which, bearing in mind the uncertainties in the atomic physics and modelling procedures, is about as good as could possibly be achieved at present.

Conclusion

There is very strong evidence that carbon, initially depleted in the gaseous phase by a factor of ~10, is progressively returned to this phase through the cooling zone, presumably by destruction of graphite grains. The mechanism of this process will be discussed in full in a later paper.

This work was based on observations by the IUE collected at the Villafranca Satellite Tracking Station of the ESA.

Tholins: organic chemistry of interstellar grains and gas

Carl Sagan & B. N. Khare
Laboratory for Planetary Studies, Cornell University, Ithaca, New York 14853

A complex organic solid produced from cosmically abundant molecules helps to explain many properties of the interstellar grains and gas.

FOR the past decade we have been producing[1–4] in our laboratory a variety of complex organic solids from mixtures of the cosmically abundant gases CH_4, C_2H_6, NH_3, H_2O, HCHO, and H_2S. The product, synthesised by ultraviolet (UV) light or spark discharge, is a brown, sometimes sticky residue, which has been called, because of its resistance to conventional analytical chemistry, 'intractable polymer'. However, we have recently suceeded, through sequential and non-sequential pyrolyses followed by gas chromatography–mass spectrometry (GC–MS), in determining something of the composition of this material[3,4]. It is clearly not a polymer—a repetition of the same monomeric unit—and some other term is needed. We have discussed this material as a constituent of the Earth's primitive oceans and therefore as relevant to the origin of life[1]; as a component of red aerosols in the atmospheres of the outer planets and Titan[2,5]; as

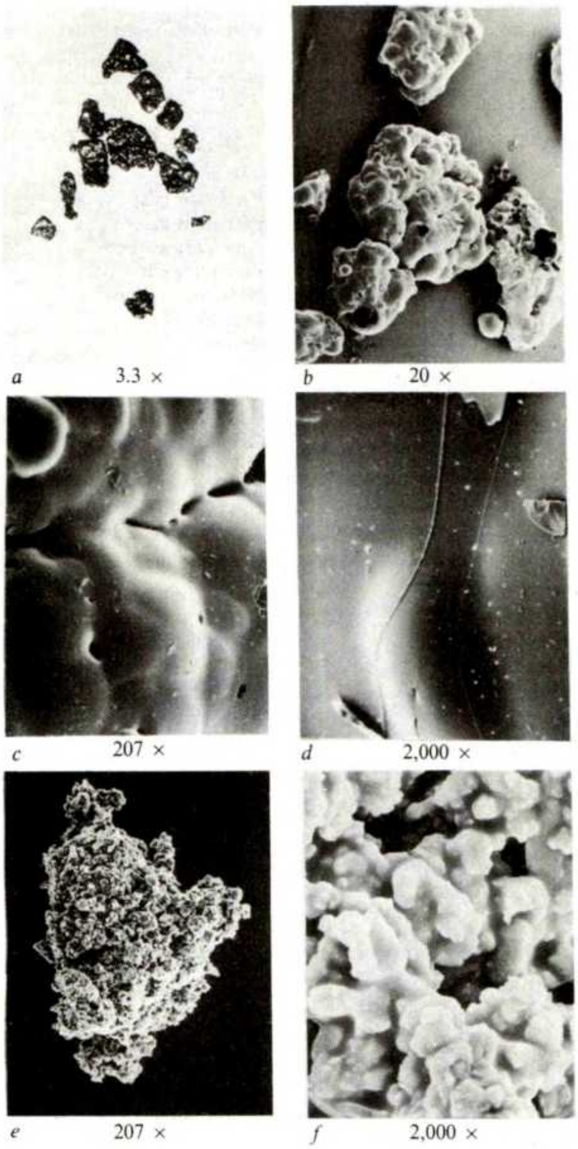

Fig. 1 Light microscopy (*a*) and scanning electron microscopy (*b*–*d*) of spark tholins heated to 920 °C. The smallest particles in (*d*) are the size of interstellar grains. Also shown (*e*–*f*) is the quite different gross structure of UV tholins without elemental S, probably rich in disulphide bridges.

present in comets, carbonaceous chondrites, and pre-planetary solar nebulae[2,5]; and as a major constituent of the interstellar medium, which is the concept discussed here. We propose, as a model-free descriptive term, 'tholins' (gk θὸλος, muddy; but also θολὸς, vault or dome), although we were tempted by the phrase 'star-tar'. The properties of tholins will depend on the energy source used and the initial abundances of precursors, but a general physical and chemical similarity among the various tholins is evident.

UV tholins are produced by near-UV photodissociation of H_2C or HCHO, and chain reactions involving the resulting superthermal H atom. Spark tholins, first made by S. L. Miller[6], are produced by electrical discharges. Both involve the high-temperature dissociation of precursor gases and subsequent low-temperature recombination of radicals. A comparison of the two tholins which we have studied most is presented in Table 1. The 50 or so identified pyrolitic fragments in each tholin extend to molecules as complex as C_3-alkylbenzenes, C_4-alkylthiophenes, C_6-alkyldisulphides, and C_5-alkylthiocyanates in UV tholins; and C_4-alkylbenzenes, C_2-alkylindanes, methylethylpyrazine, glutaronitrile, and $CH_2{=}CH{-}CH{=}CHCH_2CH_2CH_3$ (heptadiene) in spark tholins. (A full list of identified fragments can be found in refs 3 and 4.) There is evidence of amino acid precursors—perhaps polypeptides—in both tholins[4], and a variety of biologically interesting amino acids, including cystine, have been isolated on tholin hydrolysis[1]. The overall tholin structure may be a complex matrix, dotted with aromatic hydrocarbons, pyrroles, pyridines and other rings, and crosslinked with long-chain alkanes, alkenes and polypeptides, somewhat similar to the structure of kerogen or coal. Scanning electron micrographs of tholins are displayed in Fig. 1. The highest molecular weight fragments which have been identified are about 150 daltons, but fragments at 500 to 700 daltons have been observed and still heavier fragments obviously exist. The TGA thermal stability, especially for the spark tholin (Table 1), is impressive; the tholins have experienced a kind of stability natural selection during their synthesis in a UV or high energy proton environment. In their production, the UV tholins received a UV dose exceeding the interstellar near-UV energy density integrated over the lifetime of the Galaxy. The greater complexity of spark over UV tholins at highest magnifications (Fig. 1*d*, 1*f*) may be consistent with the higher stability of the former. We argue here that the tholins are a major constituent of interstellar grains and that their spallation products—similar to the pyrolytic GC–MS fragments—are the primary source of the organic molecules found by microwave line spectroscopy in the interstellar gas.

Table 1 Comparison of typical UV and spark discharge tholins

	UV[3]	Spark[4]
Initial reactants	CH_4, C_2H_6, NH_3, H_2O, H_2S (roughly equimolar)	CH_4, NH_3, H_2O ($\sim 2.5\%$)
Energy source	2,537 Å Hg lamp	High-frequency tesla coils
TGA, 50% thermal dissociation temperature	≃300 °C	≃900 °C
Atomic composition	Apart from S: H, 3.8%; C, 37%; N, 11%; O, 48%	H, 5.0%; C, 47% N, 36%; O, 12%
Principal GC–MS Pyrolytic products	Alkanes, alkenes, aromatic hydrocarbons, alkylthiophenes, alkylmercaptans, alkyldisulphides, isothiocyanates and some nitriles	Alkanes, alkenes, abundant nitriles, aromatic hydrocarbons, alkylbenzenes, indenes, indanes, pyrroles, pyridine, and pyrazines

The conventional composition assigned to interstellar grains—on the basis of their UV and IR spectra, optical frequency extinction, polarisation data and cosmic abundances—is a mixture of silicates, water ice, graphite, carborundum and iron[7–9]. The silicate and ice identifications are probably secure, on cosmic abundance grounds and also, for example, because interstellar features attributed to silicates are also seen in the circumstellar envelopes of oxygen—rich red giant stars. However, it has long been recognised that complex organic molecules provide a possible explanation for several otherwise puzzling properties of the interstellar medium. Sagan[8] argued that the *in situ* formation of the more complex interstellar gas molecules was very difficult to understand, and suggested instead that they are degradation products of the interstellar grains, which he proposed included stable complex organics, ejected from solar nebulae by radiation pressure and stellar winds in the early stages of evolution of stars later than spectral-type F. The fact that the abundances of interstellar organics do not decline steeply with heavy atom number points strongly to an origin as dissociation products of more complex organic species rather than an *in situ* synthesis from interstellar

Table 2 Proposed origin of interstellar molecules (All interstellar molecules composed of C, H, N, and O, known as of mid-1978, are listed, column numerals represent heavy atom number)

Molecule		Relevant laboratory experiment				
		Gas phase spark[30]	Interstellar frost[9]	Spark pyrolysis[4]	UV pyrolysis[3]	Other*
1. Hydrogen	H_2		X	X	X	Precursor gas
Methane	CH_4	X		X	X	Precursor gas
Methylidyne	CH, CH^+	X		X	X	Any hydrocarbon
Ammonia	NH_3	X	X	X	X	Precursor gas
Amino radical	NH_2^+	X		X	X	NH_3, any amine
Water	OH_2	X		X	X	Precursor gas
Hydroxyl	OH	X		X	X	Water

* All molecules cited in this column are identified either in tholin pyrolyzates or in the interstellar medium.

gas. If the presumed dissipation of the preplanetary solar nebula in our Solar System is typical of main sequence stars generally, a significant contribution[10] of organics to the interstellar medium is made, probably enough to coat silicate cores formed, for example, in circumstellar shells (see ref. 40). He suggested that the composition of the interstellar grains might be similar to that in contemporary carbonaceous chrondrites and cometary nuclei. Because interstellar grains might be abundant in preplanetary solar nebulae, and contribute to carbonaceous chondrite chemistry, we note the possibility of multiple recycling of stable organic matter between circumstellar disks and interstellar clouds.

Alternatively, we have shown experimentally[9] that near-UV irradiation at 77 K of stacked layers of HCHO, H_2O, NH_3 and C_2H_6 on a silicate matrix produced, on vapourising the frosts, a variety of simple organic molecules similar to those found by microwave spectroscopy in the interstellar medium, and suggested that organic synthesis also occurs *in situ* on ice-coated grains of silicates or other materials. For both modes of synthesis, Sagan[10] proposed that labile molecules would be preferentially destroyed, and that the steady state molecular population of the grains must, through natural selection, be exceptionally stable complex organics. Because of the Frank–Rabinowitch principle on the stability of multiply cross-linked structures, unbranched aliphatics, say, are not expected to be dominant, while polycyclic aromatics, complexly branched aliphatics and a matrix of mixed rings and aliphatics would be much more likely. Subsequently, Knacke[12] argued that complex organics, including one of our UV tholins, might help explain several unidentified or puzzling interstellar IR absorption or emission features, but was unable to secure an entirely acceptable fit.

Since this early work, very similar ideas seem to have been taken up by Hoyle and Wickramasinghe[13–17], who have paid particular attention to the growing body of data on IR absorption and emission in the interstellar medium. They showed that organic polymers display absorption in the 3 and 8 to 12 μm regions which roughly match the interstellar absorption. In fact, a very wide range of mixtures of complex organic molecules will satisfy such unrestrictive absorptivities, because the 3 μm absorption corresponds to characteristic vibrational transitions of O—H, N—H and, particularly, C—H bonds, while the 8–12 μm region is characteristic of C—C, C—O and C—N functional groups. But they then went on to attempt a more detailed match of organics with interstellar absorption, and claim to have 'identified' the formaldehyde polymer polyoxymethylene and, later, polysaccharides as major constituents of interstellar grains; and have gone still further in postulating sporopollenin, a particular category of polysaccharides found in the cell walls of spores and pollen[18], with typical empirical formulae ranging from $C_{90}H_{115}O_{10}$ to $C_{90}H_{158}O_{44}$, as a reasonable candidate for the composition of interstellar grains.

However, no plausible mechanism for producing such a polysaccharide in the interstellar medium or in circumstellar envelopes has been offered. They are not abundant products in typical experiments on prebiological organic chemistry which involve the irradiation or heating of cosmically abundant substances. They and their pyrolyzates do not appear, to the limit of experimental detectivity, in our analysis of tholins, including experiments in which H_2O is in excess. Polysaccharides are composed only of the atoms H, C and O and therefore do not reflect the high cosmic abundance of N and S, which, as the composition of tholins clearly illustrates, should be major constituents of organic molecules produced from cosmically abundant gases. Moreover, the idea that any particular molecule such as sporopollenin, or even a particular class of organic molecules such as the polysaccharides, should be typical of interstellar grains seems very unlikely; laboratory experience suggests that a very wide range of products should instead be produced under all plausible production scenarios.

There is no such thing as a common IR spectrum characteristic of all galactic sources. Absorption features are well-known in many sources near 3, 10 and 20 μm, but with significant variability from source to source (and in some cases even with time) in the band central wavelengths, depths and half widths. Additional absorption and emission features are known in some sources at 3.3, 6.0, 6.2, 6.8, 7.7, 8.6, 11.3 μm and other wavelengths. The very variability of IR spectra from source to source implies that a variety of molecules are responsible. On cosmic abundance grounds and on the basis of detailed models it seems likely that the 3.1, 9.7, and 18.5 μm features can be explained, perhaps in all cases, by water or ammonia ices and silicates. (Features attributed to ices are very rare in the general interstellar medium and are apparently found only in molecular clouds[19,20]). But even for these features many problems exist. In the source OH 26.5 + 0.6 the 3.1 μm feature is unlikely to be ice because the grain temperatures are too high although it may be due to gas phase (C_2H_2 + HCN) molecular absorption in a cool stellar atmosphere; also the grains show appreciable opacity shortwards of 7 μm where silicates are generally transparent[21]. In compact H II regions and NGC7027 there is a strong emission feature at 3.3 μm which cannot be due to ice, in turn invoked for H II regions to explain the adjacent 3.08 μm feature[22]. In OH231.8 + 4.2≡OH0739 − 14 a deep feature at 3.08 μm still has substantial wings at 2.3 μm, inconsistent with ice; in addition, the relative extinctions at characteristic wavelengths for silicates and ice are inconsistent with known oscillator strengths and cosmic abundances. Likewise the band shapes and depths of features attributed to water ice and silicates in the galactic centre[24] and in the Becklin–Neugebauer Object[13–17,25] in the Orion Nebula are inconsistent with cosmic abundances. The spectra of compact H II regions at 20 to 33 μm are not readily understood in terms of their 10 μm absorptions if silicates are invoked for both[26]. Some of the foregoing difficulties may be resolvable with tholins as additional constituents in the interstellar medium.

Figures 2–4 display the IR spectra of UV and spark tholins, and a few of their extracts and high-temperature phases, compared with a variety of other materials—including a sporopollenin; a thin layer chromatography cellulose matrix, as an example of non-sporopollenin polysaccharides; carbonaceous chondrites[27,28]; and two galactic spectra, one of which is Hoyle's 'best fit' to many galactic IR sources[29]. Spark and UV tholins exhibit substantial family resemblances in the IR; some of the differences are due to S compounds present in the latter and not the former. Heating tholins to high temperatures seems to destroy short wavelength absorption bands and increase continuum absorption. Functional groups are well-known to shift band central wavelengths by several tenths of a μm depending on physical state and adjacent chemistry. Some tholin IR absorptions may be due to collective phenomena (long polymers, for example, having different spectra from monomers); tholin spectra will vary from source to source depending on precursor abundances and energy sources at their origin, heating and irradiation during ejection from circumstellar clouds, and other effects. We believe that mixes of tholins, such as that in Fig. 3, match the galactic spectra at least as well as sporopollenin, and exhibit the additional virtue of having a plausible synthetic mechanism. The fit of four spectral features between 3 and 40 μm will occur by chance with a probability 10^{-8}. We anticipate still better agreement with interstellar spectra for mixes of tholins, ices and silicates.

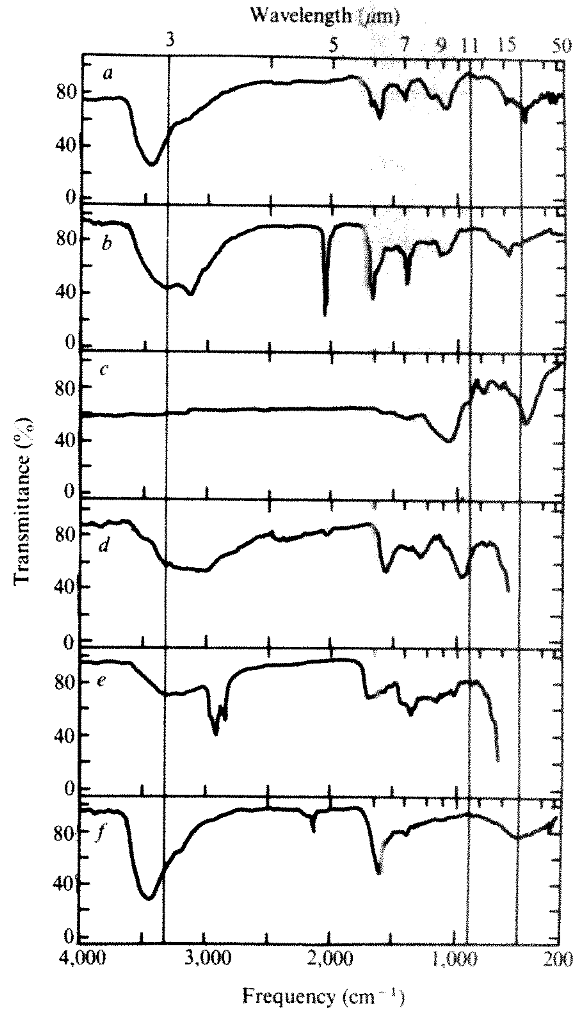

Fig. 2 Comparative IR spectra of *a*, UV tholin; *b*, UV tholin, elemental S removed; *c*, UV tholin, elemental S removed, heated to 450 °C; *d*, methanol extract of UV tholin; *e*, methanol extract of chromatographically separable yellow component of UV tholin; *f*, spark tholin. Vertical lines 3, 11 and 18 μm are for reference.

In NGC7538E, a compact IR source associated with a rich molecular cloud complex, there are unidentified features[30] at 6.0 and 6.8 μm which correlate with the presence of the 3.1 μm feature, but not the 9.7 μm feature. But in our early work on the IR spectra of UV tholins we noted[2] the presence of features at 3.42 and 6.87 μm due to long-chain alkanes, and near 6.0 μm due to alkenes. In fact the presence of these features was a major early clue that long-chain alkanes and alkenes are an important constituent of tholins, a conclusion since confirmed by GC–MS[3,4]. Willner *et al.*[30], who discovered the 6.0 and 6.8 μm features in NGC7538E, hold that a problem with the alkane and alkene identification is that the ratio of gas phase CO to grain CH_2 or CH_3 would have to be as high as 1/3; but such groups are the dominant functional groups in all analysed tholins. If the

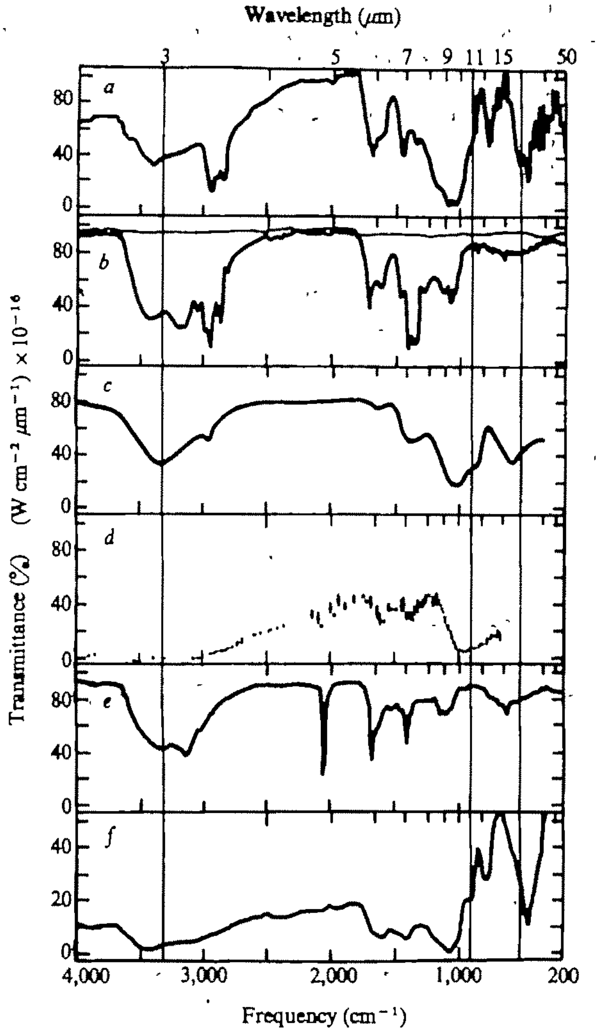

Fig. 3 Comparative IR spectra of *a*, a sporopollenin[13–17] *b*, TLC cellulose; *c*, Hoyle's[29] galactic 'best fit'; *d* NGC 7538E[30]; *e*, UV tholin – S; *f*, linear superposition of (*a*), (*c*) and (*d*) of Fig. 2. The transmission in the 760 to 200 cm^{-1} region in Fig. 2*d* is added at the 100% level.

mantles of interstellar grains are made significantly of tholins, the high methyl and methylene abundances become plausible. There is also a hint in the spectra of NGC7538E of absorption at 4.6 μm, which is characteristic of C≡C and C≡N. Features near 6.2, 7.7, 8.6 and 11.3 μm first found[31] in NGC7027—and since found[30] in many other regions of the Galaxy, as well as in M82—have analogous absorptions in several tholins (Figs 2 and 3). The presence of 8.7 and 11.3 μm features in the young IR source GL437 implies that they are not produced by anomalously abundant elements which might be present in highly evolved objects[32], but rather must be attributed to typical cosmic abundances, consistent with organic molecules.

It is a natural speculation that tholins are present in carbonaceous chondrites, and we[2] and Knacke[12] have compared relevant IR spectra. The agreement is good but not excellent for samples of Murray and Orgueil. We note here (see Fig. 4) a quite good agreement between a particular (hot-water soluble, cold-water insoluble) fraction of the Mokoia carbonaceous chondrite[27,28] and Hoyle's 'best fit' galactic spectrum[29]. However, the chemistry of Orgueil, determined[33] under identical conditions of pyrolytic GC-MS as the tholin analysis, demonstrates a relative dearth of S and N compounds (especially nitriles) in Orgueil. Depolymerisation of the Murchison carbonaceous chondrite reveals a range of organic products very similar to that of S-free tholins[33]. More work is clearly needed on the comparative organic chemistry of carbonaceous chondrites, and, in particular, of the appropriate fraction of Mokoia.

The principal UV interstellar absorption feature is at 2,200 Å, conventionally attributed to graphite, which should be formed and ejected by C-rich red giant stars. However, the graphite identification requires that its structure be well-ordered, which is unlikely in the interstellar radiation environment. Large sheets of polycyclic aromatic hydrocarbons have similar absorption features, but are subject to the same objection. Sakata *et al.*[34] have found a 2,200 Å feature in a hexafluoroisopropanol extract of the Murchison carbonaceous chondrite and attribute its presence to organic molecules with conjugated double bonds of the sort C=C—C=C and C=C—C≡N. But such molecules are abundant in tholins, as in butadiene, heptadiene and butenenitrile. Polysaccharides, on the other hand, exhibit no such feature[35].

The optical region of the interstellar spectrum is noteworthy for the presence of a set of diffuse interstellar lines, the most prominent at 4,428 Å, which have resisted identification for 40 years. The hypothesis that 4,428 Å is the Soret band of porphyrins (tetrapyrroles) is interesting in the light of our identification of pyrrole in spark tholins, but there are serious difficulties with this idea[10]. Douglas[36] has recently argued that the diffuse lines arise from radiationless internal conversion of long-chain C molecules, where the carbon number lies between 5 and 15. Many abundant tholin pyrolysis products satisfy this description. Tholins have a substantial absorption in the blue, responsible for their brown appearance, which is not due to S, and may be caused[2] by conjugated polyenes, H (CH=CH)$_n$ H, where $n \geq 6$. Our pyrolysis fragments[3,4] give good evidence for dienes in both tholins, and longer polyenes seem likely. If tholins are the principal constituents of the interstellar grains, the important conclusion follows that interstellar extinction is not merely due to scattering but must take account of substantial pure absorption as well ($k \sim 10^3$ cm^2 g^{-1} in the violet for UV tholins[2]).

The radii of particles ejected by stellar radiation pressure or stellar winds during the Hayashi or red giant stages of stellar evolution depend on the complex refractive index of the particles, but particles larger than a few μm are unlikely to be ejected. Thus the large tholin particles shown in Fig. 1 would not be ejected, but rather remain in circumstellar space, until degraded by sputtering or other processes into ejection-sized fragments. The smallest particles seen in Fig. 1*d* are, however, <1 μm in diameter and would thus be ejected, but they seem to have the size and at least some of the composition of interstellar grains.

From this general picture, we hypothesise[10] that the organic molecules detected by microwave line spectroscopy are chiefly spallation, spluttering or photodissociation products of tholins in interstellar grains, although UV and cosmic ray-induced positive ion-molecule reactions produce the spheric 1 interstellar organics in dense clouds. Typical lifetimes[40] of icy or dusty grains, unprotected by surrounding interstellar clouds, are 10^8–10^9 years. The interstellar molecules should then resemble the pyrolyzate or MS cracking pattern of the tholins, or the vapourisation products of organics produced by low-temperature UV irradiation of condensates of abundant interstellar gases[11]. In Table 2 this comparison is performed for all identified interstellar molecules composed of H, C, O and N. For simplicity, we have neglected S compounds, but the array of such compounds in appropriate tholins[3] shows that no problems in interpretation are thereby posed. Every identified interstellar molecule either is produced directly in a relevant experiment (75%) or can be produced plausibly from tholin pyrolyzates (25%). Molecules with amino groups are in a special category, since they are degraded to nitriles during pyrolysis; however, the detection of amino acids in our UV tholins, with the very large quantum yield on hydrolysis of $\sim 10^{-4}$, shows[1] that amino groups or their precursors should be present in abundance. There is a tendency (Table 2), perhaps not yet statistically significant, for even C numbers and odd heavy atom numbers to be avoided in high molecular weight interstellar fragments; tholin pyrolyzates do not show such a trend and it will be interesting to see whether microwave lines corresponding to 5, 7, 9 and 11 heavy atoms (such as, methacrylonitrile or toluene) will be found.

The investigation of cometary spectra has now yielded simple nitriles and aldehydes, molecules plausibly derived from cometary tholins formed in the solar nebula[10] and preserved in deep freeze for the intervening 5×10^9 years. The similarities between cometary and interstellar molecules are sufficiently great that searches for a wide range of tholin pyrolyzates and their products seem desirable by remote spectroscopy, but particularly by *in situ* analytic chemistry in a cometary fly-through spacecraft mission. More generally, the tholin fragments identified in the laboratory[3,4] are plausible candidates for future studies of the interstellar medium by UV, visible, IR and microwave spectroscopy. Several molecules (HCN, CH_3CN, HCHO, CH_3CHO, C_2H_5OH) were found[11,37] in such laboratory experiments before their detection in the interstellar medium. The fact that molecules of some considerable complexity are predicted from the tholin argument suggests the need for comprehensive compilations of laboratory spectra of organic molecules, especially in the microwave region. The number of molecules is now so large for a finite microwave spectrum that statistically some molecules identified on the basis of one or two spectral lines may have been identified in error[10].

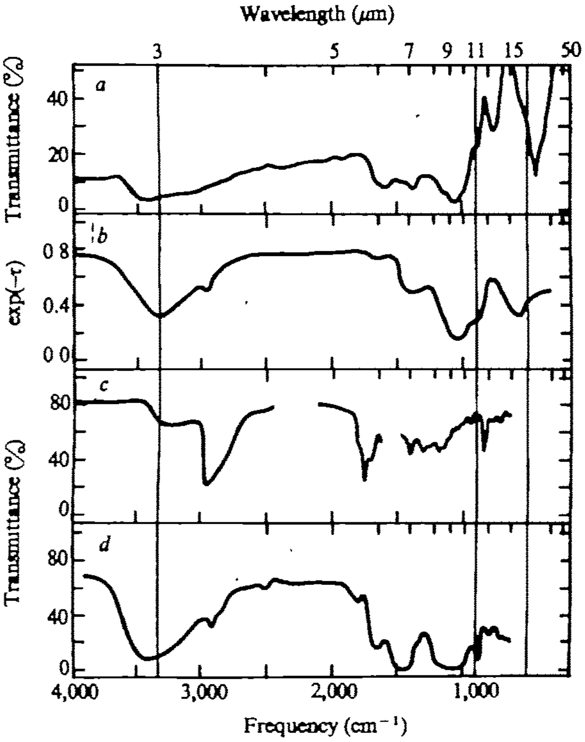

Fig. 4 Comparative IR spectra of *a*, UV tholin mix [Fig. 3 *f*]; *b*, Hoyle's[29] galactic 'best fit', *c*, benzene–methanol extract of the Orgueil carbonaceous chondrite[27,28]; *d*, hot-water soluble, cold-water insoluble extract of the Mokoia carbonaceous chondrite.[27,28]

We believe the connection of this work with the origin and evolution of life on Earth to be indirect, although certainly interesting. The large scale production of complex organics in a preplanetary cloud, and the abundance of simpler organics in so inhospitable an environment as the present interstellar medium, surely imply that prebiological organic chemistry is easy, that much higher quantum yields and synthetic productivities should have applied on the primitive Earth. The presence of cyanoacetylene in the interstellar medium makes its presence, and the copolymerisation of biologically interesting molecules which it induces[34], more likely on the primitive Earth. But the Earth's surface was probably molten in its early history, and organic molecules are unlikely to have survived from the epoch preceding the formation of the Earth, although they should have accumulated thereafter. In any case the synthesis of organics on the primitive Earth seems to have been entirely adequate at least for our present level of understanding of the origin of life[1,10,38]. Surviving exogenous molecules are not needed. Likewise there seems to be no way for indigenous organisms to evolve—the heavy atom collison rate precludes more than about 50 interstellar generations in the age of the Galaxy and the organic reaction rates in cometary nuclei in the Oort cloud should be negligible—much less to arise in the interstellar medium[10] If such organisms did exist[29,39], their pathogenicity on Earth might be an open question, but organisms such as the influenza virus, with a molecular biology entirely typical of indigenous terrestrial organisms, are implausible in the extreme, as extraterrestrial pathogens. There may be a common organic chemistry on countless worlds as in the interstellar medium; but the stochastic nature of the evolutionary process makes it highly improbable that the biochemistry of extraterrestrial organisms will resemble very closely the biochemistry with which we are familiar on Earth.

Synthesis of rabbit β-globin in cultured monkey kidney cells following infection with a SV40 β-globin recombinant genome

Richard C. Mulligan, Bruce H. Howard & Paul Berg

Department of Biochemistry, Stanford University Medical Center, Stanford, California 94305

Rabbit β-globin complementary DNA (cDNA) has been inserted into SV40 DNA in place of the gene coding for the virus' major capsid protein, VP1. The recombinant genome, SVGT5–RaβG, multiplies efficiently in CV1 monkey kidney cell cultures and is transcribed to yield cytoplasmic, polyadenylated hybrid mRNAs containing the β-globin coding sequence. Cells propagating SVGT5–RaβG produce substantial quantities of rabbit β-globin polypeptide.

MAMMALIAN cells infected with SV40 virus carrying cloned eukaryotic genes provide one system in which the expression of eukaryotic genes can be studied[1–3]. SV40 is particularly attractive as a transducing vector for various reasons. The virus genome consists of a single, small, covalently closed circular DNA molecule, whose entire nucleotide sequence has recently been determined[4,5]; the viral DNA is obtainable in large quantities and relatively pure form; the genomic regions responsible for the various viral functions have been accurately located with respect to a detailed physical map of the DNA[4–7]; the viral genome can multiply vegetatively or as an integral part of cellular chromosomes; and a wealth of information exists on the replication and expression of the viral genome and their regulation in different host cells.

To date a number of genes have been recombined *in vitro* with SV40 vectors and propagated in cultured monkey kidney cells; these include segments of λ phage DNA[1,2], *Escherichia coli* DNA coding for tRNA^{Tyr} (ref. 3), thymidine kinase (S. P. Goff and P. Berg, in preparation), guanine phosphoribosyl transferase (R. C. Mulligan and P. Berg, unpublished) and *Drosophila melanogaster* DNA containing the genes for H2A and H4 histones (H. Hofstetter and P. Berg, unpublished). Although the exogeneous DNA segments are transcribed during infections with each of these recombinant genomes, discrete, mature functional mRNAs have not been detected.

We report here the construction and propagation of a recombinant genome in which virtually all of the coding sequence for the major capsid protein, VP1, located between map coordinates 0.945 and 0.145 (see Fig. 1*a*) has been replaced by a cDNA that specifies the entire amino acid sequence of rabbit β-globin[8,9]. Cells infected with the recombinant genome

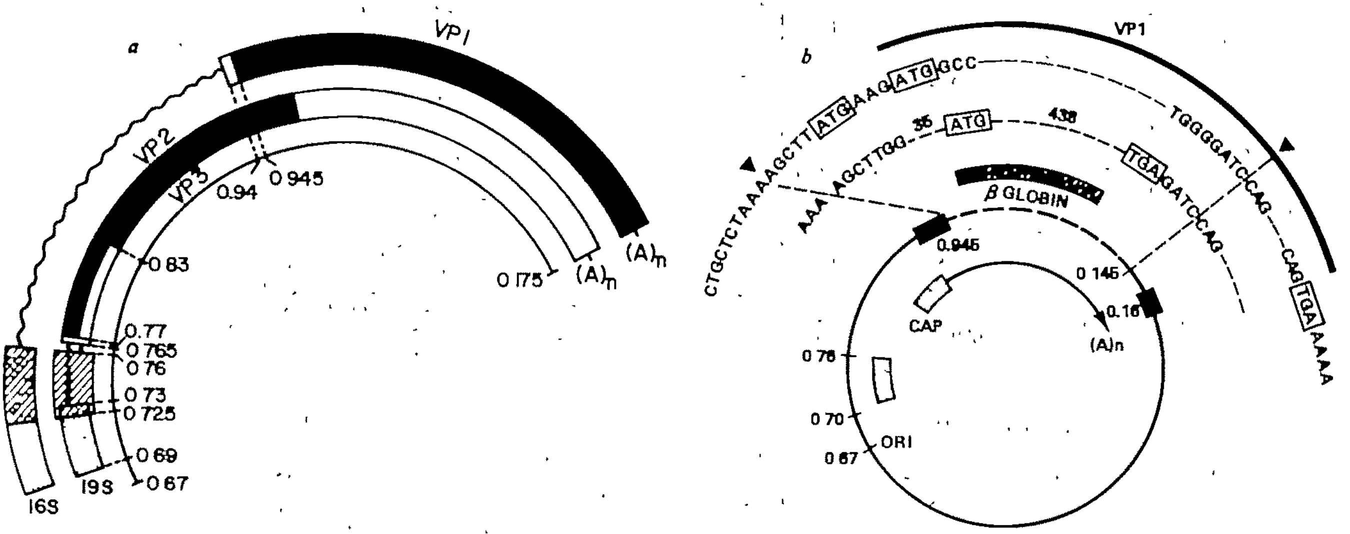

Fig. 1 *a*, The composite structure of SV40 late mRNAs. The map of SV40 DNA from the origin of DNA replication (0.67) to the end of the late region (0 175) is shown on the inner circle The regions coding for the structure of VP1, VP2 and VP3 appear as shaded regions within bars that define the 'bodies' of the 19S and 16S mRNAs. The 'leader' segments are shown as bars spanning map coordinates 0.69–0.76. The cross-hatched and stippled regions of the 16S mRNA leader, for example, are intended as symbolic, rather than literal representations of more than one type of leader segment; one leader segment spans the region from 0.725 to 0.76 ▩ and another the region from 0 69 to 0 76 ☐. For the 19S mRNA species, one class of leaders spans map coordinates 0 69 to 0 73 ☐ and is joined to the body at 0 76; another class of leaders extends from 0 725 to 0 76 ▩ *b*, SV40 and rabbit β-globin cDNA nucleotide sequences relevant to the construction of SVGT5–RaβG The origin of SV40 DNA replication at map position 0.67 is denoted as ori. SV40 16S late mRNA, with its 'capped' 5′ leader sequence derived from 0.72 to 0.76 map units (stippled box), and 3′ poly(A), is represented inside the circle. The region of the map coding for VP1 is represented by the heavy black line labelled VP1. The regions of SV40 DNA implicated in splicing and polyadenylation of the 16S mRNA are shown as black rectangles on the circular map. The dashed line extending leftward from map position 0 945 indicates the position of a *Hin*dIII endonuclease cleavage site in SV40 DNA (the outer sequence) and in pBR322–βG2 DNA (the inner sequence) The dashed line extending rightward from map position 0.145 locates the unique *Bam*HI restriction site of SV40 DNA (outer sequence) and the *Bgl*II endonuclease cleavage site of pBR322–βG2 (inner sequence). The nucleotide sequences between these dashed lines show the β-globin cDNA sequences inserted into SVGT5 and the SV40 sequences excised to construct SVGT5 The triplets enclosed in boxes show the initiation and termination signals for translation of VP1 and β-globin. The β-globin cDNA sequence in pBR322–βG2 contains 35 nucleotides proximal to the initiator AUG in β-globin mRNA The small hatched bar spans the region containing the initiation β-globin codon, the 438 nucleotides specifying the entire β-globin protein amino acid sequence, and the translation terminator codon

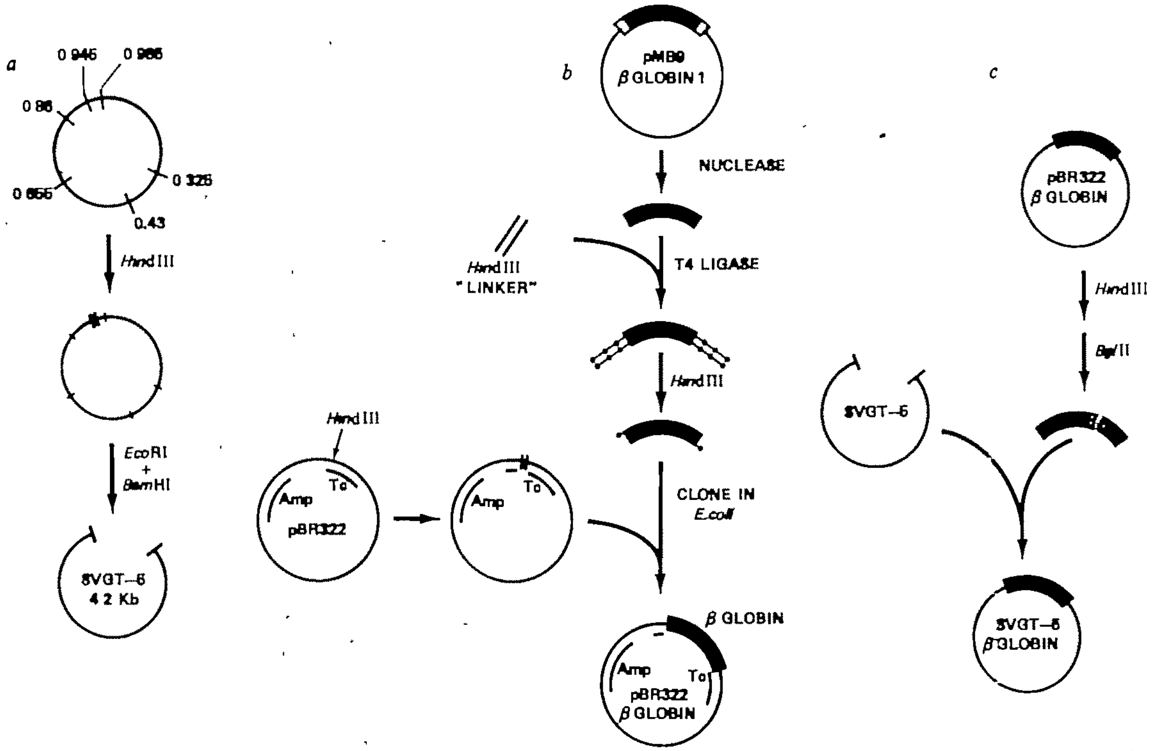

Fig. 2 Construction of SV40-Raβ G recombinant genome *a*, Construction of SVGT5 vector. Approximately 100 μg of SV40 DNA were incubated with 100 U of *Hin*dIII endonuclease (Boehringer) for 50 min at 30 °C in 10 mM Tris, *p*H 7.5, 5 mM $MgCl_2$, 50 mM NaCl, 1 mM DTT The partial digest was electrophoresed on a 0.8% agarose gel in Tris–borate buffer [6] to obtain full-length linear DNA molecules The full-length linear DNA band was eluted electrophoretically from an excised gel slice, digested with an excess of *Bam*HI endonuclease (N E. Biolabs) in 6 mM Tris, *p*H 7.5 containing 6 mM β-mercaptoethanol and 6 mM $MgCl_2$, then, after adjusting the Tris to 100 mM, the mixture was digested with an excess of *Eco*RI endonuclease (N E Biolabs). The digest was electrophoresed on a 0.7% agarose gel and the largest band (4.2-kilobase) was excised and electroeluted To remove residual agarose, the DNA was absorbed to a 0.5 ml DE-52 column equilibrated with TE (10 mM Tris, *p*H 7.5, 1 mM EDTA), after washing the column with TE the DNA was eluted with TE containing 1 M NaCl. *b*, Subcloning of β-globin cDNA PβG1 DNA was incubated with 1,200 U of S_1 nuclease (Miles) for 30 min at 50 °C in buffer containing 30 mM sodium acetate (*p*H 4.5), 1 mM $ZnSO_4$, 0.2 M NaCl and 45% (w/v) formamide[17]. The digestion was terminated by the addition of 10 mM EDTA, the DNA was precipitated with ethanol and electrophoresed in a 5% acrylamide gel in Tris–borate buffer for 3 h at 125 V. The ethidium bromide stained band containing the β-globin cDNA (0.5–0.58 kilobases) was excised and electroeluted One μg of the β-globin cDNA was incubated with 3 μg *E.coli* polymerase I (provided by A. Kornberg) in 25 μl containing 60 mM Tris, *p*H 7.5, 8 mM $MgCl_2$, 10 mM β-mercaptoethanol, 1 mM ATP, and 0.2 mM of each of the deoxynucleoside triphosphates for 10 min at 12 °C to convert 'ragged' into 'blunt' ends[16] ^{32}P-labelled CCAAGCTTGG oligonucleotide (obtained from Collaborative Research) was added in a 50-fold molar excess relative to the cDNA termini and the reaction adjusted to contain 1 mM ATP. T4 DNA ligase (Bethesda Research Laboratory) (50 U ml^{-1}) was added, the mixture (50 μl) incubated for 1 h at 20 °C and then heated at 80 °C for 5 min After adjusting the salt concentration to 50 mM, *Hin*dIII endonuclease (15 units) was added and after 4 h at 37 °C, the digest was electrophoresed on a 5% acrylamide gel The β-globin cDNA band was located by autoradiography, excised, and electroeluted Approximately 0.7 μg of the recovered DNA was mixed with 1.2 μg of *Hin*dIII endonuclease-cleaved pBR322 DNA in 50 mM Tris buffer, *p*H 7.8, containing 10 mM $MgCl_2$, 20 mM DTT, and 1 mM ATP (ligase buffer), 5 units of T4 DNA ligase were added and after an overnight incubation at 12 °C, suitable dilutions of the ligated mixture were introduced into HB101 (ref. 20). Transformants were selected on agar medium containing 20 μg ml^{-1} ampicillin. Approximately 10^4 Amp^r transformants were obtained per μg of ligated DNA. Amp^r colonies were picked onto agar medium containing 50 μg ml^{-1} tetracycline to identify recombinant plasmids with insertions at the *Hin*dIII restriction site[21]. Ten of 22 Tet^s clones carried plasmids containing the β-globin insert One isolate pBR322–βG2, served as the source of β-globin cDNA for insertion into SV40 DNA *c*, Construction of SVGT5–RaβG. pBR322–βG2 DNA was cleaved sequentially with an excess of *Bgl*II and *Hin*dIII endonucleases in the buffers and conditions described above. The products were electrophoresed on a 4% acrylamide gel and the 485-base pair β-globin cDNA band was excised and electroeluted. Approximately 12 ng of the cDNA were incubated with 100 ng of SVGT5 DNA and T4 DNA ligase (25 U ml^{-1}) in ligase buffer overnight at 12 °C. Dilutions of the ligated DNA and *ts*A58 DNA were used to transfect CV-1P cells as already described[22] Fifty plaques were picked and (their viral DNAs) screened for the presence of β-globin cDNA sequences by a modification of the plaque hybridisation method of Villarreal and Berg[23]. A plate of confluent CV-1P cells (100 cm) was overlaid with 40 ml of agar medium and wells, 0.5 cm in diameter, were punched to expose small areas of the cell monolayer. An aliquot (10 μl) of each plaque suspension was added to a well, and after a 2 h incubation at 37 °C, the wells were filled with agar medium After 3 d at 41 °C, the plate was overlaid with agar medium containing 0.01% Neutral Red and incubated overnight at 39°C The agar layer was removed and the cell monolayer transferred to a nitrocellulose disk[23]; the disk was annealed with [^{32}P]-pBR322–βG2 DNA, washed and autoradiographed Forty-six of the 50 plaques picked showed unmistakable evidence of hybridisation, thereby indicating the presence of β-globin cDNA sequences

(SVGT5–RaβG) produce substantial quantities of discrete hybrid mRNAs that contain the β-globin coding sequence flanked by 5′–'leader' and 3′–terminal sequences characteristic of late SV40 mRNAs. The infected cells also synthesise rabbit β-globin polypeptide in quantities nearly equivalent to the amount of VP1 produced by the co-infecting helper virus.

Construction of SVGT5–RaβG

The mRNAs which code for SV40's three capsid proteins, VP1, VP2 and VP3 are composite structures, that is, the mRNAs contain nucleotide sequences transcribed from non-adjacent DNA segments[10,11]. Each mRNA contains a 5′–terminal segment (the leader) transcribed from the l-strand between map coordinates 0.69 and 0.76 (see Fig. 1*a*). Joined to the leader sequence, the VP2 and VP3 mRNAs (the 19S class) have a segment of RNA homologous to the l-strand between map coordinates 0.77 and 0.175 (the 19S body); the body of the VP1 mRNA (16S class) is transcribed from the l-strand of the DNA between map coordinates 0.94 and 0.175.

Deletion mutants have been obtained which lack the 3′ boundary of the late region leader segments[12]. RNA transcribed from these mutants is not processed into mature 16 or 19S mRNA, presumably, because splicing cannot occur. Previously constructed SV40 vectors resemble these deletion mutants in that they have lost most or all sequences required for splicing. Very possibly the failure to obtain discrete mRNAs with the earlier recombinants stems, at least in part, from the consequent disruption of post-transcriptional splicing reactions. We have therefore sought to construct a SV40 vector which would retain all the regions implicated in transcriptional initiation and termination, splicing and polyadenylation of 16 and 19S mRNAs (see Fig. 1*a*).

Inspection of the SV40 restriction map suggested two restriction endonuclease-cleavage sites that could be used to generate such a vector. The first, a *Hin*dIII restriction site at map position 0.945, is six nucleotides proximal to the initiation codon for VP1 (refs 4,5) and about 50 nucleotides distal to the site at which the leader sequence is joined to the body of the VP1 mRNA[13,14] (see

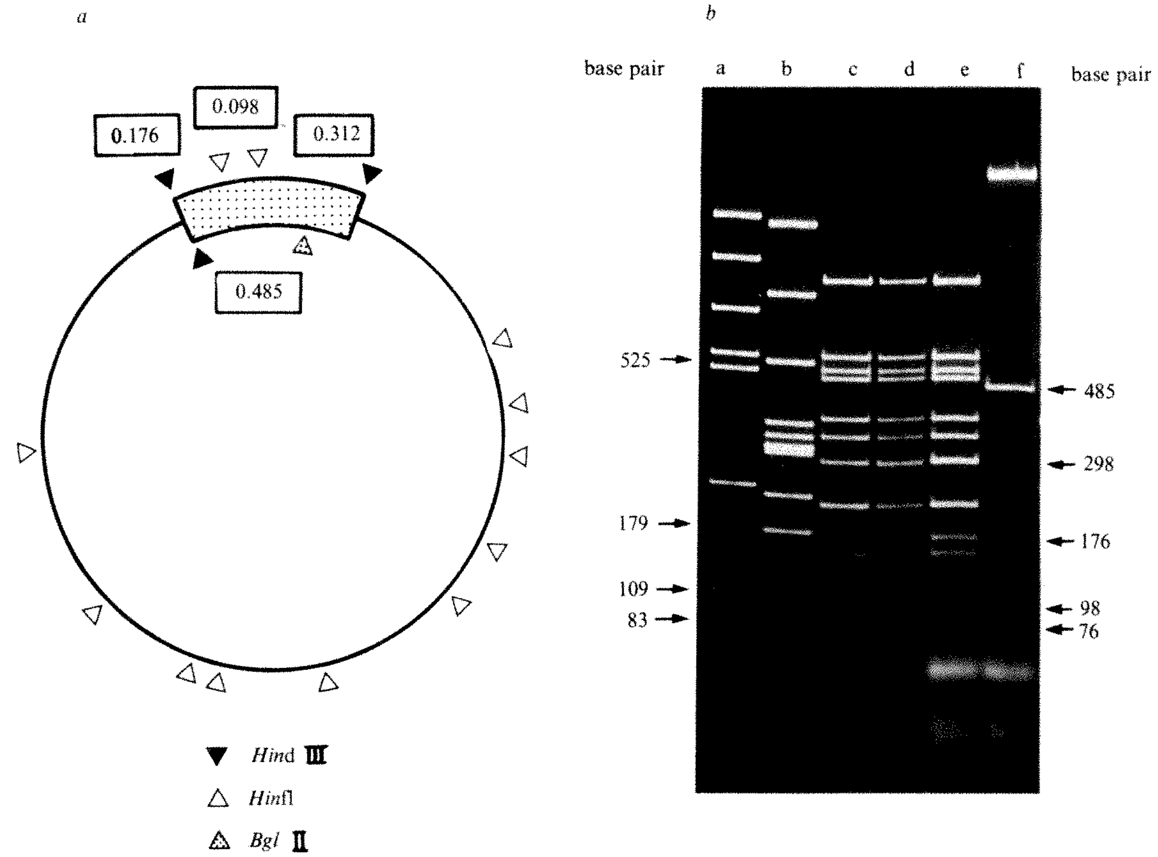

Fig. 3 Restriction analysis of pBR322–βG recombinants. *a*, The numbers in boxes are the expected sizes of restriction fragments, assuming the recovery of the complete cDNA sequence present in PβG1. The stippled region denotes the position of the β-globin cDNA insert and the various symbols indicate the particular restriction endonuclease cleavage sites. *b*, pBR322–βG DNAs were isolated as described by Katz *et al.*[40], digested with an excess of the indicated enzymes and electrophoresed on a 3–7% gradient acrylamide gel[6]. The gel was stained with ethidium bromide (1 μg ml^{-1}) and photographed under short wave ultraviolet light, using Polaroid 665 film and an orange filter. a, *Hin*fI endonuclease digested SV40 DNA. b, *Hae*III endonuclease digested SV40 DNA. c–e, *Hin*dIII plus *Hin*fI endonuclease digested pBR322, pBR322–βG2, pBR322–βG3 DNAs, respectively. f, *Hin*dIII plus *Bgl*II digested pBR322–βG2 DNA.

Fig. 1*b*). The second, a *Bam*HI restriction site at map coordinate 0.145, is 50 nucleotides proximal to the termination codon for VP1 translation and 150 nucleotides before the poly(A) sequence at the 3′-end of VP1 mRNA[4]. The 4.18 kilobase DNA segment bounded by these two restriction sites (SVGT5) contains, in addition to the regions at which splicing and polyadenylation of late mRNAs occur, the origin of DNA replication and the entire early region; hence, it can be propagated by complementation with an appropriate *ts*A mutant[15].

The rabbit β-globin cDNA sequence was selected as the transducible gene because it is small enough to be accomodated in SVGT5 and because the protein can be isolated and characterised readily. Furthermore, the cDNA had already been cloned in *E. coli* and shown to contain the complete coding sequence for β-globin, as well as additional 5′ and 3′-terminal nucleotide sequences present in β-globin mRNA[9]. Our aim was to excise the β-globin cDNA segment from pMB9, modify and reclone it in another *E. coli* plasmid, pBR322 (ref. 16); in doing this we could obtain the β-globin cDNA segment with a *Hin*dIII cohesive end just proximal to β-globin's initiator codon (see Fig. 1*b*). Consequently, SVGT5 and the modified β-globin cDNA segment could be joined readily to form the desired recombinant genome.

Construction, propagation and characterisation of SVGT5–RaβG genomes

To obtain SGVT5, wild-type SV40 DNA was partially digested with *Hin*dIII endonuclease to produce full-length linear molecules (Fig. 2*a*). Full-length linear DNAs were isolated by electrophoresis in agarose gel and digested with *Bam*HI and *Eco*RI endonucleases. These cleavages, and the subsequent electrophoretic separation, yielded a SV40 DNA fragment of 4.18 kilobases which contained the nucleotide sequences between map coordinate 0.145, clockwise to the *Hin*dIII restriction site at map coordinate 0.945. The *Eco*RI endonuclease digestion was introduced to eliminate a potentially contaminating fragment of 4.28 kilobases formed by cleavages at map position 0.325 (a *Hin*dIII restriction site) and the *Bam*HI restriction site at 0.145.

The rabbit β-globin coding sequence was isolated from the PβG1 plasmid recombinant described by Maniatis *et al.*[8].PβG1 was obtained by inserting a cDNA copy of purified rabbit β-globin mRNA at the *Eco*RI restriction site of the plasmid pMB9 using the poly(dA):(dT) joining method, and propagating the recombinant plasmid in *E. coli* (strain HB101)[8]. Nucleotide sequence analysis confirmed that PβG1 contained the entire β-globin coding sequence, all of the 3′ and most (43 of 56 bases) of the 5′-non-coding sequences in β-globin mRNA[9].

PβG1 DNA was digested with S_1 nuclease as described by Hofstetter *et al.*[17] to excise the β-globin cDNA segment from PβG1 (Fig. 2*b*). β-Globin cDNA fragments varying in size between 500–585 base pairs were recovered by electrophoresis in acrylamide gels and incubated with *E. coli* DNA polymerase I and the four deoxynucleoside triphosphates to convert 'ragged' into 'blunt' ends[16]. A decanucleotide 'linker', CCAAGCTTGG, containing the *Hin*dIII endonuclease recognition sequence, was phosphorylated at its 5-end with polynucleotide kinase and $[\gamma-{}^{32}P]ATP$[18] and then joined to the ends of the β-globin cDNA with T4 ligase[19]; subsequent digestion with *Hin*dIII endonuclease generated *Hin*dIII cohesive ends.

The β-globin cDNA with its *Hin*dIII cohesive ends was ligated to *Hin*dIII endonuclease-cleaved pBR322 with T4 DNA ligase, and introduced into *E. coli* K12 (strain HB101)[20]. Transformants were selected for ampicillin resistance and pBR322–βG recombinants were screened for their sensitivity to high levels of tetracycline. (Cells containing pBR322 are resistant to ampicillin and tetracycline, but insertions at the *Hin*dIII restriction site eliminate resistance to high levels of tetracycline[21].) Small cultures of each putative pBR322-βG recombinant were grown, the plasmid DNA was isolated, cleaved with *Hin*dIII endonuclease and the products electrophoresed in agarose; 10 of 22 isolated plasmid DNAs yielded fragments 0.50 to 0.58 kilobases in addition to the linear pBR322 DNA (data not shown).

One of these, pBR322-βG2, produced an insert fragment of about 570 base pairs following *Hin*dIII endonuclease digestion. Two fragments, 485 and 76 base pairs long were detected by digesting this plasmid with *Hin*dIII and *Bgl*II endonucleases (Fig. 3 track f). These findings show that the expected *Hin*dIII joins are intact, that they are separated from each other by nearly the expected length of the β-globin cDNA segment and that the single internal *Bgl*II restriction site in the β-globin cDNA is present. These conclusions are reinforced by the double digestions of pBR322-βG2 and pBR322-βG3 with *Hin*dIII and *Hin*fI endonucleases (Fig. 3 tracks d and e). Fragments corresponding to the expected 176 base pair fragment (derived from the 5′-end of the β-globin coding sequence) and 98 base pair fragment (produced from an internal sequence in the cDNA) were readily apparent in the electropherogram. The predicted 312-base pair fragment, generated from the 3′-end of the globin coding sequence, is actually 298 base pairs and is obscured by a fragment of the same size derived from the vector DNA. This was deduced by inspection of the original film in which the staining of the 298-base pair band was more intense than the band migrating behind it. Determination of the nucleotide sequences[18] at the two *Hin*dIII join sites in pBR322-βG2 further supports the restriction enzyme analysis and establishes that 5 nucleotides at the 5′-end, 15 nucleotides at the 3′-end and all of the dA:dT sequences of the originally cloned β-globin cDNA are absent in the β-globin cDNA segment recloned in pBR322 (data not shown).

The β-globin cDNA segment of pBR322-βG2 was excised by sequential digestion with *Hin*dIII and *Bgl*II endonucleases (Fig. 2*c*). This yielded a fragment having the codon for initiating translation of β-globin 37 nucleotides beyond the *Hin*dIII endonuclease-generated cohesive end and the translation termination codon just proximal to the *Bgl*II endonuclease-generated cohesive end. Even though the *Bam*HI (GGATCC) and *Bgl*II (AGATCT) endonuclease recognition sites differ, the cohesive ends generated by the two endonucleases are identical (GATC). Accordingly, the 0.485-kilobase β-globin cDNA fragment could be ligated to SVGT5 with T4 ligase[24] (Fig. 2*c*). To propagate the SVGT5-βG2 genome, CV1-P cells were transfected with a mixture of the ligated DNA and *ts*A58 DNA[22]. *ts*A58 is a thermosensitive mutant of the SV40 early function and can not multiply at 41 °C (ref. 15). About 2.5×10^4 plaques were obtained per microgram of ligated DNA.

These plaques were screened for virus containing the β-globin cDNA using a modification of the *in situ* plaque hybridisation technique[23](see legend to Fig. 2*c*). Forty-six of fifty plaques examined contained DNA that hybridised specifically to the β-globin cDNA. Recombinant virus from independent clones were purified by plaque isolation and high-titre virus stocks and purified viral DNA were prepared in CV1 cells. Judging from the relative yields of the two DNAs from such mixed infections, we estimate that the recombinant and helper genomes multiply equally well.

As expected from its somewhat smaller size (4.7 compared with 5.2 kilobases), SVGT5-βG DNA is separable from the helper *ts*A58 DNA by electrophoresis in agarose (Fig. 4, tracks a–c). Restriction endonuclease digestions and electrophoresis of the products helped to confirm the structure of the hybrid DNA. The locations of the *Hin*dIII and *Mbo*I restriction sites in SVGT5 and the β-globin cDNA sequence are indicated in Fig. 4*a*. Correct joining of the β-globin cDNA to SVGT5 regenerates the *Hin*dIII restriction site at map position 0.945. Therefore, digestion of SVGT5-βG DNA with *Hin*dIII endonuclease should generate a fragment of 1.43 kilobases from cleavages at the *Hin*dIII join sequence and the *Hin*dIII restriction site at map position 0.325 in the vector; the 1.43-kilobase fragment is produced in the *Hin*dIII endonuclease digests of two independent recombinants, SVGT5-βG 10A and SVGT5-βG 12A (Fig. 4, tracks e and f), but is absent from a comparable digest of SV40 DNA (track d). After transfer of the DNA in the gel to a nitrocellulose sheet[25] and hybridisation with [^{32}P] PβG1

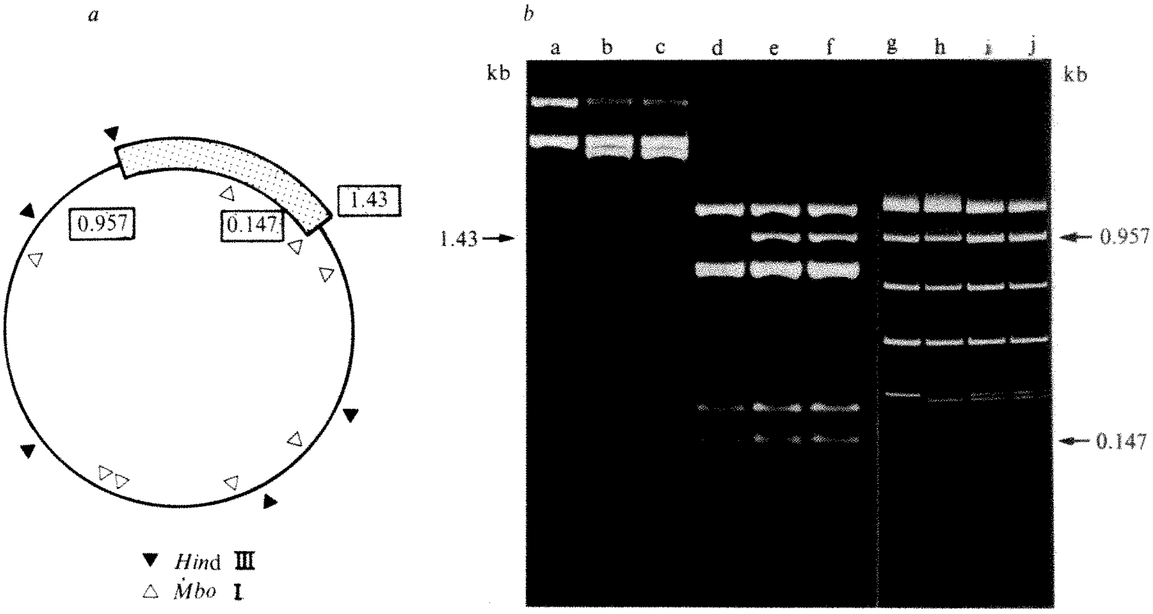

Fig. 4 Restriction analysis of SVGT-RaβG. *a*, The stippled region denotes the β-globin cDNA sequence and the numbers enclosed in boxes are the expected fragment sizes based on the sequence of the β-globin cDNA in pBR322–βG2 and the known locations of the *Hin*dIII and *Mbo*I restriction sites. *b*, Viral DNA was extracted by Hirt's method[27] from CVl cells that had been infected with plaque-purified SVGT5–βG and *ts*A58 virus (M.O.I. 0.005 PFU per cell). The DNA was centrifuged to equilibrium in ethidium bromide–caesium chloride gradients[28]; aliquots were then digested with the appropriate enzymes and electrophoresed on either 0.8% agarose gels (tracks a–f) or on 3–7% gradient acrylamide gels (tracks g–j). Tracks a–c: undigested SV40, SVGT5–βG10A and SVGT5–βG12A DNAs. Tracks d–f: the same three DNAs digested with *Hin*dIII. Tracks g–h: *Mbo*I endonuclease digests of SV40, *ts*A58, SVGT5–βG10A and SVGT5–βG12A DNAs.

DNA, only the 1.43-kilobase fragment was labelled (data not shown); hence, all of the β-globin cDNA sequence is contained within that fragment.

Ligation of *Bam*HI and *Bgl*II endonuclease-created cohesive ends should generate a sequence which is resistant to cleavage by these two enzymes but sensitive to *Mbo*I endonuclease (recognition sequence NGATCN). Indeed, *Mbo*I endonuclease digestion of SVGT5-βG 10A and SVGT5-βG 12A DNAs produced the expected array of fragments (Fig. 4*b*). The 0.957 fragment, which spans the *Hin*dIII join site, comigrates with one of the vector DNA fragments (compare tracks i and j with g and h); the 0.147-kilobase fragment, formed from cleavages at a *Mbo*I restriction site within the β-globin cDNA and the *Mbo*I site formed by the join of the *Bgl*II and *Bam*HI cohesive ends is produced from both recombinants (tracks i and j) but is absent from SV40 DNAs (tracks g and h). Note that the 0.240 fragment produced from the SV40 DNA used to make the vector (track g) is slightly larger than the corresponding fragment cleaved from the *ts*A58 helper DNA (track h). The mixture of recombinant and helper DNA yielded both fragments in about equal amounts indicating that here too the recombinant and helper genomes were equally represented in the infection from which these DNAs were isolated.

Although not shown, 8 of 14 other independent clones of SVGT5-βG gave restriction digests comparable to the two documented here. These data indicate that the β-globin cDNA cloned in pBR322 has been introduced into SVGT5 in the expected way.

Formation of SV40-Ra β-globin hybrid mRNAs

Considering the structure of SVGT5-βG and present ideas about SV40 late mRNA formation, two cytoplasmic SV40–β-globin hybrid mRNAs should be formed following infection with SVGT5-βG. These should be about 0.5 kilobases smaller than the normal SV40 19S and 16S late mRNAs. To test these expectations, CV1 cells were infected with *ts*A58 and each of two SVGT5-βG recombinant viruses (MOI 10–50 PFU per cell) at 37 °C and, after 48 h, cytoplasmic, poly(A)containing RNA (freed from DNA) was isolated (see legend to Fig. 5); similar RNA preparations were isolated from SV40 and mock-infected cultures. Each RNA preparation was denatured with glyoxal[26], electrophoresed on 1.5% agarose gel and transferred to diazotised benzyloxymethyl paper[12,30]. The imprints were annealed with ^{32}P-DNA to reveal the positions of the separated RNAs (Fig. 5).

With [^{32}P] PβG1 DNA as hybridisation probe, two discrete β-globin mRNA species are detectable in the RNA from cells infected with either recombinant (Fig. 5, tracks c and d). These RNAs are missing in the RNA from mock or SV40-infected cells (tracks a and b). With DNA fragments of known size as length standards (tracks e and f) we estimate the sizes of these mRNAs as 1.8 and 1 kilobases. When duplicate tracks were hybridised with [^{32}P]-SV40 DNA containing the late mRNA leader sequences, two labelled bands are visible in the SV40-infected cell RNA (track i), but not in the RNA from mock-infected cells (track j). The faster migrating, more heavily labelled band is the 16S mRNA (1.5 kilobase) and the slower, less heavily labelled band the 19S mRNA (2.3 kilobase). There are four labelled bands when RNA from cells infected with the two SVGT5-βG recombinants is hybridised with the labelled SV40 leader probe (tracks g and h). Two (the 1.5 and 2.3-kilobase species) are the 16S and 19S mRNAs produced by the *ts*A58 helper genome. Another has the mobility of the 1-kilobase RNA species that hybridised to the globin cDNA probe. The fourth, which is only barely discernable in this exposure, has a mobility very close to that of the 1.8-kilobase RNA detected with the β-globin cDNA probe. Thus the 1 and 1.8-kilobase polyadenylated RNAs contain the β-globin cDNA sequence and the leader segment characteristic of SV40 late mRNAs. Comparing the labelling intensities of the 1-kilobase β-globin mRNA and the 1.5-kilobase SV40 mRNA (in Figs, tracks g and h) and taking account of the ratio of recombinant to helper DNA in these infected cultures (0.3 recombinant), we surmise that the steady state levels of the two mRNAs are within a factor of two of each other.

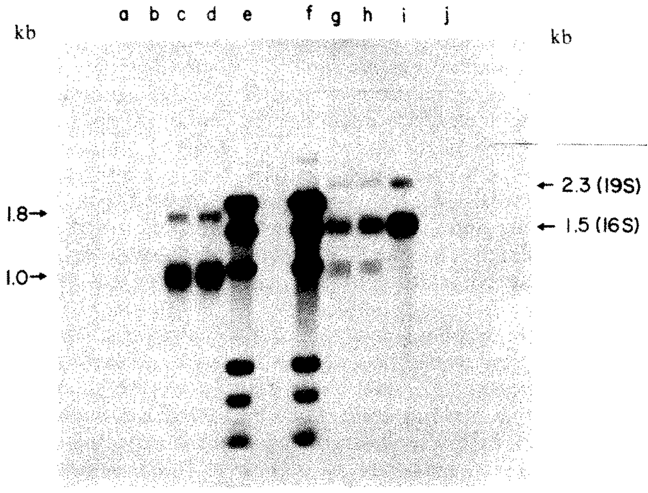

Fig. 5 Analysis of mRNAs made in cells infected with SVGT5-βG. Cytoplasmic poly(A)-containing RNA was isolated from CV1 cells 48 h after infection with a mixture of SVGT5-βG and *ts*A58 virus (>10 PFU per cell) as follows. Cells were washed twice with ice-cold Tris-buffered saline and once with a cold solution containing 10 mM Tris, *p*H 7.5, 5 mM $MgCl_2$, 10 mM NaCl. The cell monolayer, in the latter buffer containing 0.1% NP40 and 0.05% deoxycholate (1 ml per plate), was scraped off the plate with a rubber policeman and centrifuged for 2 min at 1,500 r.p.m. to pellet the nuclei. The supernatant was mixed with an equal volume of solution containing 0.3 M NaCl, 0.1 M Tris, *p*H 8.0, 10 mM EDTA, and 0.15% SDS. Cell aggregates were dispersed by pipetting and the suspension was extracted two times with an equal volume of water-saturated phenol-chloroform (1:1). After ethanol precipitation, the nucleic acid was digested with iodoacetate-treated DNase[29] (Worthington) (20 μg per mg nucleic acid), at room temperature for 45 min in a small volume of 20 mM Tris, *p*H 7.5, 10 mM NaCl, and 10 mM $MgCl_2$. The mixture was extracted twice with phenol-chloroform and passed over poly(U)-Sepharose[41] to isolate poly(A)-containing RNA. Aliquots of the poly(A)-containing RNA were denatured with glyoxal[26] and electrophoresed in a 1.5% agarose gel in 10 mM sodium phosphate *p*H 7.0. The fractionated RNA was then transferred to diazotised benzyloxymethyl paper[30] as described by Villarreal, White and Berg[12]. The paper was annealed with about 4×10^6 c.p.m. of the indicated ^{32}P-nick-translated DNA probe for 24 h, then washed[12] and autoradiographed for 2 d. ^{32}P-labelled pBR322-βG2 DNA fragment (from map position 0.67–0.76, produced by cleavages with *Bgl*I and *Hpa*I endonucleases) was the hybrisation probe for tracks g–j. Tracks e and f contained a *Hin*dII digest of [^{32}P] SV40 DNA as size standards. The lengths of the fragments (kilobases) in decreasing order are: 1.96, 1.54, 1.07, 0.369, 0.240. Tracks a, j; RNA from non-infected cells; b, i SV40 RNA; c, h SVGT5-βG10A RNA; d, g SVGT5-βG12A RNA.

Formation of β-globin

One goal of our experiment was to determine whether replacing the VP1 coding sequence with the β-globin sequence would permit the formation of a discrete, cytoplasmic SV40–β-globin hybrid mRNA. An additional goal was to determine whether such SV40-β-globin hybrid mRNAs could be translated *in vivo* to produce β-globin. CV1 cells were infected with *ts*A58 and either of the two SVGT5-βG recombinants (MOI 10-50 PFU per cell) and, after 48 h (37 °C), the cultures were labelled with ^{3}H-leucine and ^{3}H-valine for 30 min; SV40 and mock-infected cultures were labelled in a comparable way. An extract of each culture was prepared by sonication and treatment with NP40-deoxycholate; aliquots were electrophoresed on a SDS 15–20% gradient acrylamide gel (see legend to Fig. 6). The autoradiograms of each electrophoresed extract had a complex array of labelled protein bands (Fig. 6 tracks a–d). But the patterns from the SVGT-βG infected cell extracts (tracks c and d) contain a protein band migrating at the position of added rabbit β-globin; this protein band is not discernable in either the SV40 or mock-infected cell extracts (tracks a and b). The formation of a β-globin-like protein in cells infected with SVGT5-βG is supported by the fact that a protein with the same mobility as authentic rabbit β-globin can be recovered from complexes formed by incubating the cell extracts with purified goat anti-rabbit β-globin immunoglobulin (kindly provided by S. Boyer, Johns Hopkins) and heat killed, formalin-fixed *Staphylococcus aureus* cells[33]; the electrophoretic pattern of the labelled proteins eluted with SDS and urea from such complexes are shown in tracks e–h. β-globin bands are seen in the extracts from cells infected with the recombinant (tracks g and h), but not in extracts from uninfected and SV40-infected cells (tracks e and f). If the extracts from SVGT5-βG infected cells are mixed with non-immune goat serum (tracks i and j) or anti-SV40 VP1 serum (track k), before adding the *S. aureus* cells, no β-globin is detectable in the electrophoresed samples.

In a preliminary experiment (carried out in collaboration with T. Hunter at the Salk Institute) the putative β-globin protein obtained from cells infected with SVGT5-βG was immunoprecipitated with the immune serum and *S. aureus* cells mentioned above, eluted with SDS, digested with trypsin and analysed by the two-dimensional electrophoretic-chromatographic procedure[36]. The tryptic peptide maps of the putative β-globin and labelled rabbit β-globin synthesised *in vitro*[36] were strikingly similar; at least 8 of 10 peptide spots in the two maps matched (data not shown). Further experiments to characterise the β-globin, particularly the amino and carboxy terminal amino acid sequences, are in progress.

In experiments to be published later we have compared the amounts of β-globin and VP1 synthesised in cells infected with SVGT5-βG and the helper virus *ts*A58. ^{35}S-methionine labelled infected cell extracts were mixed with either anti-β-globin or anti-SV40 VP1 serum, both immune complexes were adsorbed to *S. aureus* cells, washed, eluted with SDS, electrophoresed in SDS–polyacrylamide gel and autoradiographed. The amount of ^{35}S-label in β-globin and VP1 was quantitated by densitometry of their respective bands in the autoradiograms. Taking into account the difference in the number of methionine residues per mole of β-globin and VP1 (1 : 9) and the ratio of SVGT5-βG to *ts*A58 genomes during the period of protein labelling (1 : 3), we estimate that β-globin and VP1 are synthesised at nearly equal rates.

Discussion

These experiments establish that an exogenous gene, in this case the coding segment for rabbit β-globin, can be recombined with SV40 DNA *in vitro* to yield a hybrid genome that expresses the incorporated gene. The principal conceptual innovation is the decision to leave intact the regions in the vector implicated in SV40 late mRNA processing: specifically, the late mRNA leader sequence, the sequence to which the leader is spliced during maturation of late mRNAs, and the region in which late transcripts terminate and are polyadenylated (see Fig. 1*a* and *b*). In the recombinant genome, virtually all of the coding sequence of SV40's major capsid protein VP1 has been replaced by a β-globin cDNA. β-globin's initiator codon, and presumably its ribosome-binding sequence, replace the corresponding initiation sequence of VP1; furthermore, β-globin's translation terminator codon is proximal to the VP1 termination codon remaining in the vector (Fig. 1*b*). This strategy was adopted so that the β-globin coding sequence would be incorporated into mature SV40-β-globin hybrid mRNAs and be translated.

The success of the experiment clearly demonstrates that processing of both the 16 and 19S late mRNAs does not require nucleotide sequences within the VP1 coding region: analogous (smaller) mRNAs with poly(A) and leader sequences are formed efficiently when most of the VP1 coding sequence is replaced by the β-globin cDNA. Detailed studies are needed to compare the nucleotide sequences of wild-type 16 and 19S mRNA leaders with SVGT5-βG's corresponding β-globin mRNA leader sequences; it may also be interesting to compare the relative rates of the various splicing reactions of normal and recombinant RNAs. Another intriguing question is whether the monkey cells can excise the two intervening sequences present in the rabbit β-globin genomic DNA segment (Maniatis, T. *et al.*, in preparation), a question which can be examined with recombinants in which the rabbit β-globin genomic DNA sequence has been inserted into analogous SVGT vectors.

VP1 is believed to be translated exclusively from the 16S mRNA although the protein's coding sequence is also contained within the 19S mRNA[37]. Therefore, β-globin is probably translated from the 1-kilobase SV40-β-globin hybrid mRNA (the 16S mRNA analogue) and not the 1.8-kilobase hybrid mRNA (the 19S mRNA analogue). Conceivably, however, β-globin may be translated from the 19S mRNA analogue as well, either because the altered nucleotide sequence of the large hybrid mRNA significantly affects its secondary structure or because the ribosome binding site for β-globin is functionally independent of its position within a message. Experiments are in progress to insert the β-globin coding sequence at several different locations in the late and early regions of SV40 DNA, making it possible to assess the effect of varying the distance of the β-globin coding sequence from the 5'-end of the mRNA, the role of neighbouring sequences and any regulatory influence on the efficiency of expression—transcription, processing and translation—of the β-globin 'gene'.

Of particular interest is whether other genes can be expressed if they are inserted into appropriate SV40 DNA vectors in a similar way. Hofstetter and Berg (unpublished results) have

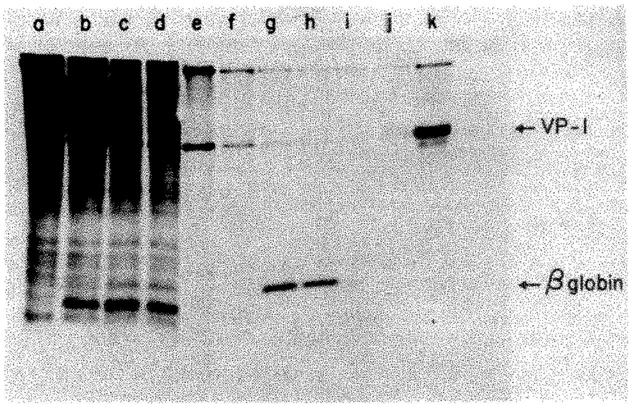

Fig. 6 Production of rabbit β-globin in cells infected with SVGT5-RaβG. Subconfluent CV1 cells were infected with a mixture of SVT5-βG and *ts*A58 (>10 PFU per cell) for 48 h at 37 °C in a medium containing 4% fetal bovine serum. The cells were washed once with Tris-buffered saline and once with medium lacking leucine and valine. Cells were labelled for 30 min at 37 °C with 200 μCi each of ^{3}H-leucine and ^{3}H-valine (Amersham-Searle) in 1 ml of medium containing 4% dialysed calf serum but lacking leucine and valine. The labelled cells were washed twice in ice-cold Tris-buffered saline, scraped off the plate in Tris-buffered saline containing 10 mM DTT and 250 μg ml^{-1} PMSF (added fresh) (1 ml per 100 cm plate)[31] and then sonicated for 2 min in a water-cooled Heat Systems sonicator cup horn (maximum setting). Extracts were made 0.1% in NP40 and 0.05% in deoxycholate, incubated on ice for 10 min, centrifuged at 18,000 r.p.m. for 30 min, and the supernatants stored in aliquots at −80 °C. Aliquots of each extract were reacted with specific antisera or antibody proteins according to the method of Padgett *et al.*[32]. Extracts of approximately 2.5×10^6 cells were preincubated with 50 μl of a 10% suspension of heat-killed formalin-fixed *Staphylococcus aureus* Cowen I bacteria[33] in 25 mM Tris, *p*H 7.4, 10 mM EDTA, 0.35 M NaCl, and 0.15% Triton X-100 (TENT buffer) for 15 min on ice. After removal of the bacteria by centrifugation, purified rabbit β-globin (1 μg) and an excess of either purified goat anti-rabbit β-globin immunoglobulin (provided by S. Boyer, Johns Hopkins), normal goat serum (Microbiological Associates), or rabbit anti-VP1 serum (provided by J. Reiser, Stanford) was added and the extracts incubated overnight at 4 °C. Then 50 μl of *S. aureus* suspension (as described above) were added, the mixtures were incubated for 10 min at 4 °C, and centrifuged for 2 min at 8,000 r.p.m The bacterial pellet was washed four times with TENT buffer and the immune complexes eluted from the bacteria for 1 h in a solution containing 10 mM Tris *p*H 7.4, 1% SDS, and 8 M urea. Electrophoresis of cell extracts or of immune complexes prepared from those extracts was for 3 h at 125 V in a 15–20% gradient acrylamide–SDS gel prepared according to the method of Laemmli[34]. The gel was stained and fluorographed[35] (3-day exposure shown). Tracks a–d are untreated cell extracts; e–h are immune complexes from extracts reacted with goat-anti-rabbit β-globin immunoglobulin; a,e, uninfected cell extract; b,f, SV40-infected cell extract; c,g, SVGT5-βG10A-infected cell extract; d,h, SVGT5-βG12A-infected cell extract. Tracks i,j: immune complexes prepared from SVGT5-βG10A (i) or SVGT5-βG12A (j) infected cell extract reacted with normal goat serum; k, immune complex prepared from SVGT5-βG10A-infected cell extract reacted with rabbit anti-VP1 serum.

inserted a *Drosophila melanogaster* (Dm) DNA segment containing the gene for histone H2B into SV40 DNA (between map positions 0.825 and 0.145) and observed the formation of both a cytoplasmic, polyadenylated SV40-Dm H2B hybrid mRNA and H2B protein during multiplication of the recombinant in monkey cells. Experiments are in progress to examine the expression of a variety of prokaryotic, lower eukaryotic and mammalian genes in mammalian cells using this approach.

SVGT5-RaβG may prove invaluable for testing the effects of mutational alterations on the regulation of SV40 transcription. Deletions could be introduced into those portions of the vector DNA that are implicated in viral mRNA formation and their consequences determined, even in the presence of helper genomes, by monitoring β-globin mRNA and protein synthesis. This approach will be particularly advantageous where the mutational changes either prevent or have no effect on the transcription of particular messages. More generally, this system may be used in conjunction with new methods for site-directed mutagenesis[38,39] to 'synthesise' altered eukaryotic mRNA structures at the DNA level, and to examine their function *in vivo*.

SVGT5-RaβG should be able to transform a variety of mammalian cells, such as mouse, rat and human. Since integrated SV40 genomes do not express the late region, SVGT5-βG transformed cells are not likely to make β-globin mRNAs or β-globin. However, other vectors, which permit transcription of the exogenous gene under early control are being explored for their ability to promote expression of the integrated genes.

β-Globin made during infection of CV1 cells by SVGT5-βG is not stable; following a 30-min labelling period most of the newly synthesised β-globin disappears during a 60 min chase (data not included). Several explanations come to mind: the newly synthesised polypeptide is an altered form of β-globin; factors in the monkey cell cultures actively promote breakdown of β-globin chains; cultured monkey kidney cells lack factors normally present in erythroid cells that stabilise β-globin. Our agenda includes experiments to characterise further the structure of rabbit β-globin synthesised in monkey cells and to determine if the β-globin can be stabilised, perhaps by the addition of haemin to the culture medium or the concomitant production of rabbit α-globin by co-infection with a SVGTαG recombinant genome.

We thank Dr T. Maniatis for providing the *E. coli* culture harbouring the β-globin recombinant plasmid PβG1. All experiments involving the construction and propagation of recombinant genomes were performed according to the stipulations in the existing NIH guidelines: P2 for PβG1 and pBR322-βG and P3 for SVGT5-βG. This research was supported by research grants NIH GM 13235-13 and NCI CA 15513-05. Richard C. Mulligan is a NSF Fellow and Bruce H. Howard is an Investigator in the USPHS.

Interstellar reddening and distance of Nova Cygni 1978

THE interstellar feature of KI(λ7699 Å) has been observed in the direction of Nova Cygni 1978 with an equivalent width of $W_\lambda \simeq 116$ mÅ and has been used here to deduce a colour excess of $E(B-V) = 0.38 \pm 0.08$ mag. The distance–reddening law to the nova is derived from a sample of stars in the nearby field surrounding the nova. The nova seems to be at a distance of $r \simeq 3.3 \pm 0.6$ kpc with a corresponding absolute visual magnitude at maximum light of $M_{V_0} \simeq -7.5 \pm 0.5$ mag. Nova Cygni 1978 is classified as a fast galactic nova on the basis of its absolute magnitude at maximum light and the rate of decline towards minimum light.

A composite light curve for Nova Cygni 1978 is shown in Fig. 1; the data are a mixture of visual, photographic (prediscovery) and photoelectric measurements[1–3]. A polynomial fit to the data yields a time of maximum light of $t_m = 12.20 \pm 0.04$ September 1978 (UT) when the nova attained a brightness of $m_v \simeq 6.2 \pm 0.1$ mag. Near maximum light and thereafter, high resolution spectra (220 mÅ) were obtained of the nova using the 2.7-m telescope of the McDonald Observatory with a self-scanned Reticon 1024B detector[4] and the coudé spectrograph.

In addition to monitoring various emission features, including Hα, Hβ, OI(λ8446 Å), and HeI(λ10830 Å), spectra were also obtained of the NaI(λ5890 Å) and KI(λ7699 Å) interstellar lines.

The interstellar NaI lines are very strong, having equivalent widths ~550 mÅ; NaI lines arising from the nova are also seen displaced by 626 km s^{-1} to the blue. The KI line, shown in Fig. 2, is weaker and seems to contain two unresolved components. From the measured equivalent width of the KI line ($W_\lambda \simeq 116$ mÅ) a column density of $N(\mathrm{KI}) \simeq 9.3 \times 10^{11}$ cm^{-2} is

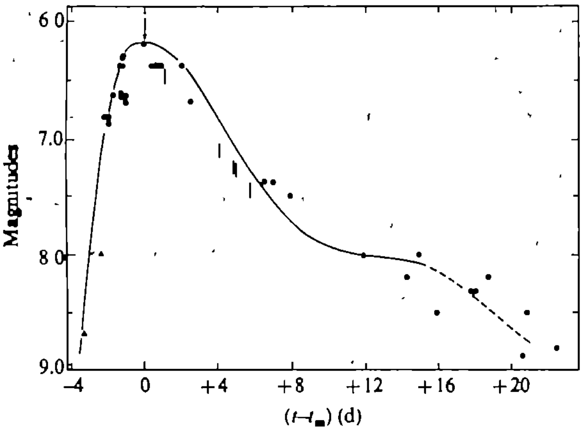

Fig. 1 Composite light curve for Nova Cygni 1978. ▲, Prediscovery photographic values; ●, photoelectric observations; ○, visual observations. Time of maximum light, t_m, (arrow) and the epochs of the spectroscopic data (vertical lines) are indicated. Solid curve approximates behaviour of nova during rise to maximum and early decline.

deduced. This column density can be converted in the $E(B-V)$ colour excess using the mean relationship[5]

$$N(KI) = 6.4\times10^{12}\cdot E(B-V)^2$$

which yields a value of $E(B-V)\simeq0.38\pm0.08$. A higher value of $E(B-V)\simeq0.6$ has been reported[6] from measurements made of both the interstellar K and D_2 lines. Recently, a lower limit of $E(B-V)=0.18$ was determined from linear polarisation measurements[2]; a value of $E(B-V)=0.3$ $(+0.2/-0.1)$ was also reported[1] from an observation of the diffuse interstellar feature at λ6614.

The data given in Table 1 are tabulated for 16 stars[7] in the field near the nova and are used to derive the distance–reddening relationship shown in Fig. 3. The solid line is representative of the general trend. The exact form of the relationship becomes increasingly uncertain beyond 1 kpc due to the paucity of stars with large colour excesses.

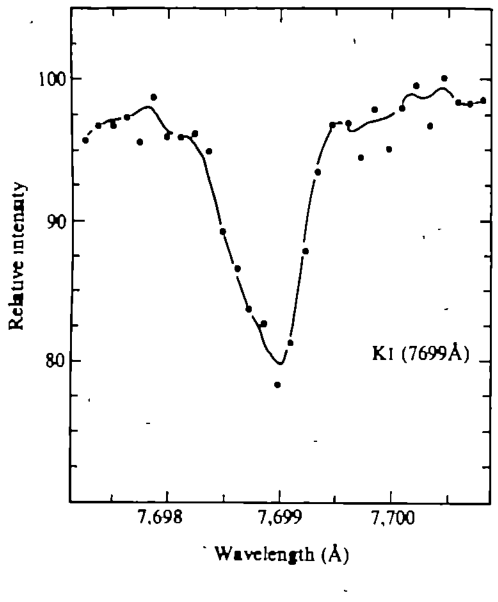

Fig. 2 The KI(λ7699 Å) interstellar feature ($W_\lambda\simeq116$ mÅ) as observed on 16.36 September 1978 (UT). ●, Observed points; Fourier fit indicated by solid line.

* Ref. 7.

† Luminosity class in parentheses assumed.

A values of $E(B-V)=0.38$ indicates that the nova is located at a distance of $r\simeq3.3\pm0.6$ kpc where the error is estimated from the uncertainty in the distance–reddening law. The visual absorption corresponding to this colour excess is found to be $A_v=R\cdot E(B-V)\simeq1.1$ mag (assuming $R=3.1$) and indicates a value of the corrected apparent visual magnitude at maximum light to be $V_0=m_v-A_v\simeq5.1$ mag. Combined with the above estimate for the distance, this implies a value of $M_{V_0}\simeq-7.5\pm0.5$ mag was reached by the nova at maximum light.

Since the time of maximum, the nova has declined at a rate of ~0.13–0.17 mag d^{-1}. Using the speed classes defined by McLaughlin[8], Nova Cygni 1978 appears as a fast galactic nova, comparable to other fast novae such as EI Aql ($M_V\sim-7.35$) and DI Lac ($M_V\sim-7.3$). Assuming a value $B\sim20$ for the nova precursor[9] implies an absolute magnitude for the precursor of $M_B\sim7$ mag.

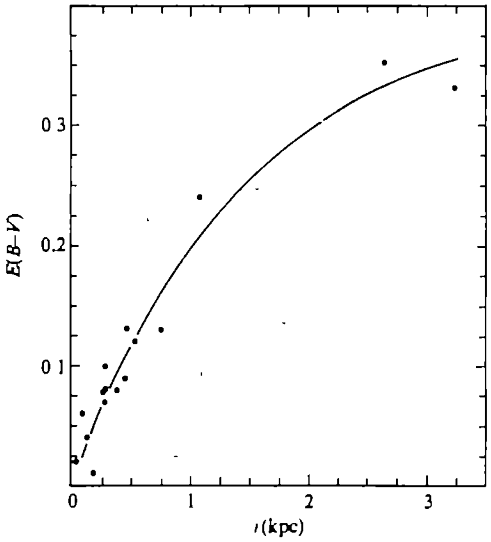

Fig. 3 The distance–reddening law in the direction of the nova. The solid points represent the data from Table 1; the line indicates the form of the reddening curve which is only approximately represented beyond 1 kpc.

Is Crab nebula a disrupted helium star?

WE propose here that the Crab nebula was produced by the explosion of a helium star in a close binary already containing a neutron star. This explosion would be caused by a complete spiralling of the neutron star into the helium star, which was totally disrupted[1]. The neutron star would be spun up in the process and be identified with PSR0532.

Arnett has pointed out that the overabundance of helium with respect to hydrogen in the Crab filaments[2] is compatible with a presupernova helium core of mass 4 $M_{\odot}$ (ref. 3) which corresponds to a main sequence mass of 12 $M_{\odot}$ (ref. 4). Chevalier[5], on examining old Chinese records, present day nebula and the embedded pulsar, finds that all available information is consistent with the Crab having a massive progenitor. The fact that the motion of the Crab pulsar is directed away from the I Gem association has led to the suggestion[6] that the progenitor of the Crab was a runaway star from I Gem. According to this model, the first supernova explosion in a close binary in I Gem disrupted the binary releasing a neutron star (identified with PSR0527) and a normal star of mass 12 $M_{\odot}$ which later exploded to give the Crab nebula and the pulsar.

The model of a massive progenitor for the Crab as discussed above presents some problems. First, detailed work on the evolution of close binaries in the context of compact X-ray sources has shown (see ref. 1) that the first supernova explosion in a mass transfer binary is unlikely to disrupt the system. (If the binary is sufficiently wide so that mass transfer does not take place, the velocity of the normal star at the time of the disruption of the binary—equal to its orbital velocity—would be very small). Thus we are faced with the problem of placing a massive progenitor for Crab at $|z| = 200$ pc. Second, to avoid an observable overabundance of heavy elements in the Crab filaments, it must be assumed[3] that the explosion of the helium star leaves behind a 1.45 $M_{\odot}$ neutron star core. Now this value is substantially larger than 0.5 $M_{\odot}$ estimated for the Crab pulsar on the basis of detailed models of neutron stars and data on micro- and macroglitches[7]. Third, there is the crucial problem of the mass. For the nebula a total mass of ~1 $M_{\odot}$ has been estimated from the absolute intensities of emission lines[8]. On the other hand, Davidson *et al.*[9] conclude that a nebular mass in the range 0.3–10 $M_{\odot}$ would not be inconsistent with observations, most of the mass being in dense neutral cores of filaments. However, the fact that bright and faint filaments have been accelerated equally, argues against the presence of too much neutral matter[10]. The mass of the nebula is therefore unlikely to be very much greater than 1 $M_{\odot}$. Thus the problem is that if the Crab is a result of the supernova explosion of a massive star, where is the remaining mass?

These problems are solved if we assume that the progenitor of the Crab was a mass transfer binary. It is then obvious that the event of 1054 could not have been the first supernova explosion, because such an explosion would leave the binary intact. In other words the progenitor binary of the Crab must have passed through a Cen X3 type X-ray stage. The evolution of a normal massive star in a close binary containing a neutron star is characterised by a tremendous loss of mass and angular momentum[11–13]. The normal star expands and engulfs the neutron star, which leads to a rapid shrinkage of the orbit[14]. The spiralling in of the neutron star terminates when only the helium core of the companion is left, the hydrogen rich envelope having been blown off[13]. For example[15], starting with an X-ray binary consisting of a 1 $M_{\odot}$ neutron star and a 15 $M_{\odot}$ normal star, we may arrive at a system consisting of a 1 $M_{\odot}$ neutron star and a 3 $M_{\odot}$ helium star and having a period of ~1.5 h corresponding to a separation of about 1 $R_{\odot}$.

It has implicitly been assumed[16,17] that the helium star now evolves as a single star, so that its explosion in most cases distrupts the binary releasing two neutron stars, the old spun up neutron star manifesting itself as a type L pulsar and the newborn as a type D pulsar. However, conditions may be such that the helium star does not evolve as an isolated star. A 3 $M_{\odot}$ helium star has a radius of 1.4 $R_{\odot}$ at the onset of carbon ignition and of 4.5 $R_{\odot}$ at the onset of neon burning[18]. Thus if the separation between the two stars is sufficiently small, at some point in the evolution of the helium star the neutron star would be engulfed, triggering off a new spiralling in, which may totally disrupt the helium star and spin up the neutron star to very short periods[1].

According to our hypothesis, the Crab nebula is such a disrupted helium star and the Crab pulsar, a spun up old neutron star (a type L pulsar). This model has many attractive features. It provides a helium star for explosion without an embarassingly large mass for the nebula. It explains the observed overabundance of helium without postulating an excessively heavy neutron star or an unwanted excess of heavy elements. In this context it is relevant that Arnett[3] finds a better agreement between estimated[3] and inferred[2] abundances if interstellar matter is swept up rather than an old envelope (as would be the case if the exploding star were single).

The spun up neutron star in our model would move with a velocity equal to the centre of mass velocity the progenitor binary had acquired at the time of the formation of the neutron star[1]. (In refs 16, 17 it was assumed that a type L pulsar moves in the orbital plane of the progenitor binary). In the light of the above discussion, the fact that the motion of the Crab pulsar is directed away from the I Gem association permits a more plausible explanation (see ref. 6). The progenitor of the Crab was a massive close binary in I Gem. The first supernova explosion did not disrupt the binary, rather imparted the centre of mass a velocity of about 125 km s^{-1}. In about the 3 Myr between the first and the second explosion, the binary covered a distance of ~380 pc—crossing the galactic plane—and appearing at the site of the explosion of 1054. (Note that in the model of Gott *et al.*[6], the Crab pulsar did not acquire any velocity as a result of the supernova explosion).

The earlier suggestion[17] that PSR0532 is a type D pulsar and the associated type L pulsar should still be embedded in Crab nebula appears to be less attractive because of the problem of the abundance of heavy elements discussed above.

A sensitive search for radio pulses from primordial black holes and distant supernovae

THERE are two mechanisms of current theoretical interest which might generate short (< 1 ms) radio pulses detectable at interstellar or even cosmological distances. In both cases the pulse is generated by the alteration of a magnetic field by an expanding conducting shell. The phenomenon might occur either as the expanding core of a supernova 'combs' the star's intrinsic dipole field[1,2], or as the shell of charged particles emitted in the explosion of a primordial black hole (PBH) excludes the surrounding magnetic field[3]. In the latter case, the resulting radio pulse would, with suitable particle physics[3,4], be much easier to detect than the γ-ray pulses that might also accompany the explosion[5]. The best published upper limit on the frequency of such γ-ray pulses is 4×10^{-2} events $\mathrm{pc}^{-3}\,\mathrm{yr}^{-1}$ (ref. 6). We present here the results of a radio frequency search for isolated pulses, with much higher sensitivity than achieved previously. No definitive pulses have been detected, and the implied limit on PBH explosions is 2×10^{-9} events $\mathrm{pc}^{-3}\,\mathrm{yr}^{-1}$.

The results of several radio pulse searches have already been summarised, both from the point of view of supernova energies[7] and from that of limits on the number of PBH explosions[8]. Table 1 expands a summarising table from ref. 7, and gives the parameters of the most sensitive and most fully documented previous searches. We have attempted to compute the derived parameters as uniformly as possible, with a minimum of assumptions about the nature of the unseen pulses. Figure 1 shows the relative limits on the rate of pulse-producing events provided by the various surveys, plotted as a function of observing frequency.

Most of the published pulse searches have been carried out with simple receiving equipment and antenna apertures of not more than a few square metres. To achieve a greatly improved sensitivity limit, we have re-analysed data from a pulsar survey[9] done at the Arecibo Observatory in 1973–74. At 430 MHz the Arecibo telescope has an effective aperture of over 40,000 m^2, and the pulsar survey made use of a special dispersion-compensating radiometer that permits a relatively broad total bandwidth to be used without losing sensitivity to impulsive signals. Relevant parameters of the Arecibo observations are summarised in Table 2.

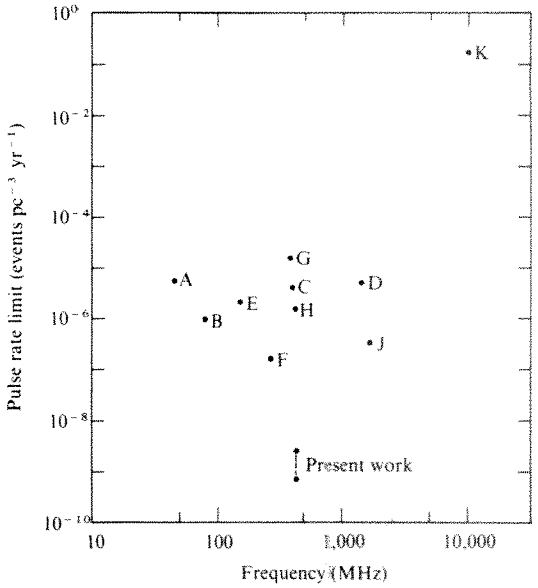

Fig. 1 Approximate limits on the rate of PBH explosions implied by the survey sensitivities listed in Table 1. The lower point plotted for the present work represents the limit as given in Table 1, computed as for the other surveys; the upper point is a firm, 8σ limit based on the data given in Table 2.

Dispersion compensation was done by a small computer that sampled each of the 32 receiver output channels every 16.7 ms and then recombined them with progressive delays to 'de-disperse' the signals. In the observations under discussion the dispersion range was 0–640 cm^{-3} pc (in steps of 20 cm^{-3} pc and with time resolution of 16.7 ms) and 0–1,280 cm^{-3} pc (steps of 40 cm^{-3} pc, time resolution of 33.3 ms). The de-dispersed data were arranged in blocks of 8,192 samples (4,096 for the high-dispersion range), and for each block a two-dimensional histogram was printed showing the distribution of detected, de-dispersed signal amplitudes, as a function of dispersion measure. The observed frequency distributions were indistinguishable from a gaussian curve over the range of amplitudes for which adequate statistics were available (±5 standard deviations of the noise), and were also indistinguishable from those produced when a calibration noise source was inserted into the system.

About 12,000 blocks of data were searched for evidence of narrow pulses of well defined, non-zero dispersion measure.

Table 1 Sensitivity parameters for 11 radio pulse surveys

1 Survey	2 Frequency ν (MHz)	3 Bandwidth $\Delta\nu$ (MHz)	4 Integration time τ (s)	5 System temperature T_s (K)	6 Solid angle Ω (sr)	7 Observing time T (h)	8 Threshold sensitivity $U_{\mathrm{min}}(\mathrm{J\,m^{-2}\,Hz^{-1}})$	9 Maximum distance for PBH d_{max} (pc)	10 Rate of PBH events R ($\mathrm{pc^{-3}\,yr^{-1}}$)
A[11,7]	45	1	0.6	25,000	1	1,768	1.1×10^{-21}	140	$5+10^{-6}$
B[12,7]	80	1	0.6	5,000	1	1,100	1.2×10^{-22}	280	1×10^{-6}
C[13,7]	400	0.06	1.7×10^{-5}	200	3	100	1.4×10^{-22}	270	4×10^{-6}

F[16]	270	50×0.25	0.02	200	1	213	1.1×10^{-24}	900	1.6×10^{-7}
G[17]	380	3	0.5	500	0.086	232	4.7×10^{-24}	430	1.6×10^{-5}
H[18]	430	1.5	0.1	1,100	3.3×10^{-4}	33	3.2×10^{-26}	5300	1.6×10^{-6}
J[19]	1665	15	0.002	200	5.6×10^{-5}	28	6.6×10^{-28}	3.7×10^{4}	3×10^{-7}
K[20]	10,000	40	0.5	20,000	1.5×10^{-3}	1,700	6.2×10^{-22}	38	1.9×10^{-1}
Present work	430	2×32×0.25	0.017	175	6.6×10^{-6}	292	1.3×10^{-29}	2.6×10^{5}	7×10^{-10}

Data given in columns 2–7 were taken directly (or estimated) from the original references or from Meikle and Colgate[7]. The 6σ threshold sensitivities (column 8) were computed from the relationship $U_{\mathrm{min}}=6(2kT_s)\Delta tA^{-1}(\tau\Delta\nu)^{-1/2}$ where k is Boltzmann's constant, $A=\lambda^2/\Omega$ is the effective antenna aperture, Δt is the apparent pulse width expected at the receiver output, and the remaining quantities are defined in the table headings. For surveys A–D, Δt will be dominated by dispersion broadening for interesting dispersion measures; the quoted value of U_{min} assumes $\Delta t=8{,}280\,DM\,\Delta\nu\,\nu^{-3}$ for ν, $\Delta\nu$ in MHz and $DM=100\ \mathrm{cm}^{-3}$ pc. For the remaining surveys U_{min} is independent of dispersion measure because Δt is dominated by τ. We have not allowed for differences in antenna efficiencies or the threshold σ values, because few authors gave these. The entries may thus be in error by a factor ~2. Column 9 gives the maximum distance at which a PBH event of $E=10^{16}\ \mathrm{J\,Hz^{-1}}$ could be detected; for surveys A–D we assume a mean density of 0.03 cm^{-3} for the electrons causing dispersion along the line of sight. Finally, column 10 gives the corresponding upper limit on the rate of PBH events. For surveys A–D, $d_{\mathrm{max}}\propto E^{1/3}$ and $R\propto E^{-1}$, while for the others $d_{\mathrm{max}}\propto E^{1/2}$ and $R\propto E^{-3/2}$.

0028–0836/79/0277—0117$01.00

Blocks with broad, high intensity features at low dispersion measures were rejected as containing terrestrial interference. On all other blocks, all 'events' at or above 6σ were catalogued. The frequency of pulses at the 6σ level was consistent with that expected from random noise fluctuations.

No pulses were found at, or above, the 8σ level, but eight unusual features seen at about 7 times the r.m.s. noise should be mentioned. These events do not seem to be mere statistical fluctuations, and most were found at such high aparent dispersion measures and so isolated that a plausible source of interference is not apparent. However, as they were evenly distributed in dispersion measure, and none appeared at or above 8 times the r.m.s. noise, it seems unlikely that many of them could have been produced by isolated events spaced uniformly over the region surveyed. They are not due to normal pulsars, because the original data was examined for periodicity ($0.033 < P < 3.9$ s) by a computer program which could detect pulsars well below 6 times the r.m.s. noise, and some of them are clearly due to single events that lasted less than the integration time. The pulses might be due to irregular giant bursts from very faint pulsars, or to some completely unknown terrestrial or extraterrestrial cause. A decision on the source would require either vast amounts of observing time with a single Arecibo-sized antenna, or a shorter period with two Arecibo-sized telescopes operating simultaneously.

The sensitivities and pulse rates quoted in Table 1 are based on a 6σ detection threshold and on the assumption that the pulses being sought are shorter than the integration times of the surveys. This assumption seems valid as the pulses produced by the mechanism mentioned earlier are expected to be intrinsically shorter than 10^{-6} s, and broadening of the pulses by interstellar scintillation, if it is like that observed for pulsars[10], should not be a problem, at least out to $DM \approx 500\ \text{cm}^{-3}$ pc (the largest dispersion yet observed for pulsars).

To make a rough estimate of the upper limit on the rate of PBH explosions implied by these observations, we assume that every explosion releases nearly mc^2 of energy over a bandwidth of 1 GHz. With the assumptions introduced by Rees[3] and Blandford[4], and taking the mass of still-unexploded black holes to be $m_{\text{crit}} \approx 10^8$ kg, we find that the explosion releases energy density $E \approx 10^{16}\ \text{J Hz}^{-1}$ at frequencies near $\nu_c \approx 1$ GHz. If the detection threshold is U_{min}, such an outburst could be detected to a distance d_{max} given by

$$U_{\text{min}} = E/(4\pi d_{\text{max}}^2). \tag{1}$$

The volume V surveyed is then

$$V = 1/3\, d_{\text{max}}^3 \Omega \tag{2}$$

where Ω is, say, the solid angle of the area of sky surveyed to better than −3dB of the on-centre sensitivity. The limit on the rate is then taken to be $R = (VT)^{-1}$, these rates are plotted in Fig. 1. The reader is invited to multiply them by the factor appropriate to his favourite distribution and confidence level. Corrections for $E \neq 10^{16}\ \text{J Hz}^{-1}$ may also be applied.

One must be careful in comparing the rates thus obtained, as there are many hidden assumptions (besides the one that the particle physics is such that the phenomenon can occur at all): first, the spectrum of the hypothetical pulses has been asumed flat from over the frequency range covered by these surveys; this is not likely to be the case[4], but because the value of ν_c is uncertain by several orders of magnitude, it is not possible to make any useful corrections.

Second, the magnetic field strength at the sites of the explosions is assumed to be a few microgauss. This is likely to be an overestimate for survey J and the present work, where much of the volume searched was intergalactic. Again, useful corrections are not possible, because ν_c and the strength of the intergalactic field are unknown.

Finally, the PBH's are assumed to be uniformly distributed throughout space. If they are assumed to be correlated with galaxies (into which they might have fallen), or anticorrelated (they might rapidly accrete to masses $>m_{\text{crit}}$ inside galaxies) comparisons become much more difficult.

Table 2 Parameters of the Arecibo search

Frequency	430 MHz
Bandwidth	32×0.25 MHz
Polarisations	2 circular, summed
Integration time	0.0167 s
Effective aperture	$4 \times 10^4\ \text{m}^2$
System noise temperature	175° K
Regions searched	Aquila, Taurus
Interference-free search time*	292 h*
Threshold sensitivity* (8σ)	$3 \times 10^{-29}\ \text{J m}^{-2}\ \text{Hz}^{-1}$

* Values quoted are for the lower dispersion-measure range. The higher *DM* data blocks had threshold sensitivity $4 \times 10^{-29}\ \text{J m}^{-2}\ \text{Hz}^{-1}$ and were interference-free for 368 h.

Any further interpretation of the data in Tables 1 and 2 must await theoretical developments.

A wind driven shell model for the absorption line systems in QSOs

THE spectra of many QSOs are rich in narrow absorption lines. The still somewhat uncertain identifications suggest that the absorption is due to ions of ionisation potential <40 eV. If the ionisation is due to the radiation from a central source, then theoretical models[1–4] give gas temperatures of <~30,000 K. The absorption line systems are generally blueshifted with respect to the emission line redshift of the object. If these blueshifts are Doppler shifts then they correspond to velocities ranging from ~0.001 to 0.5 of c (the velocity of light)[5]. The interpretation of these differential redshifts has been controversial[5]. Opinion has polarised about two extreme hypotheses—that all the absorption is due to intervening galaxies (the intervening hypothesis) or that it all arises in the vicinity of the QSO (the intrinsic hypothesis). At present, apparently the only way of mapping the Universe at large distances is by observing QSOs. The weakness of current models for intrinsic absorption has lead many to suppose that all the absorption occurs in intervening galaxies. If true, this has profound implications for the structure of the Universe. In particular, it implies that in the early Universe, galaxies had extremely large haloes (perhaps as large as 0.5 Mpc (ref. 6). Furthermore, it suggests that there also existed, at high z, large clusters of galaxies with velocity dispersions much greater than those hitherto observed at small z

0028-0836/79/0277—0118$01.00

(refs 5, 7, 8). Because of the importance of these conclusions for galactic structure and evolution, it is obviously essential to determine what proportion, in fact, of the absorption systems are intrinsic to the QSOs. We present here an intrinsic model which seems to explain the essential features of many absorption systems. This is a crucial first step towards the eventual separation of the observations into intrinsic and intervening systems.

The parameters given directly by the observations are the column density, ionisation state, velocity and velocity dispersion. It is also possible to estimate indirectly the density of the absorbing material[9] and its distance from the central radiation source[9–11]. Although uncertain[12], these estimates suggest that the absorption takes place in thin, dense ($\sim$10–10^3 cm^{-3}) shells at distances of the order of kpc (ref. 5).

All previous attempts[13–15] to explain these systems as intrinsic have relied on expulsion of gas from a central object. The principal difficulty with such models is that they are unable to produce enough absorbing material at large enough distances from the source. They also cannot account for the apparently normal abundances observed.

It is now generally believed that QSOs are active nuclei of galaxies and it is therefore reasonable to suppose that the absorbing material consists of interstellar gas which has been swept up by winds emanating from QSOs. Such a model gains added credibility from detailed investigations of the physics of radiatively accelerated winds[15,16] which show that it is inevitable that a significant fraction of the radiative energy output of a QSO is converted into kinetic energy of an outflowing wind[16].

If a QSO emits a wind with velocity V, and with a mass-loss rate $\dot{m}$, into a uniform stationary gas of density ρ_0, then the flow will be as shown in Fig. 1. This flow pattern is set up because V is much greater than the sound speed in the ambient gas. The validity of the hydrodynamic approximation is discussed elsewhere[17]. This situation is entirely analogous to the interaction of a high speed stellar wind with interstellar gas[18,19]. In the initial stages of the flow both the shocked ambient and wind material are far too hot either to cool or to give rise to absorption lines. In fact it can be demonstrated that the shocked QSO wind material behaves adiabatically over all time-scales of interest[17]. The effects of radiation pressure on the dynamics of the system can also be shown to be negligible during this phase[17]. During this completely adiabatic phase the position, r_s, of the outer shock can be described by the following similarity law:

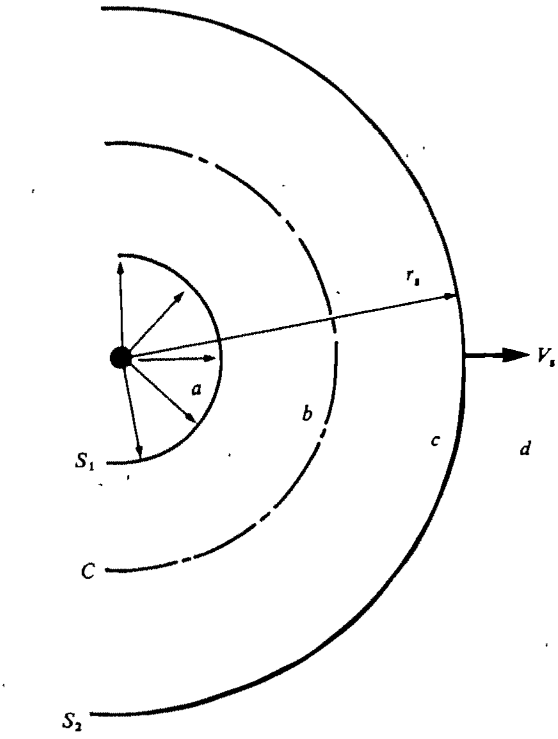

Fig. 1 Flow pattern of a QSO: *a*, the freely outflowing wind; *b*, the shocked wind; *c*, swept up ambient gas; *d*, undisturbed ambient gas. S_1 is an inwards facing shock in the wind, C is a contact discontinuity and S_2 is the outwards moving shock in the ambient gas.

$$r_s = \alpha \left[\frac{1}{2} \frac{\dot{m} V^2}{\rho_0} \right]^{1/5} t^{3/5} \qquad (1)$$

where α is a dimensionless constant which is found from computations[19] to be equal to 0.88. A similarity solution is valid because the characteristic length, $l = (\dot{m}/(V\rho_0))^{1/2}$, is small compared with the typical scale size of the flow for all reasonable values of the parameters. For the swept-up material to be visible in absorption, it must cool. Cooling sets in suddenly[19] when the radiative cooling rate exceeds the expansion cooling rate immediately behind the outer shock (S_2). This occurs at a time t_c when the shock has a radius r_c and velocity V_c given by[17]:

$$t_c \simeq 4.3 \times 10^6 \dot{E}_{46}^{3/11} n_0^{-8/11} \quad \text{yr} \qquad (2)$$

$$r_c \simeq 7.7 \dot{E}_{46}^{4/11} n_0^{-7/11} \quad \text{kpc} \qquad (3)$$

$$V_c \simeq 3.6 \times 10^{-3} \dot{E}_{46}^{1/11} n_0^{1/11} c \qquad (4)$$

In these equations the mechanical energy output rate, $\dot{E} = \frac{1}{2}\dot{m}V^2$ of the QSO is expressed in units of 10^{46} erg s^{-1}. In deriving these equations, the cooling rate has been taken to be $L = 1.68 \times 10^4 nT^{-1/2}$ erg g^{-1} s^{-1}. This is a reasonable approximation[20] for the temperature range, $5 \times 10^4 \text{ K} < T < 5 \times 10^7$ K, and is calculated on the assumption of normal solar abundances. This is the appropriate temperature range for the onset of cooling in all circumstances which have been considered[17]. (The above parameters are not, in fact, very sensitive to the numerical coefficient adopted in the cooling rate. If L is multiplied by a factor A, say, it can be shown that $t_c \sim A^{-5/11}$, $V_c \sim A^{2/11}$, and $r_c \sim A^{-3/11}$.)

Rather than attempting to present here a complete description[17] of results applicable to a wide variety of particular objects, we will now concentrate on the absorption system in the QSO 3C191. We do so because this object was not only the first QSO with identified absorption but is to date one of the very few QSOs which possesses an unambiguously identified set of absorption lines[5]. Studies of the spectra[11] place the absorption line system with a relative velocity of 0.0027 c at a distance of $\sim$10 kpc from the source, and estimate a column density of $N_{\text{HI}} \sim 3 \times 10^{19}$ cm^{-2} and a number density $\sim 10^3$ cm^{-3}. The observed visual luminosity, L_v, is 10^{47} erg s^{-1} (assuming $H_0 = 50$ and $q_0 = 0$).

We will suppose that the spectrum is flat ($\alpha \sim 1$) with a drop or cut off at about the He II ionisation limit. Theoretical studies[16] show that a value of $\dot{E} \sim 10^{45}$ erg s^{-1} is consistent with this spectrum and the observed visual luminosity. For n_0 we adopt the value of 1, but note that the results are rather insensitive to the actual choice of parameters. These values give $t_c = 2.3 \times 10^6$ yr, $r_c \simeq 3.3$ kpc, $V_c \simeq 0.0029\, c$. At this shock speed, the postshock temperature is $\sim 10^7$ K. The gas will now cool according to the cooling law above until it reaches a state of ionisation and thermal equilibrium with the radiation field. The equation of state is now[15,21]

$$P = R\rho y f(y) \qquad (5)$$

where

$$y = L_v/(4\pi r^2 \rho c^3) \qquad (6)$$

is the ionisation parameter[14,21], R is the gas constant, and $f(y) = T(y)/(\mu y)$. This state is critically dependent on the spectrum of the QSO[21]. For flat spectra $F(\nu) \sim \nu^{-\alpha}$ (with $\alpha \sim 1$) the equilibrium temperature is a few times 10^4 K. Calculations[21] of the photoionisation equilibrium show that over many orders of magnitude in y for most spectra, the gas is quasi-isothermal at either ~10^6 K (high ionisation) or ~10^4 K (medium ionisation to neutral). In these quasi-isothermal states a good approximation[15,21] for $f(y)$ is $f(y) \sim By^{-\beta}$, with $\beta \sim 1$, $B(10^6\text{ K}) \sim 6\times10^5$, $B(10^4\text{ K}) \sim 6\times10^3$. As the gas cools V will initially decrease, and an upper limit to the postshock pressure is

$$P_s = \frac{2}{\gamma+1}\rho_0 V_o^2 \tag{7}$$

Then the number density in the cool material is

$$n \leq n_0 \frac{V_o^2}{Ry_o f(y_o)} \tag{8}$$

where y_o is the equilibrium value of the ionisation parameter. Substituting equations (6) and (2) into equation (8), we obtain the implicit equation for y_o:

$$f(y_o) \leq 9.3\times10^{15}\, n_0^{-1/11} \dot{E}_{46}^{10/11} L_{\nu,46}^{-1} \tag{9}$$

$(L_{\nu,46} = L_\nu/10^{46})$

For the values of n_0, $\dot{E}$ and L_ν for 3C191, we find that $\log_{10} f(y_o) \simeq 14.1$. From Röser's[21] calculations we find $\log y_o \simeq -9.5$. For this spectrum, at y_o C IV and Si IV are the dominant ions. During the subsequent evolution[17] y decreases so that the gas becomes more neutral. From y_o and $f(y_o)$ we find that (equation (8)) $n \leq 2.3\times10^3$.

The shell thickness, Δr, is given by

$$\Delta r = \frac{1}{3}\frac{n_0}{n} r_s \tag{10}$$

so that $\Delta r/r \simeq 10^{-4} \ll 1$. (The importance of this small ratio is that it has always been supposed difficult to get such a small ratio in an intrinsic model.) The column density in neutral hydrogen, $N_{\text{HI}} \sim X(1-x)N_{\text{H}}$, where $N_{\text{H}} = n_0 r_o$ and $x = x(y)$ is the degree of ionisation of hydrogen, and X is the mass fraction of hydrogen. At y_o, $(1-x(y_o)) \sim 10^{-4}$, so that $N_{\text{HI}} \simeq 10^{18}\text{ cm}^{-2}$. Since y decreases, N_{HI} will increase.

All these values are in surprisingly good agreement with the observations in view of the crudity of this first model. This agreement can be shown to remain even when we consider non-uniform and non-spherically symmetric ambient density distributions[17].

Once a cool dense shell has formed, it will start to absorb momentum from the radiation field.

We do not discuss the further behaviour of the shell here in detail, because, in contrast with the formation of the shell, the flow depends strongly on the parameters. We show[17] that in the majority of cases, the shell accelerates due to the radiative driving and that often the acceleration is limited only by the total momentum content of the radiation field. If this happens, then it is unavoidable that the shell becomes subject to the radial instabilities discussed elsewhere[22], as well as non-radial instabilities[17]. The more effective the radiation driving, the higher the velocity and the more unstable is the system. Thus the mechanism seems capable of providing a natural explanation for the multiplicity of high velocity systems. In addition, if the shell does accelerate, then there will be some gas which cannot cool, and will be collisionally ionised, which might explain the apparently anomalous appearance of ions of high ionisation potential in otherwise relatively neutral systems.

We have also examined such important questions as the effects of varying the spectral distribution of the radiation field and of departures from spherical symmetry. These considerations place definite constraints on the characteristics of the radiation sources and on the gas distribution in galaxies in order that absorption line systems form by the mechanism discussed above. Note that the removal of gas by the wind will inevitably have important consequences for the further evolution of the galaxies.

Whereas we do not believe that this mechanism can explain all the absorption line systems of QSOs, our detailed exploration of its consequences[17] should provide a basis for distinguishing between intrinsic and intervening systems.

We thank the Max Planck Institute for Astrophysics for financial support and Professor R. Kippenhahn for his hospitality.

Measurement of forces between two mica surfaces in aqueous poly(ethylene oxide) solutions

WE have measured the forces between two curved mica surfaces immersed in a solution of 0.01% poly(ethylene oxide) (molecular weight 148,000) in 0.04 M $MgSO_4$ (a good solvent). The experimental technique allows the measureent of (1) forces as a function of surface separation; and (2) the refractive index of the medium between the surfaces[1,2]. The forces exhibited large irreversibilities as well as short-term and long-term time dependent effects, and we conclude that—for observation times less than a few hours—these interactions cannot be described in terms of an equilibrium force law without specifying the previous history of approach of the surfaces.

Figure 1 shows results obtained after 2 h equilibration. The arrows indicate the paths taken in measuring the forces ($A_1 \to B_1 \to C_1 \to A_2 \to \cdots$). Each compression–decompression cycle ($A_n \to B_n \to C_n$) took 5–15 min, during which the surfaces were approached to point B_n and then separated to a large distance, >300 nm, and after a time brought together again ($A_{n+1} \to B_{n+1} \to \cdots$). Three distinct force regimes were distinguished, which we label α, β and γ.

α-Regime: if the surfaces are kept well separated after a decompression for more than 10 min the initial repulsion on approach rises sharply and roughly exponentially, and its onset depends on the closest distance of previous approach (Fig. 1). However, if the surfaces are kept well separated for a few hours the forces always tend to the limiting force law (Fig. 1, dotted line). The repulsive forces in the α-regime extend over 15–30 nm, are reversible over short time periods (a few minutes), and have the same form irrespective of the onset separation. This regime may possibly be associated with the 'diffuse interpenetration' domain discussed by Napper[3]. (We also note that if the surfaces are approached within only 1 or 2 min after a decompression from a small separation the repulsion may be preceded by an attractive region. See Fig. 1, inset.)

β-Regime: on further approach the repulsion increases less rapidly and the force varies roughly linearly with distance, but closer in it rises more rapidly. The β-regime is highly unstable and irreversible: the force depends on the rate of approach, and if the surfaces are kept under a constant force they drift towards each other at 1–5 nm min^{-1}, though closer in the inward drift rate is lower. We have also observed that the surfaces can undergo sudden jumps towards each other, suggestive of the 'yield' characteristic of polymeric gels possessing a network structure undergoing partial collapse[4]. If the externally applied force is decreased in the β-regime the surfaces move out only very gradually or stick, indicating adhesion. The behaviour of the forces in the β-regime may be due to (1) slow adsorption (desorption) processes, including bridging, of tails during compression (decompression); (2) a slow reconformation of a polymeric network undergoing rearrangement of intertail crosslinks. The attractive forces measured during and soon after a decompression from a small separation also strongly suggests that significant bridging occurs.

γ-Regime: below ~5 nm, the repulsion increases very steeply and polymer now becomes forced out from between the surfaces, which ultimately come into molecular contact within ±0.05 nm of the original contact measured in $MgSO_4$ solution without polymer.

We have also measured the refractive index of the aqueous polymer medium between the surfaces at various separations. The refractive index n rises as the separation falls towards the γ-regime, thereby indicating that in the α- and β-regimes polymer is being compressed, though some extrusion may also be occurring. Typical values are: $n = 1.336 \pm 0.003$ at 45 nm, $n = 1.343 \pm 0.003$ at 11 nm. As for bulk polymer solution: $n = 1.334$, and for pure poly(ethylene oxide): $n = 1.454$, these results indicate that the number of adsorbed polymer chains per surface is $\sim 2 \times 10^{11}$ cm^{-2}—a similar value to that obtained for the equilibrium adsorption of high molecular weight poly(ethylene oxide) on silica[5].

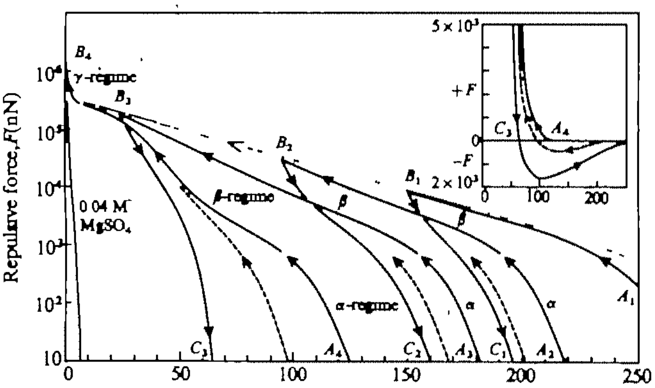

Fig. 1 Repulsive forces $+F$ measured between two crossed cylindrical surfaces of mica of radius ~1 cm as a function of separation D in 0.01% poly(ethylene oxide) in 0.04 M $MgSO_4$ at 21 °C. The force measured before addition of poly(ethylene oxide) is shown on the extreme left and corresponds to pure double-layer repulsion and van der Waals attraction[2,8]. The limiting force with poly(ethylene oxide) (dotted line) is attained a few hours after addition of polymer (for an approach rate of ~10 nm min^{-1}). After compression ($A_n \rightarrow B_n$) and decompression ($B_n \rightarrow C_n$), the subsequent compression forces measured ~1 min later are shown as dashed curves, while those measured 10–20 min later are shifted farther out ($A_{n+1} \rightarrow B_{n+1}$). The inset shows detail on a linear plot of the decompression ($B_3 \rightarrow C_3$) and subsequent compressions ($A_4 \rightarrow B_4$) measured 1 and 15 min, respectively, after decompression C_3.

The magnitude of the forces was different when different micas were used, probably reflecting the different adsorption capacity of poly(ethylene oxide) on different mica surfaces. However, the qualitative features discussed here were always the same, and forces were always measured at distances many times $\langle r^2 \rangle^{1/2}$ (~30 nm) of the poly(ethylene oxide), qualitatively similar to recent results obtained with poly(vinyl acetate)[6,7].

Our results indicate (1) the existence of a dilute long-range polymer layer forming on mica surfaces, probably possessing gel-like properties; (2) that even though the forces may be monotonically repulsive on approach, once significant overlap occurs there is sticking, probably through polymer bridging, resulting in effective adhesion; and (3) as the rate of segmental rearrangement towards equilibrium is very slow (>1 h) the effective forces between colloidal particles with adsorbed olymers of high molecular weight may often be determned by non-equilibrium relaxation mechanisms.

We thank D. Napper and R. Feigin for supplying and characterising the poly(ethylene oxide).

Recent trends in the $^{13}C/^{12}C$ ratio of atmospheric carbon dioxide

THE $^{13}C/^{12}C$ ratio of atmospheric carbon dioxide has decreased by approximately 0.6‰ over 22 yr according to new direct measurements reported here. Our results offer a way of establishing whether $^{13}C/^{12}C$ ratios of tree rings[1–6] are representative of atmospheric $^{13}CO_2$ variations. We have carried out both isotopic (at Groningen) and concentration (at La Jolla) measurements of atmospheric CO_2 on air samples obtained during 1977 and 1978 at three widely spaced locations: La Jolla, California (33°N, 117°W), Fanning Island (4°N, 159°W) and the South Pole. Sampling, instrumental, and analytical procedures closely matched a similar study carried out 22 yr earlier by Keeling[7,8].

The new isotopic measurements are plotted in Fig. 1 as the per mil variation, $\delta^{13}C$, of the $^{13}C/^{12}C$ ratio from the historic standard PDB. Also plotted are isotopic data for 1955 and 1956 for those sites and times of day of the original study having minimal local disturbance to the CO_2 concentration from vegetation. Published 1955–56 $\delta^{13}C$ values have been recomputed from the original mass spectrometer mass ratios, 45/44 and 46/44, to be consistent with the computational methods used for the 1977–78 data. Corrections for valve mixing and ^{17}O

0028-0836/79/0277—0121$01 00

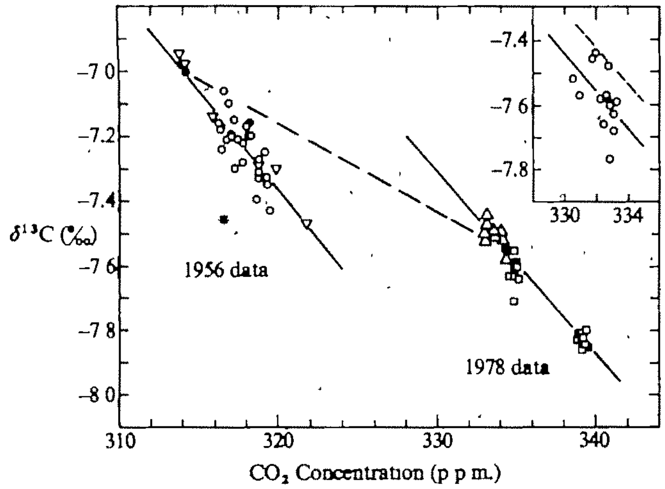

Fig. 1 Change in the relation between carbon isotopic ratio $\delta^{13}C$, and concentration of atmospheric CO$_2$ over 22 yr. Mean change is shown as a dashed line. Locations as follows: ○, Inyo Mountains; *, Inyo sample omitted in computing equation (2), ▽, three west coast United States sites shown for comparison (only samples collected nearest noontime are plotted), Olympic Beach[7], Yosemite National Park[8], Organ Pipe National Monument[8]; △, Fanning Island; □, La Jolla, California. Solid lines show mixing relations for 1956 and 1978 as given by equations (2) and (1), respectively. ●, denote inferred Northern Hemispheric means for 1956 and 1978. Inset: relationship of $\delta^{13}C$ to concentration for the South Pole. Solid line shows mixing relation assuming same slope as Northern Hemisphere (shown dashed.)

follow prescribed methods[9]. The new measurements are calibrated against NBS-20 and a set of organic standards in use since 1963 (ref. 10), whereas the 1955–56 measurements are against PDB itself and two other carbonate standards previously calibrated against PDB. Recomputation has lowered the 1955–56 $\delta^{13}C$ values by 0.09 to 0.10‰. Details of this recomputation, and instrumental and analytical details of the new measurements, will be published elsewhere.

The calibration accuracy of the 1955–56 data is estimated to be within ±0.13‰; that of the new data ±0.05‰.

As seen in Fig. 1, the 1977–78 Northern Hemisphere samples irrespective of latitude closely follow a single mixing equation[7] (in per mil):

$$\delta = -26.54 + 6346.98/\mu \qquad (1)$$

where the first term denotes the $\delta^{13}C$ of CO$_2$ added or subtracted from the sampled air by either fossil fuel combustion or plant activity (which cannot be distinguished); μ is the CO$_2$ concentration in p.p.m. of dry air. We adopt a provisional estimate of the seasonally adjusted concentration for Mauna Loa Observatory (unpublished) as representative of the Northern Hemisphere for 1 January 1978; thus $\mu_{78} = 334.2$ p.p.m. It follows from equation (1) that $\delta_{78} = -7.55$‰. A similar analysis for the Southern Hemisphere (South Pole data) yields $\delta_{78} = -7.59$‰ for $\mu_{78} = 332.6$ p.p.m. Thus no appreciable mean isotopic gradient appears to exist between hemispheres in spite of a small gradient in the seasonally adjusted concentration.

For 1955–56 the Inyo Mountain series (37°N, 118°W) of March 1956, are the most extensive set of data for a single location. These data obey the mixing equation:

$$\delta = -26.97 + 6271.63/\mu \qquad (2)$$

To obtain a representative value of μ we extrapolated backwards from early 1958 when the first precise concentration measurements were obtained at Mauna Loa Observatory[11] on the assumption that the CO$_2$ varied in proportion to the known input from fossil fuel between 1956 and 1978. For January 1, 1956 we find $\mu_{56} = 314.1$ p.p.m. It follows from equation (2) that $\delta_{56} = -7.01$‰.

The above isotopic ratios for both 1956 and 1978 are influenced by atmospheric N$_2$O which is included in the sample gas analysed by the mass spectrometer[12]. To correct for this we assumed a present N$_2$O concentration of 0.30 p.p.m. and a 1.5% increase in N$_2$O per decade[13]. The correction is +0.32‰ in 1956 and +0.31‰ in 1978.

We find that the composition of atmospheric CO$_2$ over the Northern Hemisphere has changed from 1956 to 1978 as follows:

CO$_2$ concentration (μ): 314.1 to 334.2 p.p.m.

carbon-13 ratio (δ): −6.69 to −7.24‰

For the Southern Hemisphere no isotopic data exist for 1956. Concentration data since 1958 (ref. 14) and the present isotopic data indicate, however, that differences between both hemispheres cannot be large compared to hemispheric changes in 22 yr. We therefore regard the Northern Hemisphere data as being close to global averages.

The observed decrease in $\delta^{13}C$ over 22 yr agrees to the stated accuracy with predictions of the effect of fossil fuel combustion on the carbon cycle[15] based on two recently published geochemical models[16,17]. In summary, these models yield almost identical predictions if the land biosphere is assumed to respond to the recent atmospheric CO$_2$ rise[17] such that the observed increase (20.1 p.p.m. or 43 Gton C) is satisfied. When the isotopic fractionation factors (kinetic air to sea, 0.986; equilibrium air to sea, 1.009; air to biosphere, 0.982; air to fossil fuel, 0.980) are treated without mathematical approximation[18], the decrease in $\delta^{13}C$ is 0.44‰ for a fossil fuel CO$_2$ input of 79 Gtons (ref. 17 and unpublished data). This result assumes that the biosphere grew in 22 yr by 12 Gtons. The model predictions, however, are insensitive to biospheric growth which can even be assumed negative. For example, the models predict a change of 0.42‰ if the biosphere shrunk by 40 Gtons, attended by a much greater oceanic uptake of CO$_2$ than assumed in the first calculation (76 instead of 24 Gtons).

This circumstance suggests that a time record of atmospheric ^{13}CO$_2$ data cannot help decide the rate of biospheric growth or shrinkage during this 22 yr period of concentration measurements. Such a record may, nevertheless, be a valuable substitute before the time of reliable direct concentration measurements. Our results are offered as an aid in verifying tree ring studies which span both the past and recent periods.

We thank Alane Herron, John Jennings and Jaap Jongsma for assistance with the measurements and Robert Bacastow, Harmon Craig and Samual Epstein for critical discussions. This work was supported by the Climatic Dynamics Program of the NSF.

Effect of variable energy input on nitrogen fixation in instantaneous linear discharges

ATMOSPHERIC nitrogen oxides are a central issue in the photochemistry of the troposphere, stratosphere and urban atmosphere. The removal of nitrogen oxides by precipitation is a source of fixed nitrogen to the biosphere. Thus the nitrogen fixation rate by natural and anthropogenic discharges is of wide concern[1–8]. While it is generally assumed that P, the molecules of NO produced per joule of discharge, is independent of the input energy, the analysis reported here implies that P does vary with input energy. Thus care must be taken when extrapolating NO yields from small laboratory sparks to more energetic processes of potential geochemical significance. Although the calculations assume a cylindrical symmetry appropriate for a linear discharge, the results are consistent with equivalent calculations using spherical symmetry.

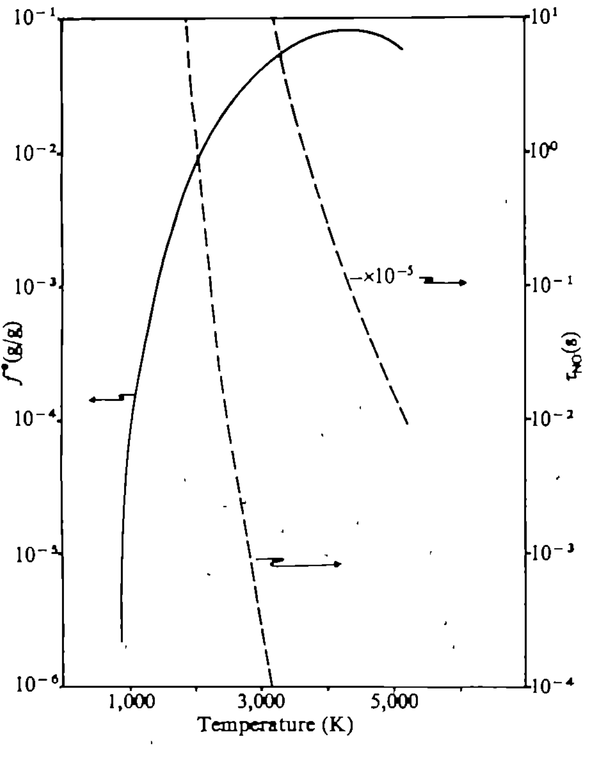

Fig. 1 The NO equilibrium mass mixing ratio, f°, represented by the solid line, and the NO chemical lifetime, τ_{NO}, represented by the dashed line, as a function of temperature, T. Thermochemical data from the JANAF tables[9] was used to determine f° from an initial mixture of 0.78 atm N_2, 0.21 atm O_2, 0.01 atm H_2O, 3.3×10^{-4} atm CO_2, and 1.5×10^{-6} atm CH_4, and ambient temperature of 288 K, and an assumed n_{M}, number density within the heated air, of 2.5×10^{19} molecules cm^{-3}. The equilibrium concentrations as a function of T were determined for N, N_2, NH_x ($x = 1, 2, 3$), NO, NO_2, O, O_2, O_3, H, H_2O, H_2, HCN, OH, HO_2, CO, CO_2, CH_x ($x = 1, 2, 3, 4$), N_2O and HNO. The rates of the reactions $NO + N \rightarrow N_2 + O$, $NO + O \rightarrow N + O_2$, and $NO + NO \rightarrow N_2O + O$ were used to determine τ_{NO} with kinetic data obtained from Baulch *et al.*[10] and Hampson and Garvin[11].

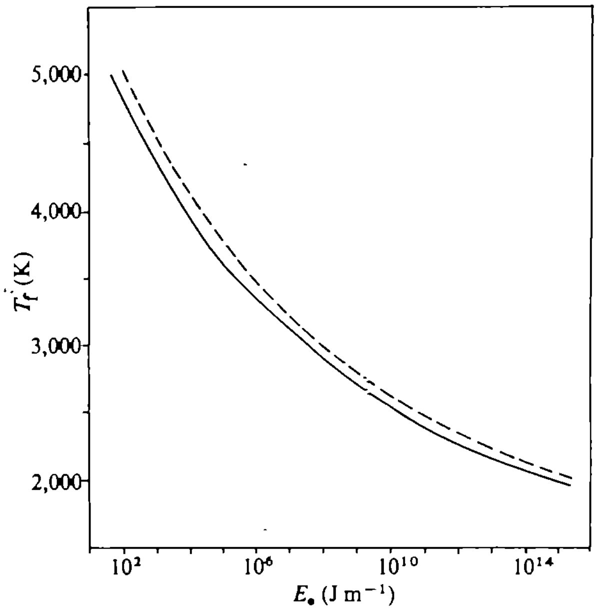

Fig. 2 The freeze-out temperature, T_{F}, as a function of discharge energy, E_0, as determined from equation (8). The solid line is for $\gamma = 1.4$ and the dashed line is for $\gamma = 1.25$.

As identified by Zel'dovich[1,2], N_2 and O_2 are converted to NO by high temperature chemical reactions occurring in the shock-heated air surrounding the discharge. Figure 1 shows f°, the equilibrium NO mass mixing ratio, and τ_{NO}, the NO chemical lifetime, as a function of temperature, T, for an initial mixture of air at 1 atm and 288 K. Defining n_{M} as the number density of the heated air, τ_{NO} is accurately represented by

$$\tau_{\mathrm{NO}} = \frac{1.55\times10^{-2}\exp(53{,}942/T)}{n_{\mathrm{M}}^{1/2}} \qquad (1)$$

(Calculations indicate that for the region of interest n_{M} is 1–10 times the ambient number density. As n_{M} increases, f° slowly decreases.)

If a parcel of air is heated to $T \geq 4{,}000$K and cooled at a rate characterised by a cooling time, $\tau_{\mathrm{T}}(T)$ NO will remain in equilibrium until $T = T_{\mathrm{F}}$, the 'freeze-out' temperature, where

$$\frac{\tau_{\mathrm{T}}(T)}{\tau_{\mathrm{NO}}(T)} \begin{cases} > 1 \text{ for } T > T_{\mathrm{F}} \\ = 1 \text{ for } T = T_{\mathrm{F}} \\ < 1 \text{ for } T < T_{\mathrm{F}} \end{cases} \qquad (2)$$

For $T < T_{\mathrm{F}}$, NO is too long-lived to adjust to the decreasing temperature and NO is frozen at $f^\circ(T_{\mathrm{F}})$. The NO yield is approximated by

$$P = \frac{M(T_{\mathrm{F}}, E_0) f^\circ(T_{\mathrm{F}})}{E_0} \, \frac{6.02\times10^{23}}{30\times10^{-3}} \quad (\text{molecules J}^{-1}) \qquad (3)$$

where M is the mass (kg m^{-1}) of air heated above T_{F} and E_0 is the input energy (J m^{-1}).

To evaluate τ_{T} and M we adopt the numerical-difference equations derived by Lin[12] which simulate a strong shock produced by an instantaneous linear discharge. While these equations do not directly consider translational, rotational, vibrational and chemical modes of energy transfer, by assuming specific heat ratios, γ, of 1.4 and 1.25, these effects should be adequately bounded[13]. For an ambient pressure, p_0, of 1,013

0028–0836/79/0277—0123$01 00

nsity, ρ_0, of 1.228 kg m^{-3}, T^1, the shock front e, is

$$T^1 = A(\gamma)\frac{E_0^{1/2}}{t} \quad \text{(K)} \tag{4}$$

where t is the time in seconds after the discharge and

$$A(\gamma) = \begin{cases} 1.11 \times 10^{-4} & \text{for } \gamma = 1.4 \\ 6.18 \times 10^{-5} & \text{for } \gamma = 1.25 \end{cases} \tag{5}$$

Following Zel'dovich and Raizer[1], we define τ_T at $T^1 = T_F$ as

$$\tau_T(T_F) = \left(\frac{1}{T^1}\frac{dT^1}{dt}\right)^{-1}\Bigg|_{T^1 = T_F} \tag{6}$$

from equation (4)

$$\tau_T(T_F) = \frac{AE_0^{1/2}}{T_F} \tag{7}$$

Thus τ_T increases as E_0 increases, or the cooling rate decreases as the surface-to-volume ratio decreases.

Combining equations (1), (2) and (7), for $n_M = 2.5 \times 10^{19}$ cm^{-3},

$$E_0 = \left[\frac{3.0957 \times 10^{-12}}{A} T_F \exp(53942/T_F)\right]^2 \quad (\text{J m}^{-1}) \tag{8}$$

Figure 2 illustrates the resulting inverse relationship between T_F and E_0 for $\gamma = 1.4$ and 1.25. While $T_F \sim 2{,}000$ K for $E_0 \sim 10^{14}$–10^{15} J m^{-1}, for lower energies $T_F > 2{,}000$ K. These results contradict previously held assumptions that $T_F \sim 2{,}000$ K, independent of E_0, and, as outlined below, implies that P varies with E_0.

From Lin's[12] equations,

$$M(T_F, E_0) = \pi R^2(T_F, E_0)\rho_0 = \frac{C(\gamma)E_0}{T_F} \quad (\text{kg m}^{-1}) \tag{9}$$

where R is the shock front radius and

$$C(\gamma) = \begin{cases} 3.95 \times 10^{-4} & \text{for } \gamma = 1.4 \\ 1.71 \times 10^{-4} & \text{for } \gamma = 1.25 \end{cases} \tag{10}$$

Substituting in equation (3)

$$P = C(\gamma)\frac{f_0(T_F)}{T_F}\frac{6.02 \times 10^{23}}{30 \times 10^{-3}} \quad (\text{molecules J}^{-1}) \tag{11}$$

The dependence on E_0 is caused by the variation of T_F with E_0. Because $R^2 \propto 1/\rho_0$, P is not directly dependent on ρ_0 or p_0; the variation of τ_T and f^0 with ambient conditions results in only a weak dependence of P on p_0 and ρ_0.

Figure 3 depicts P for $\gamma = 1.4$ and 1.25 as well as some laboratory results[7,14,15], which are consistent with the variations predicted here. The equivalent NO yields for megaton point explosions determined by previous investigators[3–6] which are included in Fig. 3 are also consistent with the present results.

As E_0 decreases from 10^{15} to 10^4 J m^{-1}, f^0/T_F increases and thus P increases. For $E_0 < 10^4$ J m^{-1}, however, $T_F > 4{,}000$ K, f^0 maximises and then decreases, and thus P also decreases. Over the range 10^1–10^{16} J m^{-1}, P varies by a factor of about 9 with a maximum near 10^4 J m^{-1}. Decreasing γ from 1.4 to 1.25, reflecting an increase in heat capacity, causes a 50% decrease in P.

In addition to the above dimensional calculations, fully time-dependent calculations were carried out, similar to those of Goldsmith *et al.*[5], to confirm the behaviour of P. Using Lin's[12] equations, the temperature and density histories of 11 mass shells (of 10^{-5}, 10^{-3}, 2×10^3, and 2×10^7 kg m^{-1} for $E_0 = 10^3$, 10^5, 10^{11}, and 10^{15} J m^{-1}, respectively) extending radially outward were obtained. These parameters as a function of time were coupled to an $N_2/O_2/NO$ chemical scheme[5,10,11] to determine the NO production within each shell. The results of these kinetic calculations are also indicated in Fig. 3. Because the kinetic calculations included the enhanced densities of the shocked air while the dimensional calculations assumed $n_M = 2.5 \times 10^{19}$ cm^{-3}, the yields from the former method are somewhat lower than those from the dimensional approach. The finding from both calculations that P may vary by as much as an order of magnitude over the range of input energies is of potential geochemical significance. An illustrative example is presented below.

To estimate the fixation rate by atmospheric lightning, Chameides *et al.*[7] adopted a P of $(6 \pm 1) \times 10^{16}$ molecules J^{-1} on the basis of 10^1 J m^{-1} spark experiments and simple calculations assuming $T_F \sim 2{,}000$ K. However, if a lightning stroke dissipates about 10^5 J m^{-1} (ref. 16), a value of $(8$–$17) \times 10^{16}$ molecules J^{-1} may be more appropriate, assuming that the highly idealised shock wave model used here adequately simulates the cooling of air around a lightning discharge. Taking 1.6×10^{-7} J cm^{-2} s^{-1} (ref. 7) as the total energy dissipated by lightning, we obtain a global NO production rate of $(1$–$2.5) \times 10^{10}$ NO molecules cm^{-2} s^{-1} or $(35$–$90) \times 10^{12}$ g N yr^{-1}. This may be an overestimation if a large portion of the stroke energy is consumed by the leader or if multiple-stroke flashes do not additively increase the NO yield. For comparison, it is estimated that ~ 20–30×10^{12} g N yr^{-1} are produced by anthropogenic activities[17,18]. As nitrogen oxides are removed from the atmosphere at a rate of $\sim 90 \times 10^{12}$ g N yr^{-1}[7,19,20], it is likely that lightning and combustion are the major sources of atmospheric nitrogen oxides[18,21], both processes involving the conversion of N_2 and O_2 to NO by high temperature chemical reactions.

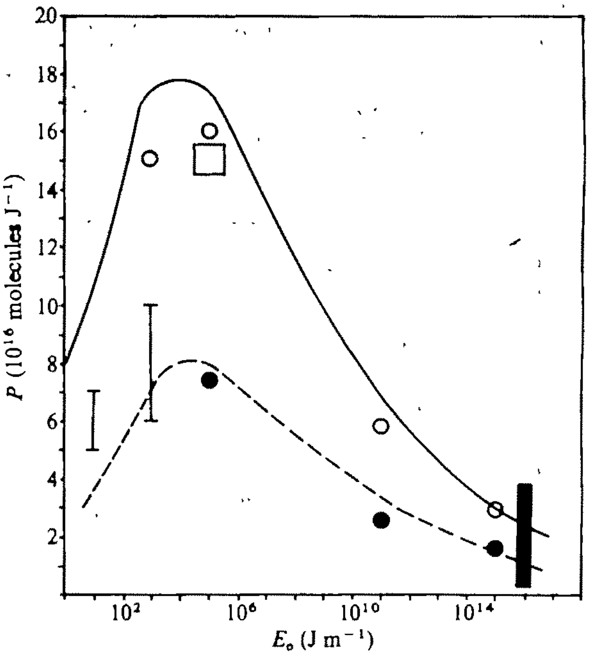

Fig. 3 The yield of NO, P, as a function of discharge energy, E_0. The solid line is for $\gamma = 1.4$ and the dashed line is for $\gamma = 1.25$. The results of the fully time-dependent calculations for $\gamma = 1.4$ (○) and $\gamma = 1.25$ (●), are given. The vertical lines depict the experimental findings of Chameides *et al.*[7] and the square the results of the experiments of Zipf and Dubin[14,15]. The vertical rectangle indicates the equivalent results obtained by previous investigators using spherical geometry for explosions in the megaton range[3–6].

Black Sea sterol—a molecular fossil for dinoflagellate blooms

A PECULIAR sterol has been found in recent sedimentary environments which we eventually found was identical with the Black Sea sterol. This sterol was first mentioned among the extractable sterols from the Black Sea sapropel layer as the dominant component[1]. The concentration of this sterol in these rare sediments seemed high enough for us to isolate and purify the object to determine its molecular structure and evaluate its significance. We have isolated and analysed the sterol fractions from the Black Sea sapropel (by techniques to be described elsewhere), but here only elucidate the molecular structure of the Black Sea sterol and discuss its significance.

The sediment investigated, which was deposited during the rise of the oxic–anoxic (H_2S) interface after the last glaciation in the Black Sea (7,000–3,000 yr BP), has an organic matter content up to 50% and is composed of numerous membranous structures[2]. During this period the surface water of the Black Sea gradually changed from fresh water to marine conditions. This was accompanied by a changing phytoplankton population from fresh water diatoms and dinoflagellates to marine coccolithophores in the period after 3,000 yr BP (ref. 2). The oceanographic conditions in the brackish water period together with special pathways of organic matter degradation, transformation and preservation in the gradually more anoxic deep water, must have led to the deposition of the unusually organic rich sediment. The abundance of dinoflagellate cysts in the sediment points to an important role of these algae in the brackish water period, which is understandable considering the wide salinity tolerance of dinoflagellates[3]. We feel that the occurrence of the Black Sea sterol could be related to the postulated abundance of dinoflagellates in the surface waters during the period 7,000–3,000 yr BP. The knowledge of the exact structure of this peculiar and abundant sterol in the sediment must give clues to its biosynthetic origin and subsequently to the origin of the sedimentary organic matter. The sediment investigated was sampled by gravity corer in the Western abyssal basin of the Black Sea (41°39′ N, 30°44′ E, −2,150 m). The core (covered core length 118 cm) consisted of a white top layer (0–27 cm), a dark green microlaminated layer (27–71 cm) similar in appearance to the Unit 2 sediment of Ross and Degens[4], and clayish sediments (71–118 cm). The section from 27 to 71 cm was received frozen for analysis. The sediment was homogenised in a Waring blender and divided into portions of 250 g. Total sterols were isolated from the extract of such a portion, obtained after saponification of the wet sediment by ethanolic KOH, followed by digitonin precipitation for isolation of the 3β-sterols. The digitonin precipitation procedure was carried out by addition of an excess amount of a 1% digitonin solution in 90% ethanol to the extract dissolved in C_2H_5OH–CH_2Cl_2 (3 : 1, v/v).

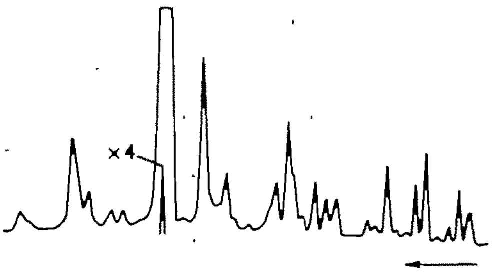

Fig. 1 Capillary gas chromatogram of the total sterols isolated from the Black Sea sapropel layer.

After stirring for two hours at room temperature, the mixture was centrifuged and the precipitate washed thoroughly with ethanol. The precipitate was refluxed in pyridine for 30 min. Digitonin was precipitated from the reaction mixture by addition of diethyl ether. The diethyl ether–pyridine solution was treated with 2 M HCl and the ether layer, containing the freed 3β-sterols, was dried over anhydrous Na_2SO_4. The isolated sterol fraction was transformed into the corresponding trimethylsilylethers by BSA (bistrimethylsilylacetamide, Pierce). Gas chromatographic separation was achieved on a Perkin Elmer 990 instrument, equipped with a 25 m glass capillary column (i.d. 0.25 mm) coated with OV 101. The temperature was programmed from 140 to 280 °C at a rate of 4 °C min^{-1}. Helium was used as carrier gas. Figure 1 shows the appropriate part of the capillary gas–liquid chromatography trace of the sterol fraction. The major peak in this gas chromatogram, previously designated as 'Black Sea sterol', was the subject of a detailed structural analysis. Figure 2 shows the mass spectrum of the Black Sea sterol trimethylsilylether derivative, which was obtained by gas chromatography/mass spectrometry on a Hitachi MS 52 instrument equipped with a 42-m glass SCOT column (i.d. 0.75 mm) coated with OV 101.

The molecular ion *m/e* 500 points to a C_{30} steroidal alcohol with one double bond equivalent. The fragment ions *m/e* 229, *m/e* 231, *m/e* 269 and *m/e* 271 indicate a ring saturated steroid skeleton with one 4-methyl group[5]. The mass spectrum is identical to the mass spectrum of the trimethylsilylether derivative of Dinosterol (4α-methyl-5α(*H*)-Δ^{22}-23,24-dimethyl-cholestan-3β-ol)[6].

Further evidence for the possible similarity between the Black Sea sterol and dinosterol was obtained by comparative studies using ^{1}H NMR and high-resolution gas chromatography.

For that purpose the crude Black Sea sterol was purified further by preparative thin layer chromatography on silica gel with $CHCl_3$–CH_3OH (99 : 1, v/v) as eluent. Crystallisation of the purified sterol yielded 200 μg of needles with a melting point of 220–220.5 °C. The melting point of dinosterol has been reported[7] to be 220–222 °C.

The ^{1}H NMR was measured on a Varian CFT-20 spectrometer in $CDCl_3$. The spectrum of the Black Sea sterol was found to be identical with the one of dinosterol showing a vinyl proton at δ4.96 (1H, q, $J = 1.1$, 10 Hz) and vinylic methyl protons at δ1.59 ($J = 1.1$)[6,7]. High resolution gas chromatography was performed on a Perkin Elmer 990 equipped with glass capillary column on two different polymers (OV-101 and Carbowax high polymer). The retention times of the silylated derivatives of both sterols were identical on co-injection.

These data demonstrate that the Black Sea sterol possesses a structure identical to that of the dinosterol, being 4α-methyl-5α(*H*)-Δ^{22}-23,24-dimethyl-cholesten-3β-ol. As dinosterol has

0028-0836/79/0277–0125$01.00

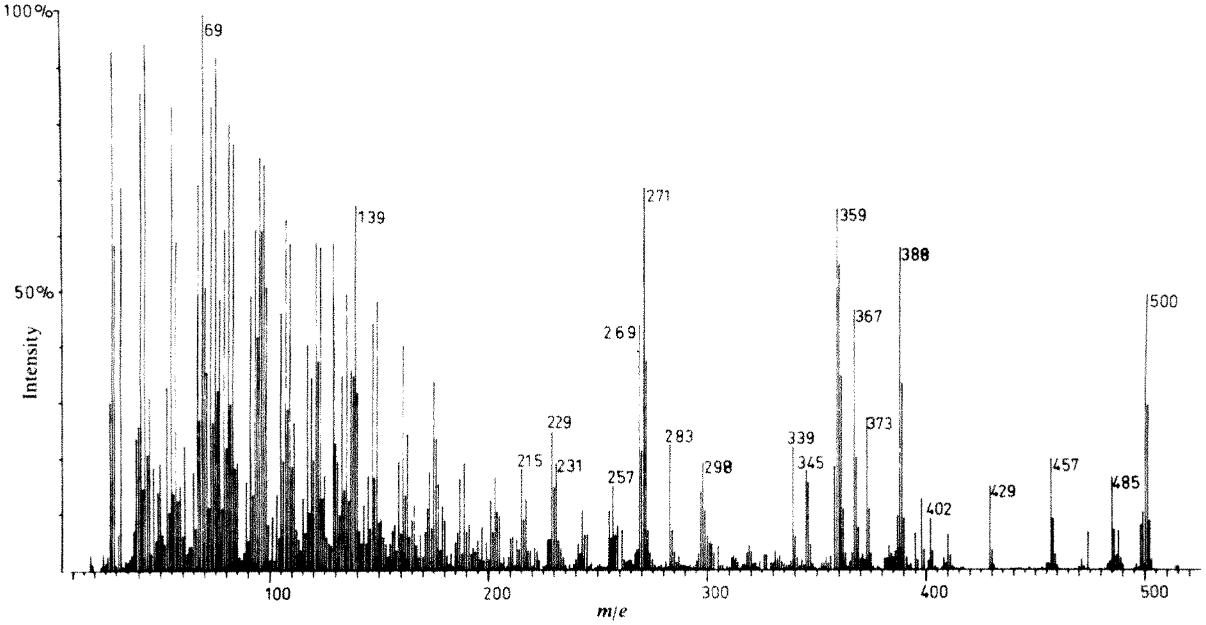

Fig. 2 Mass spectrum of the Black Sea sterol obtained by capillary GC–MS of the silylated sterol fraction. The Δ^{22}-23,24-dimethyl unit in the side chain can be recognised in the mass spectrum by m^{+}-71 and m^{+}-71–90. A fragmentation process is postulated in view of literature data[15]:

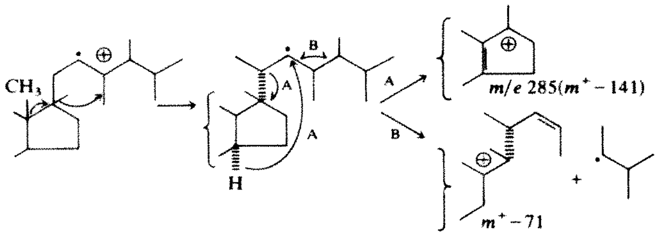

previously been encountered as the major sterol in some dinoflagellates only[6], we assume that the abundance of this sterol in the extract of the sapropel layer of the Black Sea sediment reflects a relatively large contribution of dinoflagellate organic matter to this sediment. The remarkable richness in organic matter of the sapropel layer compared with the present marine deposits (Unit 1)[4] suggests periodic blooming of these algae in the brackish water ecosystem as the possible mechanism for organic matter supply, as otherwise similar conditions of preservation and allochthonous sediment influx for both sediment types exist.

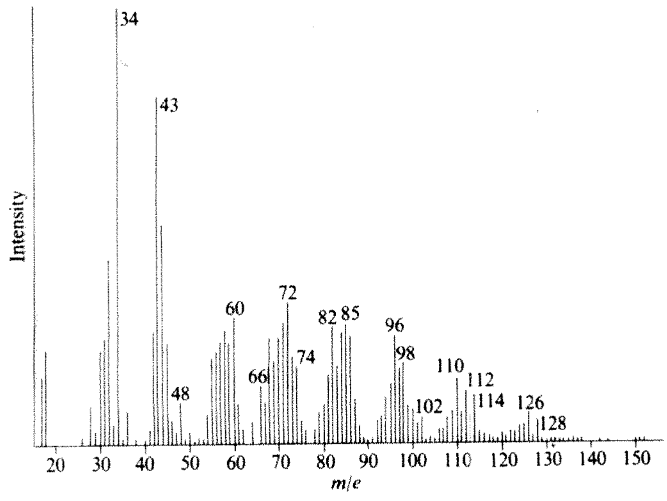

Fig. 3 Curie-point pyrolysis mass spectrum of homogenised Black Sea sapropel. Pyrolysis temperature: 610 °C; ionisation voltage: 14 eV.

To establish the relative contribution of organic matter from different sources, an analysis of the bulk composition of the organic matter by Curie point mass spectrometry was undertaken[8]. This relatively new technique has demonstrated its merits in the analysis of bacteria, fungal cell walls, humic substances and kerogen[9–12].

The pyrolysis mass spectrum of the sapropel (Fig. 3) shows the abundant occurrence of pyrolytic fragments typical of polysaccharides such as *m/e* 32, 60, 72, 74, 82, 85, 96, 98, 102, 110, 112, 114, 126 and 128; and to some extent aminosugar polymers such as *m/e* 95, 97, 109, 125, 137, 151.

Pyrolytic fragments typical of proteins such as *m/e* 17, 34, 48, 67, 92, 94, 108, 117, 131, and lignin such as *m/e* 94, 108, 124, 138, 150, 152, 164 are very low or even absent[10,11].

The pyrolysis fragments *m/e* 17, 34, 36, 38 and 48 are due to compounds such as ammonia, seasalt (HCl) and sulphur compounds (H_2S and CH_3SH). The intense H_2S peak is usually encountered in sediments with active or fossil sulphur-reducing activity.

As the thecal plates of dinoflagellates are mainly composed of polysaccharides[13], we think that the bulk of the Black Sea sapropel is mainly built up from dinoflagellate remains.

Contributions of bacterial organic matter previously based on the analysis of the sedimentary fatty acids[14], is now substantiated by the presence of aminosugar polymers, which make up the cell walls of bacteria.

The Black Sea sapropel unit therefore should be considered as a dinoflagellate ooze, partly reworked by anaerobic bacteria.

We thank Drs A. L. Burlingame and H. L. C. Meuzelaar for mass spectrometric facilities, also the Koninklijke Shell Exploratie en Produktie Laboratorium (Rijswijk, Z-H) (Shell) for donation of the Black Sea sample.

Elimination of natural scrapie in sheep by sire genotype selection

SCRAPIE, a subacute neuromuscular disease of middle-aged sheep, has been attributed variously to an infection or to heredity[1,2]. The clinical disorder follows progressive symmetrical decay of neurones in localised brain sites, notably the hypothalamo–neurophysial and olivo-pontocerebellar 'systems' (ref. 3), associated with a terminal axon dystrophy[4–9]. An artificially transmissible spongiform encephalopathic agent (TSEPA), or 'slow virus', to which many attribute the disease[10,11], is commonly present in diseased animals but its aetiological role remains unclear. Based on the clinical manifestation of natural scrapie, I have proposed that the disease is controlled by an autosomal recessive gene[1,2,12]. This hypothesis allowed identification of the three presumptive genotypes (*ss*, *sS*, *SS*), and precise prediction of attack rates[13,14], amenable to quantitative experimental verification[15]. The evidence summarised here, which has been compiled since 1958, provides strong support for my hypothesis.

The data have been collected from stud sheep flocks, each of 50–300 ewes, of 11 breeds in England and Scotland[12,16]; a 25-yr continuous record of one breeder group of 15–20 flocks with 2,500 ewes provides the principal data, which are supplemented by records of my own experimental flock of 250. Only 35–40% of the females and 1–2% of the males in the flocks have been kept past the age of 1½ yr. Half of these survive to 4½ yr and a few to 10 yr. Ten other breeder groups with 200 flocks have provided data over shorter periods, to give records on some 40,000 individuals.

The diagnosis of scrapie was based on (1) clinical signs[2], (2) the family and clan health history[2], (3) autopsy after euthanasia[3], (4) 'blind' histopathological assessment by light microscopy[3,12] with occasional use of electron microscopy[4–6] and immunohistochemistry[7–9] and (5) occasional assay for the TSEPA. Of about 3,000 affected animals, I have observed 2,100 and autopsied 1,900, of which 1,040 were examined histopathologically, with only two disagreements with the other criteria.

As, in our population, 85–90% of all cases of scrapie were recognisable clinically by 4½ yr of age[2], I took this as the minimum age for classification designated as follows. (1) 'Black': affected, or if unaffected, with both parents affected, that is, of presumptive homozygous recessive *ss* genotype; (2) 'grey': unaffected, but with one parent affected or with affected progeny, that is, of presumed heterozygous recessive *sS* genotype; (3) 'white': unaffected, with neither parent affected and with no affected progeny, that is, of probable homozygous dominant *SS* genotype, although a proportion, the progeny of grey × grey matings, will be heterozygotes; (4) 'proven whites': rams shown by test-mating to be free of the presumptive scrapie allele, that is, of 'proven' double-dominant genotype. The progeny generations sired without interruption by 'proven' rams are designated F_1W, F_2W and so on. Assuming the original F_0 dams to be of the three genotypes in equal numbers, then the chance that an animal of the F_5W–F_6W generations carries the scrapie allele will be about 1 in 100, and of the F_8W–F_9W generations about 1 in 1,000.

Rams were test-mated with 'black' and 'grey' ewes to provide sufficient progeny for at least 10 offspring out of 'black' ewes or 22 out of 'grey' ewes, or a suitable proportion of each dam category, to be observed for at least 4½ yr. Assuming that only 80% of potential cases of scrapie, the *ss*, manifest the disease by 4½ yr, as a more recent study indicates[13], the probability that an allele-carrying ram in such a sire-progeny group will fail to produce an offspring affected within 4½ yr is $<1\%$. A ram with no affected progeny is assumed not to carry the scrapie allele and is a 'proven white'. Of 105 rams tested in eight flocks, 59 had more than one affected progeny and were discarded; 46 had no affected progeny; of these, 18 have proved to be free of the allele at a level of $P < 0.01$ or less, 3 to $P < 0.05$–0.01, 4 are now under test, and for 17, the data are insufficient to provide an assess-

ment, whereas in 4 cases test-mating was abandoned for other unrelated reasons. The 18 'proven white' rams were born and reared in 10 flocks, and were at stud in 3 flocks, which had scrapie present throughout the rams' lives. Ewes from 15 flocks, some with scrapie and some not, have been sent to these rams for mating.

This breeding programme confirmed three predictions of the genetic hypothesis[2,13–15]. (1) That no progeny of a 'proven white' ram should develop scrapie under any natural circumstances. 1,223 Progeny, 1,167 female and 56 male, of the 18 'proven white' rams were born and reared to adults in 15 flocks. 825 Females and 12 males were observed to $4\frac{1}{2}$ yr or older, many to 7 yr, the oldest being $13\frac{1}{2}$ yr. No case of scrapie has occurred in these sheep, although all 15 flocks contained affected animals during some part of the observation period, 1958–78. Sixty-three progeny were out of dams affected during their gestation or suckling, or manifesting scrapie within 2 yr; 46 were observed to $4\frac{1}{2}$ yr or older, with 25 observed to $7\frac{1}{2}$ yr and some to 11 yr; no clinical signs of scrapie were observed. Eight of the oldest animals, which had lived continuously in contact with clinical scrapie, showed no microscopical evidence of scrapie or of the common nonspecific senile changes. Data on the progeny of the first 'proven white' ram, kept in a high incidence environment, are shown in Table 1*b*. (2) That cases will reappear in the F_2 backcrosses of 'grey' parents sired by 'proven white' rams. In the high incidence flock cited in Table 1, matings of two heterozygous F_1W rams with known allele-carriers provided 21 progeny observed to $4\frac{1}{2}$ yr or older, of which five developed scrapie. (3) That consecutive top crosses of 'proven rams' should so reduce the scrapie-allele frequency that the disease will disappear. 308 Females and 18 males of the F_2W–F_6W generations remain under observation and free of clinical scrapie. Figure 1 shows the gradual disappearance of scrapie from one severely affected flock following the retention of the progeny of 'proven white' rams. No case has occurred in the main flock since the 1968 cohort, although two females retained for ram test-mating and six introduced stud rams were affected up to 1976. One F_5W ram carried the allele, derived from an affected great-great-great-grandmother and passed 'silently' without clinical illness through the intervening generations. In the breeder group, which has been using some 'proven white' rams and their sons since 1962, continuous data for 1953–78 are available in 13–18 flocks with 1,900–2,900 flock ewes. The attack rate was 0.4% in 1953–54, reached a peak of 3.2% (85 cases) in 1963–64, and then declined gradually to 0.5% in 1972–73, and 0.2% in 1976–77, with no new cases in home-bred sheep since 1977.

* Presumed very low *s* allele frequency based on family, flock and breeder group records over 20 yr.

† Based on assumption of 85% of total manifestation completed by age $4\frac{1}{2}$ yr (ref. 2).

Figure 1 also shows that the recessive gene concept provided precise explanations of the variable occurrence of the disorder, given the genotypes of the dams. Table 1 amplifies this analysis during periods of high and low flock attack rates. The agreement with the mendelian predictions is very close. This is confirmed by the summary of the nine reciprocal matings shown in Table 2, those in section *a* being from the flock in Fig. 1, and those in section *b* from three other flocks of the same breeder-group and free of scrapie since 1953.

After a 20-yr breeding programme based on my genetic hypothesis, scrapie has disappeared in the breeder group as predicted. Although our affected sheep carried the scrapie

TSEPA, I doubt that it is ever communicable outside the laboratory. There is no good evidence for dissemination of the disease by a communicable agent[10,11], by placental cannibalism[17], by vertical transmission from the dam[18], or through the action of a dominant susceptibility gene[19,20]. I conclude that in the sheep population studied and probably in most farm sheep in Britain (1) natural scrapie is determined, primarily, by an autosomal recessive gene expressed fully in both sexes; (2) no F_1 progeny of a 'proven' allele-free ram will develop scrapie, whatever the scrapie status of its dam or its exposure to cases of the disease; (3) the scrapie attack rates among the nine progeny groups derived from the reciprocal crosses of the three parental genotypes will conform to the predictions of Mendel's law; (4) the practical control of the disease, and its elimination if desired, may be achieved by the use of allele-free rams and the retention of their progeny; (5) the dissemination of natural scrapie does not depend on a naturally communicable parasitic agent; and (6) the hypothesis most consistent with present evidence[2,10,15,16] is that the scrapie TSEPA is formed *de novo* in each affected animal by the metabolic activity of the natural recessive gene[2,16]. A more detailed account of this work will be published elsewhere[21].

I thank Mrs E. Beck and Dr A. A. Vince for assistance with the histopathological assessment, and Dr G. J. Draper for help with the statistics.

In vitro transformation of cultured cells from *Nicotiana tabacum* by *Agrobacterium tumefaciens*

CROWN GALL, the plant tumour of many dicotyledonous and some monocotyledonous species, is caused by *Agrobacterium tumefaciens* infection after wounding[1]. Crown gall cells, unlike cells derived from healthy plants, have the ability to proliferate indefinitely in culture without the growth hormones auxin and cytokinin[2]. The properties of the tumours, such as morphology (rough or smooth type) and the synthesis of the unusual amino-acid derivatives octopine or nopaline, are determined by the tumour-inducing (TI) plasmid present in the virulent bacterial strains[3,4]. The presence of at least a part of the plasmid has been demonstrated in the DNA of the tumour cultures[4]. Transcription of this fragment was also demonstrated in the cells of the tumour tissues[5,6]. These findings seem to confirm the involvement of the TI plasmid in crown gall disease. However, it is not known if introduction of the TI plasmid alone into the plant cells is sufficient to obtain transformation of healthy plant cells into tumour cells. A fundamental approach to this question involves the development of an *in vitro* transformation system which can use TI plasmids of *A. tumefaciens* as vectors of genetic material in experiments to modify the genetic information of plants. We report here the transformation of tobacco cells by virulent strains of *A. tumefaciens*, the isolation and characterisation of

Table 1 Number of colonies in hormone-free medium after incubation of SR_1 cells with different strains of *Agrobacterium*

Bacterial strain	No. of plates seeded	No. of colonies	Frequency (approximate)
LBA 4001 (p)	4	4	1×10^{-4}
LBA 4013 (p)	9	34	6×10^{-4}
LBA 4011 (c)	6	—	—
LBA 305 (p)	6	1	1.5×10^{-5}
LBA 301 (np)	6	—	—

To obtain SR_1 cells, protoplasts were isolated[9] from sterile shoots[10] and cultured in K_3 medium[9,10] supplemented with naphthalene acetic acid (0.1 mg l^{-1}) and kinetin (0.2 mg l^{-1})[12]. The protoplasts were first kept in the dark for 24 h followed by 48 h at 2,000 lx. The cells were mixed with bacteria in a concentration of 10^5 cells per ml and 10^7 bacteria per ml. They were incubated at 20 °C for 32 h in K_3 medium. The light intensity during this incubation and all further treatments was 2,000 lx. After incubation free bacteria were removed by repeated washing and the tobacco cells (10^4 per ml) were cultured in K_3 medium supplemented with vancomycin (250 mg l^{-1}), carbenicillin (200 mg l^{-1}) and streptomycin (200 mg l^{-1}). Three weeks later the colonies were collected by centrifugation, washed with hormone-free medium, and plated in Petri dishes (10 cm) into hormone-free K_3 medium solidified with 0.5% agar. The concentration was approximately 10^4 colonies per plate. This solid medium contained the same antibiotics as the previous liquid medium, plus erythromycin (200 mg l^{-1}). Bacterial strains: LBA 4001, wild type *A. tumefaciens* Ach 5; LBA 4013, mutant of Ach 5 with a TI plasmid that is derepressed for transfer and constitutive for the octopine enzyme; LBA 4011, an avirulent derivative of Ach 5, cured of TI plasmid by growth at 37 °C, rifampicin resistant; LBA 301, wild type *A. radiobacter* S1005, non-pathogenic; LBA 305, S1005, converted to a pathogen by the introduction of a B6 octopine TI plasmid. p, Pathogen, carrying TI-plasmid; c, plasmid free, non-pathogen; np, non-pathogen.

0028–0836/79/0277—0129$01.00

transformed calli and the regeneration of shoots with a distinct tumour marker.

Preliminary studies with mixed populations of healthy tobacco cells and B_6S_3 crown gall tumour cells were carried out to define optimal conditions for recovery of transformed cells. These experiments were based on the properties of the tumour cells, such as hormone-independent growth and the synthesis of octopine, and on the properties of the *Nicotiana tabacum* SR_1 cells, such as hormone-dependent growth, streptomycin resistance and formation of green colonies in culture medium. It was found that protoplasts, cells or colonies of B_6S_3 cells were able to grow in hormone-free medium whereas those obtained from the SR_1 plants could not grow in these conditions.

SR_1 protoplasts were isolated from leaves of sterile shoots and cultured for 3 d in medium with hormones. During this period the protoplasts regenerated new cell walls and a few underwent the first cell division.

The bacterial strains used were the virulent strains LBA 4013, LBA 4001 and LBA 305, and the non-virulent strains LBA 4011 and LBA 301; the strains are specified in the legend to Table 1. For transformation, the SR_1 cells were mixed with bacteria and incubated for 32 h. During this incubation, aggregation of cells and bacteria was observed. Cells aggregated within a few hours when LBA 4013 bacteria were present, whereas aggregation in the presence of LBA 4001 or LBA 4011 was observed only after at least 5 h. Incubation with LBA 305 and LBA 301 resulted in a slight aggregation that was observed only after 24 h. After incubation, the cells were washed and cultured in liquid medium supplemented with hormones, followed by subculture in solid medium without hormones. This selective medium allowed only hormone-independent cells to grow. Colonies, which were scored after a culture period of 7 weeks (Table 1), were only observed when SR_1 cells were incubated with virulent strains of *A. tumefaciens* and not in control plates when SR_1 cells were incubated with *A. tumefaciens* strains not containing the TI plasmid either after curing or as an original non-pathogenic isolate.

Colonies were isolated and subcultured for further growth and characterisation on selective and non-selective medium; their properties are listed in Table 2. Most of the SR_1–4013 calli retained the ability to proliferate hormone independently after subsequent passages on hormone-free medium. Some of these calli demonstrated lysopine dehydrogenase (LpDH) activity whereas others did not. It is obvious that the group of calli which are hormone independent and LpDH positive is the most conspicuous, because it contains the highest number of calli in which the two tumour markers are observed. Another interesting callus is the SR_1–4013–5, which apparently lost its ability to proliferate hormone independently even though LpDH activity was present.

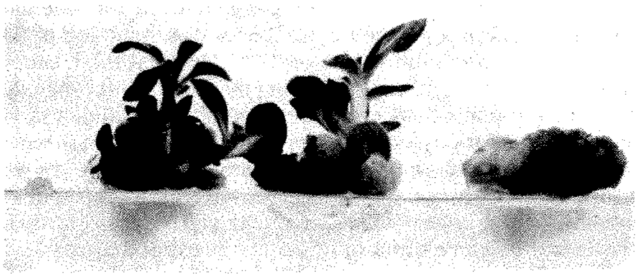

Fig. 2 Five-months-old differentiating SR_1–4013–1 callus obtained after incubation of SR_1 cells with *A. tumefaciens* LBA 4013. The callus was isolated from K_3 medium without hormones and cultured for 6 passages in LS medium without hormones, solidified with 0.8% agar at 2,000 lx.

Before comparing the tumorous calli obtained from these *in vitro* transformation experiments with calli obtained *in vivo* after wounding and infection of plants with the same virulent bacterial strains, it is worth mentioning that the *in vivo* calli, which we have isolated with the LBA 4013, always contain both tumour markers. These calli have been cloned and subcultured for more than 2 yr during which time no reversion to hormone dependence or LpDH deficiency has been observed. This indicates that the loss of tumour markers in callus tissues is a specific phenomenon for those tumours obtained after *in vitro* transformation. Similar observations, concerning the separation of these tumour markers in callus cultures, have not been published before.

The most likely explanation for the observation that during subculture not all the hormone-independent calli contained LpDH activity and for the detection of enzyme activity in hormone-dependent calli is segregation of genes coding for these different properties of the tumour cells. This phenomenon is now being investigated by experiments involving the isolation of TI DNA from the calli and its characterisation using the Southern blot procedure[8]. A correlation between the presence of certain parts of the TI DNA and the expression of certain tumour markers has recently been found in *in vivo* transformation experiments by the isolation of virulent plasmid deletion mutants of *A. tumefaciens* which have lost the property to establish octopine synthesis in tumours which they induce[15,16].

Although most calli were isolated after incubation with the LBA 4013 strain, Tables 1 and 2 show that four calli originated from the use of LBA 4001 and one callus from the LBA 305. From control experiments, in which the non-virulent strains LBA 4011 and LBA 301 were used, no colonies have been isolated (Table 1). The four SR_1–4001 calli did not have LpDH activity; two of them even lost their hormone-independent

Table 2 Characterisation of cell strains obtained after incubation of SR_1 cells with pathogenic strain of *Agrobacterium*

Cell–bacterium combination	Callus no.	Streptomycin resistance	Growth without hormones	LpDH activity	Regeneration
SR_1–4013	1; 3; 22	+	+	+	+
	4; 10; 13; 14; 15 17; 18; 19; 20; 21; 23; 24; 25; 26; 29; 30; 31; 33; 34	+	+	+	−

SR_1–305	1	+	+	−	−

Colonies were isolated and subcultured in hormone-free LS medium[13]. Their streptomycin resistance was tested by culturing them in LS medium with hormones and streptomycin (1 mg ml^{-1}). The media were solidified with 0.5% agar. The light intensity was 2,000 lx.

character. The SR_1–305 callus seemed to be hormone independent and negative for LpDH activity. Calli which were both hormone dependent and LpDH negative were recovered after incubation with the LBA 4013 and the LBA 4001 bacterial strains. Although tumour markers can no longer be detected in these calli after four passages, they were isolated as hormone-independent colonies and obtained from the selective medium from those cultures of cells incubated with virulent bacterial strains.

Our results suggest that the calli in which tumour markers were no longer detectable after four passages have lost their transformed character by loss of the tumour-determining genes during subsequent cell divisions. The significance of these calli is also being studied.

The different numbers of transformed colonies observed by using the three virulent bacterial strains (Table 1) indicate a high efficiency of transformation by the LBA 4013, as compared with the LBA 4001 and the LBA 305 strains. This might be related to the ability of the LBA 4013 to transmit the TI plasmid to other bacteria in a high frequency[15]. Further experiments will show whether these differences are statistically significant.

The colour of the calli varied from white to green (results not shown), but a positive correlation between colour and the other phenotypic traits could not be established. The same is true of the capacity to produce shoots (Table 2). These arose on two LpDH-negative calli, whereas three LpDH-positive calli could also regenerate shoots. These shoots were also LpDH positive (Fig. 1). Figure 2 shows one of the LpDH-positive calli with the shoots. The morphology of the LpDH-positive shoots differs from normal SR_1 shoots in that the transformed shoots show an extensive lateral shoot formation and almost no size growth. The stems and the leaves are relatively thick, and there is almost no apical dominance. Roots cannot be induced. Regeneration in the way described for the *in vitro* transformed SR_1 calli has not been observed on tumorous calli obtained after *in vivo* transformation of shoots of *N. tabacum*.

Extension of the observations presented here, using purified TI-plasmid DNA as the transforming vehicle, is now being carried out. Preliminary results from these experiments indicate that TI DNA alone is sufficient for tumour induction in cultured plant cells. The successful transformation of individual plant cells by *A. tumefaciens*, its regeneration into shoots in which tumour markers are expressed, and the possibility of isolating new bacterial strains containing recombinant TI plasmids[17] provide new tools for the introduction of foreign genetic information into plant species.

We thank Dr P. M. Klapwijk for selecting the appropriate bacterial strains, Dr L. A. B. M. Otten for help with the LpDH activity assay and Dr J. Semancik for critical reading of the manuscript. L. M. was a fellow of the International Agricultural Center.

Rat × rat hybrid myelomas and a monoclonal anti-Fd portion of mouse IgG

MONOCLONAL antibodies can be produced by cultures of permanent cell lines derived by fusion of suitable myelomas with spleen cells from immunised animals[1]. So far, mainly two mouse myelomas, X63-Ag8 and NSI/1-Ag4.1, have been used for this purpose[1,2]. When cells from immunised mice are used in the fusion, the mouse × mouse hybrid myelomas can be grown as tumours in appropriate mouse strains. We describe here the preparation and use of a new clone of a rat myeloma, which is suitable for the derivation of rat × rat hybrid myelomas producing specific rat antibodies. The spent medium of hybrid myeloma cultures usually contains 1–20 $\mu g\ ml^{-1}$ antibody. The serum and ascites of the tumour-bearing mice, with few exceptions, yield 1–20 $mg\ ml^{-1}$ of antibody, which is 1,000 times more concentrated and very convenient for larger preparations.

There are several reasons for preferring rats to mice for the production of monoclonal antibodies. The yield of serum and ascitic fluid is about 10 times better in tumour-bearing rats than mice, an overwhelming economic advantage in large scale production. Although there is a marginal increase in the generation time (10 weeks in the rat and 8 in the mouse) the rat litters are usually large. The derivation of hybrid myelomas using cells from immunised rats is a very successful procedure for deriving rat alloantibodies or anti-mouse xenoantibodies[3,4], but because the derived lines are of mouse × rat origin the growth of tumours *in vivo* in either rats or mice requires rather elaborate procedures or special strains. Clearly, rat × rat fusion would be advantageous for making xenogeneic anti-mouse and allogeneic anti-rat antibodies, as well as others, where large scale production is anticipated. This requires a suitable parental rat myeloma line.

Myeloma tumours in the Lou strain of rats have been available for some time[5]. One of them, R210, has been grown in culture and an azaguanine resistant mutant (210.RCY3.Ag1) prepared. It secretes κ chains and was used in the first successful fusion between two myelomas[6]. When tested for its ability to fuse to normal or immunised rat spleens it gave disappointing results. It was twice subcloned in soft agar and the clone finally selected for further study was called Y3-Ag1.2.3. It gave no revertants when batches of 10^7 cells were tested. Fusion efficiencies were at first disappointing and the line was grown continuously in a spinner flask and tested for fusion efficiency at

Table 1 Species specificity of YA2/40

Species	Serum dilution giving 50% inhibition
Mouse	1:10,000
Guinea pig	1:2,000
Rabbit	1.40
Horse	>1:10*
Human	>1:10*
Rat	>1:0*

Inhibition of [^{3}H]YA2/40 binding to Sp2 coated SRBC was as described in Fig. 2.

* No inhibition detected at 1:10.

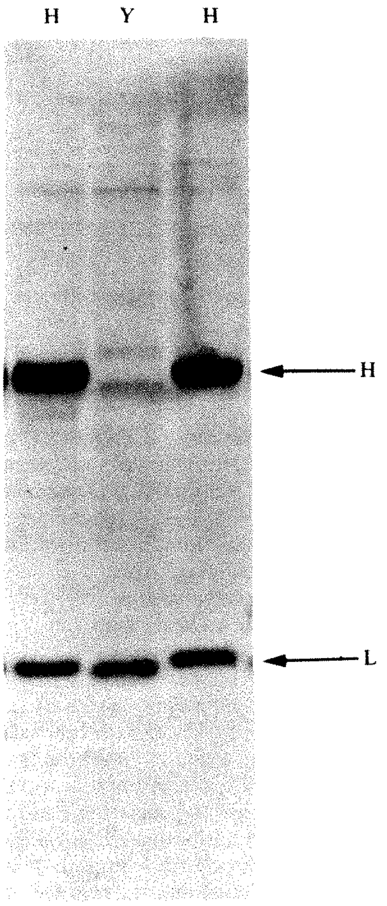

Fig. 1 Analysis of Ig secreted by the rat hybrid myeloma clone YA2/40 H(LK). Cells were incubated for 24 h with ^{14}C-lysine and supernatants were analysed[2] by SDS-polyacrylamide (10%) gel electrophoresis after total reduction. Y refers to Y3-Ag1.2.3 (control); H to Y2/40 H(LK) clone. DA rats were immunised by five footpad injections at 3-week intervals with 100 μg of mouse IgG in complete Freund's adjuvant and boosted by intravenous injection without adjuvant 4 days before fusion. Supernatants were tested 13–15 days after fusion by indirect haemagglutination as follows: 2.5×10^8 SRBC were coated by incubation for 1 h at room temperature with 5 ml of culture supernatants of anti-SRBC hybrid myelomas[2] minimally diluted to avoid agglutination. They were centrifuged and the pellet resuspended in 2.5 ml of phosphate-buffered saline (PBS). Aliquots of 25 μl were distributed in V-bottom microtitre trays and 25 μl of supernatant added to each well. After 1 h incubation the plate was centrifuged at 200*g* for 4 min and then kept in a 45 ° slope for 30–60 min. Culture YA2/40 was selected in this way and cloned twice in soft agar.

different times. The first successful fusion was obtained after 5 months of continuous growth. Using about 5×10^7 Y3 cells and 10^8 spleen cells the fusion efficiency has improved to a stage where it is comparable to the mouse lines. The Y3 rat cells and their hybrid derivatives are much smaller in appearance than the mouse X63-Ag8 cells. Early stages of hybrid growth are less obvious under the microscope. Y3 cells grow very well on DMM supplemented with 5% or less fetal calf serum and the clonability in soft agar is very good. The line and the hybrids derived from it give rise to rather diffuse clones, instead of the tight ones given by mouse × mouse hybrids.

Our first successful derivation of a rat monoclonal antibody by fusion of Y3-Ag1.2.3 was with spleen cells from a DA strain rat which had been hyperimmunised with mouse IgG (see Fig. 1 legend). The fusion protocol used polyethylene glycol 1500 as previously described[3]. The hybrid culture was divided into 48 subcultures. In this experiment only 6 showed hybrid growth. The spent medium of the hybrid cultures was tested by indirect haemagglutination of sheep red blood cells (SRBC) which had been sensitised with different mouse monoclonal antibodies specific for SRBC[2]. One hybrid was clearly positive when the SRBC were coated with Sp3 (an IgG1) but negative when coated with Sp2 (an IgG2b) or Sp1 (IgM). The positive hybrid was subsequently cloned in soft agar and 8 individual clones were selected. All were found to be positive by the same test. The antibody secreted by each clone was internally labelled with ^{14}C-lysine and analysed by SDS-polyacrylamide gel electrophoresis and isoelectric focusing (Fig. 1) (data not shown). All appeared to be identical, revealing a heavy chain band of about 50,000 MW and a single band present in the light chain zone. We were not able to demonstrate the presence of the two expected light chains (the myeloma parental and the antibody specific light chains). It is quite possible that both have very similar mobilities. Three of the above clones were cloned again to ensure purity and increase stability. One of these subclones was named YA2/40 H(LK) and used in all the experiments described below.

Binding of internally labelled [^{3}H-Lys]YA2/40 to cells coated with different classes of anti-SRBC antibody showed that YA2/40 recognised mouse IgG but not IgM. Binding to Sp1 (IgM) coated cells gave the same value as the background binding to uncoated cells. Binding to Sp3 (IgG1) and Sp2 (IgG2) coated cells was 4.9 and 35 times background respectively, a difference which correlates with the number of antigenic sites recognised by Sp2 and Sp3 (the number of antigenic sites recognised by Sp1 is intermediate between Sp2 and Sp3; C. D. Wilde, A. Williams and C. M., unpublished). The failure of YA2/40 to agglutinate Sp2 coated red cells although it agglutinated Sp3 coated cells (see above) remains unexplained.

Coating with Sp2 gives a sensitive procedure to assay for binding of [^{3}H]YA2/40, and further specificity studies were done by inhibition of this binding. These studies confirmed that YA2/40 recognised individual proteins of both $\gamma 1$ and $\gamma 2$ subclasses of IgG (Fig. 2*a*). Inhibition by an IgM was at least 50-fold less effective. At high concentrations of protein some inhibition was observed, probably because of IgG impurities in the preparation. The antigenic determinant in the IgG1 is located in the Fd region for the following reasons. The inhibition of binding by MOPC 21 is equally effective with its variant IF1 (a mutant lacking the CH3 domain[7]) and with the $F(ab')_2$ fragment of MOPC 21 which lacks the CH2 and CH3 domains[8]. In both cases the inhibitory titre on a molar basis was similar to the intact protein and slightly higher on a per weight basis (Fig. 2*b*). On the other hand the IF2 mutant protein (which lacks the CH1 domain) was a very poor inhibitor. The residual inhibition is probably due to a trace of IgG present in the IF2 purified from serum of tumour-bearing mice which can be detected by SDS-polyacrylamide gel electrophoresis. No intact H-chain was present in the $F(ab')_2$ while a trace impurity of 50,000 MW component was detected in the IF2 preparation (data not shown).

As regards species specificity YA2/40 seems to be completely negative towards human, horse or rat, but shows some degree of cross-reaction to rabbit serum. On the other hand it is inhibited quite effectively by guinea pig serum. This pattern of cross-

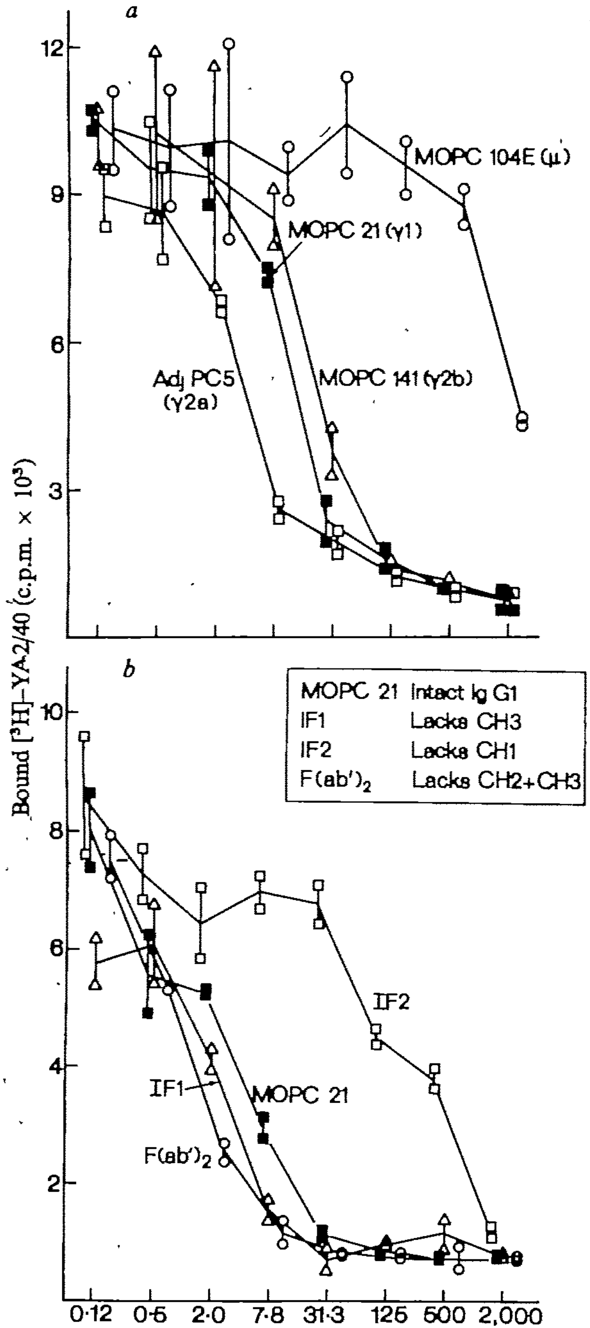
Fig. 2 Inhibition of YA2/40 binding to IgG coated cells by other immunoglobulins. 1.2×10^6 SRBC coated with Sp2/HL (IgG2b anti-SRBC) in 10 µl of PBS were distributed in U-shaped microtitre plates. After addition of 20 µl of inhibitor protein solution and 10 µl of ^{3}H-lysine-labelled YA2/40 (170,000 in *a*, 85,000 c.p.m. in *b*) and incubation at 4° C for 1 h, the cells were washed three times with cold PBS, the pellet lysed with 50 µl of H_2O and transferred to a scintillation vial. Counting was in 2 ml of scintillant (5 g PPO, 0.2 g POPOP, 540 g Triton X-100 and toluene to 1 l final volume). All proteins[8] were purified from serum by $(NH_4)_2SO_4$ precipitation and DEAE chromatography. $F(ab')_2$ fragment was prepared as before[7] and purified by Sephadex G-100 ultrafiltration. Internally labelled YA2/40 protein was prepared as follows: 5×10^6 YA2/40 H(LK) cells were incubated in 5 ml of lysine-free medium containing 0.2 mCi ml^{-1} ^{3}H-lysine; after 8 h incubation at 37 °C, 5×10^6 more cells were added and the incubation continued for another 12 h. The supernatant was collected and dialysed three times against 0.5 l of PBS.



reactivity indicates that the antigenic determinant involves a similarity of local structures in guinea pig and the different mouse subclasses which, however, differ completely from the human, horse and rat. A close inspection of the sequences of the CH1 of mouse γ1 (ref. 9), mouse γ2*a* (ref. 10), guinea pig γ2 (ref. 11), rabbit[12] and man γ1 (ref. 13) reveals few examples of such a pattern of sequence similarity. The most interesting sequence involves residues 209 (Ser in mouse and guinea pig, Asn in human), 206 (Pro or Ala in mouse and guinea pig, Lys in human) and 204 (Ala in mouse and guinea pig, Asn in human). This is a cluster of residues in an exposed corner near the V–C domains boundary in the tertiary structure of the Fab[14]. It is important to keep in mind that structures in Fab other than CH1 could be involved in the antigenic recognition, the deletion of CH1 having a general effect on the tertiary structure of the Fab. Elucidation of the rat and horse sequences could throw further light on the precise nature of YA2/40 determinant. YA2/40 H(LK) cells grow as solid tumours in F1 (Lou × DA) rats and the serum of the tumour-bearing rats contains 10–15 mg ml^{-1} IgG as measured by radial immunodiffusion, giving rise to a prominant myeloma band component in cellulose acetate electrophoresis. The tumour could also be grown as an ascitic tumour. This was achieved by an intraperitoneal injection of 0.5 ml of pristane about 2 weeks before the intraperitoneal injection of 5×10^7 cells (P. Wright, unpublished).

In a subsequent experiment, hybrids obtained from this line fused with spleen cells of an immunised rat were analysed by their ability to secrete Ig different from the myeloma parent. This was done by SDS-polyacrylamide gel electrophoretic analysis of the secreted products. Out of 12 cultures tested (all probably monoclonal) 11 secreted Ig chains and only 1 failed to secrete chains different from the myeloma parent. So, well over 60% of the tested cultures (and even of total number of growing cultures) secreted new immunoglobulin. This value is even higher than that obtained for the mouse system[2] and is in line with the hypothesis that the fusion between a myeloma cell and the heterogeneous population of cells present in the spleen is a highly selective event which favours the rescue of active antibody secreting phenotype. In a wider context it indicates that for the recovery of a transient differentiated function in the form of an immortal cell line, it is best to use a fusing parental cell which is phenotypically close to the normal phenotype one attempts to immortalise.

In conclusion, 210RCY3-Ag1.2.3 is a myeloma cell line suitable for the derivation of rat × rat hybrid myelomas. This seems a better alternative than the mouse × mouse hybrids for large scale production of monoclonal antibodies of potential general use in research, medicine and industry. The anti-mouse IgG monoclonal antibody described here is an example of such hybrids.

Continuous cell lines with specific killer T-cell activity

THE establishment of continuous cell lines with effector T-cell activity is an obvious starting point in the isolation and characterisation of the T-cell receptor complex. Although nature provided the plasmacytomas which played a key part in elucidating B-cell immunoglobulin structure, there are no known examples of naturally occurring lymphomas with effector T-cell activity. Initial success with fusions between plasma cells and plasmacytomas encouraged extrapolation of this technique to T cells and thymic lymphomas[1], but few promising results have so far been obtained. We have approached this problem by using the carcinogenic properties of mutagens to transform T lymphocytes responding in mixed lymphocyte culture (MLC), with the aim of isolating cell lines with killer T-cell activity. Here we report our success in the first step of isolating continuous, though antigen-dependent, killer T-cell lines.

We started with C.B20 (H–2^d BALB/c, Ig–1^b congeneic) mouse spleen cells responding to irradiated (3,000 R) C57BL/6 (H–2^b) spleen cells, in culture conditions described by McDonald[2]; 7 d after the second *in vitro* boost, cells were mutagenised (1 h) with (2 μg ml^{-1}) nitrosoguanidine. Mutagenised cells were restimulated twice more, then seeded at 10, 10^2 or 10^3 cells per well in Falcon Micro Test II tissue culture plates and cultured with 10^6 irradiated C57BL/6 spleen cells per well which also served as a feeder layer. Individual wells were scored for growth, and killing capacity was tested by adding 5×10^3 of HAT (hypoxanthine, aminopterin, thymidine)-sensitive ^{51}Cr-labelled EL4.BU target cells (addition of HAT medium after assay killed all remaining EL4 cells leaving HAT-resistant MLC cells to grow). Although some wells had high killing activity, these wells did not show good growth. There were 3 of 384 wells positive for growth from the 10-cell per well plates and 1 of 384 positive from the 10^2-cell per well plates. The four isolates were expanded by weekly stimulation with irradiated C57BL/6 spleen cells and tested for growth requirements as well as killer activity. Each isolate contained only Thy 1.2-positive cells as tested by anti-Thy 1.2 and complement lysis (data not shown).

As shown in Fig. 1, the four isolates have different killer-cell activities. The isolates 100.1 and 10.3 show typical H–$2D^b$ and H–$2K^b$-specific killing, respectively. Isolate 10.2 killed only in the presence of concanavalin A (Con A) or after Con A stimulation, and isolate 10.1 killed only EL4 and not C57BL/6 lipopolysaccharide blast targets. The specificity of killing exactly paralleled that of growth stimulation; for example, 10.3, which killed B10.A (5 R) (K^bD^d) but not B10.HTG (K^dD^b) was stimulated to grow with B10.A (5 R) but not B10.HTG. Isolates 10.2 and 10.1 were tested for growth with C57BL/6, B10.HTG and B10.A (5 R) irradiated spleen. The results show that 10.1 was specifically stimulated by B10.A (5 R) H–$2K^b$ (Fig. 2), although killing activity waned over the 150-d test period (Fig. 1). Isolate 10.2 showed a differential growth response, as C57BL/6 stimulated better than B10.A (5 R), and B10.HTG gave virtually no growth. The complex growth and killing properties of 10.2 have been studied in some detail without revealing any simple explanation; however, this isolate may well provide new insights on Con A-dependent killing. We found that 10.2, stimulated with Con A for 2 d then washed in medium containing α-methyl-D-mannoside, killed EL4 but not P815 (H–2^d) targets. The isolate 10.2 could not be maintained in culture with either Con A or Con A-supernatant as stimulants, as indeed was true of all other isolates. The cytolytic efficiency of these different isolates varied from near normal MLC values (for example, 100.1) to zero (such as 150-d 10.1), suggesting that either the populations have different intrinsic killing efficiencies, or both active and inactive killers exist in the same population. When the isolates

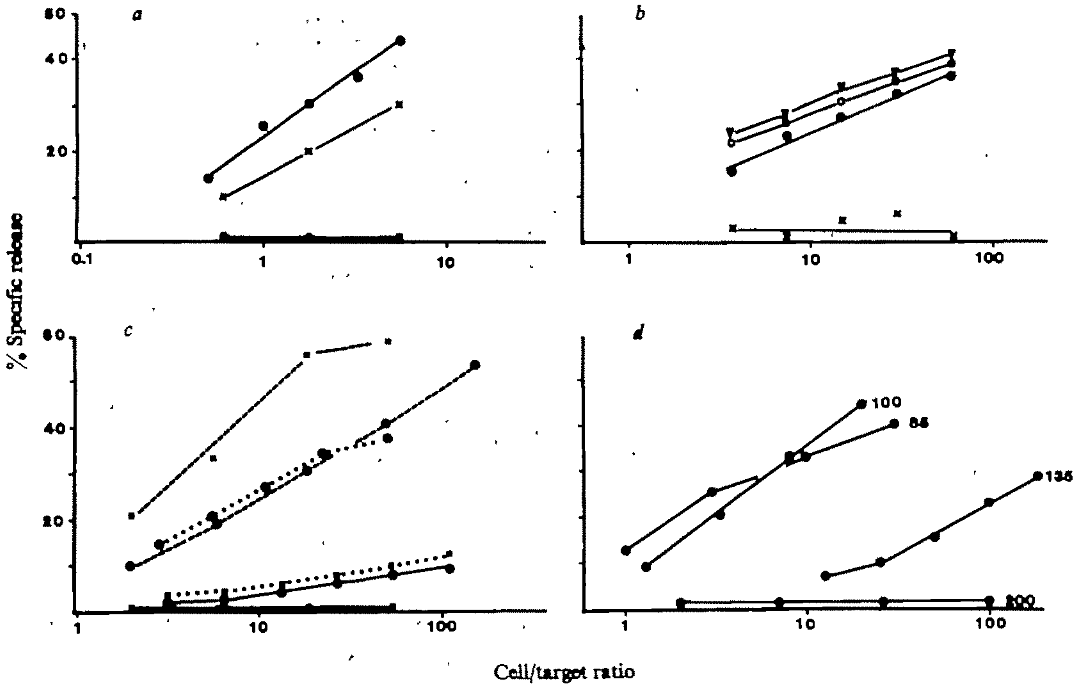

Fig. 1 Cytotoxic activities of four cloned isolates of T cells obtained from a C.B20 (H–2^d) anti-C57BL/6 (H–2^b) one-way MLC after multiple stimulation and mutagenesis *a*, Isolate 100.1; *b*, isolate 10.3; *c*, isolate 10.2, *d*, isolate 10.1. Target cells labelled with ^{51}Cr were EL4 (●), P815 (□) and 2 μg ml^{-1} Con-A blasted spleen cells from the congeneic mouse strains C57BL/6 (H–$2K^b$–D^b) (▽), B10.A (5 R) (H–$2K^b$–D^d) (○) and B10.HTG (H–$2K^d$–D^b) (×). Cytotoxicity assays were carried out in flat-bottomed microtitre plates (Falcon 3040) in a total volume of 0 3 ml with 10^4 ^{51}Cr-labelled target cells and varying numbers of clone effector cells. The amount of ^{51}Cr released during 5 h incubation at 37 °C was calculated on the basis of 0 1-ml samples and the per cent specific target cell lysis was calculated according to the formula. [(experimental c.p.m. – spontaneous c.p.m.)/(total c.p.m. – spontaneous c.p.m.)]100 In experiments using tumour cell and Con A blast targets, spontaneous release was less than 10% and 25–35%, respectively. Isolate 10.2 (*c*) was assayed in the presence (– – – –) or absence (——) of 10 μg ml^{-1} Con A in the cytotoxic test. In one experiment 10.2 cells were cultured in the presence of 2 μg ml^{-1} Con A for 48 h, then washed and incubated in 0.2 M α-methyl-D-mannoside for a further 2 h before testing in the cytotoxicity assay (·····). Isolate 10.1 (*d*) was assayed periodically over 154-d, the numbers indicating the time in days.

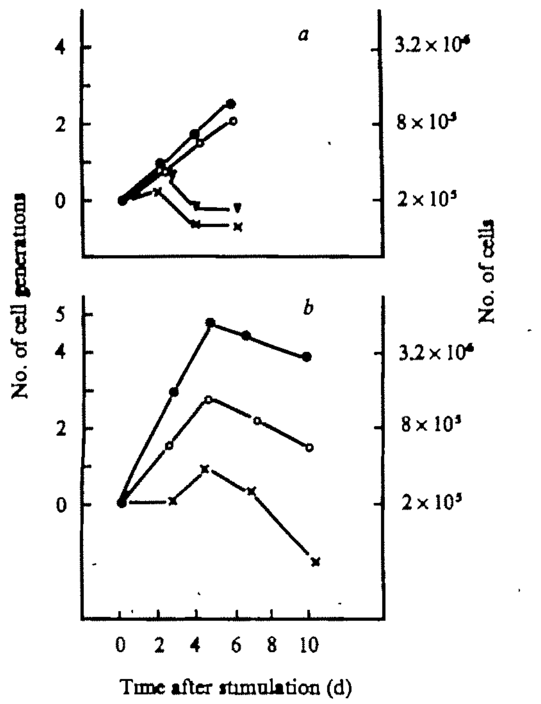

Fig. 2 Isolates 10.1 (*a*) and 10.2 (*b*) were stimulated with 3,000 R irradiated spleen cells from C57BL/6 (●), B10.A (5 R) (○), B10.HTG (×) and C.B20 (▽). In all experiments cells were grown in Dulbecco modified Eagle's medium supplemented with 10% fetal calf serum, 5×10^{-5} 2-mercaptoethanol, 8×10^{-2} M glutamine and non-essential amino acids. In the primary MLC, 2.5×10^{-7} C.B20 spleen cells were mixed with 2.5×10^{7} irradiated C57BL/6 spleen cells in 20 ml medium in Falcon flasks (3012) and incubated for 11 d in flasks standing upright. Subsequent stimulations, whether in flasks, Micro wells or Linbro wells were done at a concentration of about 4×10^{4} stimulator cells mm^{-2} tissue culture surface and 0.01 of the number of responder cells (except in the cloning procedure where the number of responding cells varied). All cultures were incubated at 37°C with an atmosphere of 15% CO_2 in air.

are recloned it will be possible to distinguish these possibilities although our guess would be that low killing efficiency is more conducive to long-term survival of these cells in culture as exemplified by isolates 10.2 and 10.1.

Previous reports from other laboratories have shown that MLC cells can be maintained for long periods[3,4], and in one case killer cells were 'cloned' in agar[5]. The use of soft agar to clone MLC cells was possible because cells could be maintained by Con A-supernatant stimulants, whereas in our case MLC cells require cellular stimulants and cannot be seeded in soft agar. The isolates we have obtained after growing MLC cells at limiting dilution are certainly clonal with respect to both the minimal growth unit and specificity; however, it is still impossible to conclude rigorously that a growth unit is in fact a single T-killer cell. Work is in progress to further mutagenise the isolates for the selection of antigen-independent killer T cells which can be formally cloned and studied as a homogeneous population of effector T cells. Recently, we have been able to use a more efficient carcinogenesis technique (developed by P. Patek and J. Collins, personal communication), which is based on continuous exposure of cultures to methylcholanthrene.

The ability to clone MLC responses seems to depend on prior mutagenesis, and with the techniques described here it is relatively straightforward to isolate growing clones of effector T killers. Further experiments are in progress to test if these killer-cell clones can act as abnormal suppressor cells in the system recently described by Epstein and Cohn[6].

We thank Dr Melvin Cohn for his support and interest in this work, and Ms M. Fairhurst for technical assistance. This work was supported in part by grants to Dr M. Cohn from the CI (R01 CA19754) and the Armand Hammer Foundation. R.D.P. was the recipient of a fellowship from Deutsche Forschungsgemeinschaft.

Effects of *S*-lactoylglutathione and inhibitors of glyoxalase I on histamine release from human leukocytes

THE enzyme responsible for the conversion of methylglyoxal to lactic acid by animal tissues was first named glyoxalase[1,2]. It was later shown that there are two glyoxalase enzymes[3]. The first (glyoxalase I) converts methylglyoxal and reduced glutathione to *S*-lactoylglutathione and the second (glyoxalase II) converts this compound to D-lactic acid, regenerating glutathione in the process. These enzymes are very widely distributed[4] and as yet have no clearly defined function(s). I describe here the enhancement of anti-IgE-induced histamine release by *S*-lactoylglutathione and its inhibition by an inhibitor of and an alternative substrate for glyoxalase I. These two compounds should, of course, decrease the production of endogenous *S*-lactoylglutathione. These experiments were undertaken for two reasons. First, a study from my laboratory has provided evidence that *S*-lactoylglutathione modulates microtubule assembly *in vitro*[5] while the release of histamine from leukocytes is a secretory process thought to require an intact microtubule system[6,7]. Second, concanavalin A has been shown to cause histamine release from human leukocytes[8,9] and has also been found to activate the two glyoxalase enzymes in lymphocytes and polymorphonuclear leukocytes[10].

Leukocytes prepared from the blood of normal donors by dextran sedimentation as previously described[11] were subjected to hypotonic lysis (18 ml of ice-cold distilled water for 20 s followed by 2 ml of 9% NaCl) to remove contaminating red blood cells. They were incubated with anti-IgE and other compounds for 45 min at 37 °C in a balanced salt solution consisting of (mM): NaCl, 110; KCl, 5.0; $CaCl_2$, 0.6; $MgCl_2$, 1.0; and PIPES buffer, 25 mM, adjusted to *p*H 7.3 with 40 mM sodium hydroxide. At the end of the incubation period the cells were centrifuged at 1,000*g* for 90 s and histamine released into the medium was determined using an automated extraction procedure[12].

The effects of *S*-lactoylglutathione on histamine release induced by two different levels of anti-IgE from the cells of normal non-atopic donors are shown in Fig. 1. The dose–response curve to anti-IgE is bell-shaped[13] with maximum release varying from zero to approximately 60 or 70% depending on the individual from whom the cells are taken. The lower of the two anti-IgE concentrations studied is below that required for optimum release while the higher concentration is slightly above it. As can be seen, *S*-lactoylglutathione caused a small increase in release from the cells of 6 out of 7 donors at the lower anti-IgE concentration and from the cells of 9 out of 10 donors at the higher anti-IgE level. This enhancement is statistically significant with $P < 0.003$ (Student's paired *t*-test) or $P < 0.001$ (Wilcoxson matched-pairs signed-ranks test).

0028-0836/79/0277—0135$01 00

The effect of various concentrations of S-lactoylglutathione (0.2–2×10^{-4} M) on histamine release were studied to establish the concentration necessary for optimum enhancement. The dose–response relationship varied with the cells of different individuals. With the cells of three out of five donors, maximum enhancement was seen at an S-lactoylglutathione concentration of 2×10^{-4} M. With the cells of one donor enhancement in the presence of 5×10^{-5} and 2×10^{-4} M S-lactoylglutathione was identical (51 to 59%) and with the fifth donor 5×10^{-5} M S-lactoylglutathione increased release from 60 to 73% while release in the presence of 2×10^{-4} M was only 64%. In the absence of anti-IgE, S-lactoylglutathione did not itself release histamine. As the preparation contained glutathione (Sigma) and this is one of the metabolic products of S-lactoylglutathione, the effect of glutathione (2.5×10^{-4} M) was studied in seven experiments. It never enhanced histamine release and with the cells of two individuals somewhat (5–15%) inhibited release.

To investigate the role of S-lactoylglutathione in histamine release further, two structurally dissimilar compounds both capable of interacting with glyoxalase I and thereby decreasing S-lactoylglutathione formation were studied. The first of these, glutaryl-S-(p-bromobenzyl)-L-cysteinylglycine (PAL6-25-1) is an analogue of glutathione that is not metabolised by the enzymes capable of degrading glutathione[14]. It inhibits glyoxalase I from yeast with a K_I value of 0.32 mM, but apparently binds to a different site from that of glutathione[15]. The second compound, phenylglyoxal (Aldridge), is an analogue of methylglyoxal (Sigma) and is a substrate for glyoxalase I (ref. 16), forming S-mandelylglutathione rather than S-lactoylglutathione. S-Mandelylglutathione is a poor substrate for glyoxalase II, with a V_{max} for this enzyme only a twentieth that of S-lactoylglutathione[17]. As can be seen from Table 1, both PAL6-25-1 and phenylglyoxal inhibited histamine release in a dose-dependent manner. Furthermore, the simultaneous addition of S-lactoylglutathione more than reversed the inhibitory effect of PAL6-25-1 and also partially (donor 1) or completely (donor 2) reversed the inhibition caused by phenylglyoxal. This reversal provides good evidence that PAL6-25-1 inhibits histamine release because it decreases endogenous S-lactoylglutathione formation. Phenylglyoxal is possibly acting in the same way although it is also conceivable that the S-mandelylglutathione formed from phenylglyoxal is an inhibitor of the action of S-lactoylglutathione.

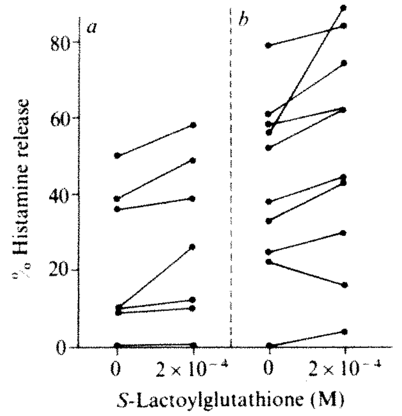

Fig. 1 Effect of S-lactoylglutathione on histamine release from human leukocytes induced by anti-IgE. Leukocytes from normal individuals were incubated in duplicate with anti-IgE (a, 8.3×10^{-3} μg ml^{-1}; b, 0.167 μg ml^{-1}) and with or without S-lactoylglutathione as described in the text. The release reaction was initiated by adding cells prewarmed to 37 °C to tubes already containing all desired compounds. The average difference between duplicate measurements (higher value minus lower value divided by lower value × 100) was 3.8%. S-lactoylglutathione was prepared enzymatically by incubating a neutralised mixture of 20 mM methylglyoxal and 25 mM reduced glutathione with glyoxalase I (4 units ml^{-1}) at room temperature for 1 h. In the presence of excess glutathione the conversion of methylglyoxal to S-lactoylglutatione was complete. The methylglyoxal was purified by steam distillation[16] followed by passage (at a concentration of 50 mM) over Dowex-1.

Table 1 Effects of PAL6-25-1, phenylglyoxal and S-lactoylglutathione on histamine release from human leukocytes

Additions Inhibitor	S-Lactoylglutathione 2×10^{-4} M	% Histamine release (mean ± s.d.) Donor 1	Donor 2
None	−	58 ± 4	64 ± 2
	+	71 ± 3	60 ± 1
PAL6-25-1	−	45 ± 0	51 ± 3
3×10^{-4} M	+	76 ± 2	66 ± 2
PAL6-25-1	−	36 ± 4	41 ± 0
10^{-3} M	+	85 ± 3	70 ± 2
Phenylglyoxal	−	32 ± 1	48 ± 2
10^{-5} M	+	58 ± 4	62 ± 2
Phenylglyoxal	−	9 ± 2	22 ± 1
3×10^{-5} M	+	32 ± 2	60 ± 2
Phenylglyoxal	−	7 ± 1	9 ± 2
10^{-4} M	+	16 ± 3	51 ± 4

Leukocytes from two normal individuals were incubated in triplicate as described in the text. The cells were preincubated for 5 min with PAL6-25-1, phenylglyoxal and/or S-lactoylglutathione after which anti-IgE (final concentration 3.3×10^{-2} μg ml^{-1}) was added and the incubation continued for 45 min. Donor 2 was specifically selected because previous experiments had shown that S-lactoylglutathione had little effect on anti-IgE-induced histamine release from her cells. S-Lactoylglutathione was prepared as described in Fig. 1.

The present findings implicate S-lactoylglutathione as a modulator of anti-IgE-induced histamine release and, as such, represent the first demonstration of an effect of this compound in any secretory system. In addition they are compatible with the general hypothesis that the function of the two glyoxalase enzymes is the regulation of S-lactoylglutathione levels. It is not yet known whether anti-IgE, the stimulus for histamine release, alters the activities of the glyoxalase enzymes and thereby increases S-lactoylglutathione levels in basophils. This is a definite possibility, however, as concanavalin A increases the activities of both glyoxalase enzymes in lymphocytes and polymorphonuclear leukocytes[10] and also causes histamine release from basophils through interaction with IgE[9]. The mechanism whereby S-lactoylglutathione potentiates histamine release is not clear. Because evidence has implicated S-lactoylglutathione in the process of microtubule assembly *in vitro*[5] while histamine release is a microtubule-dependent process[6,7], it is possible that it affects histamine release, in part, by promoting microtubule assembly. It seems unlikely, however, that this is its only mode of action as disruption of microtubules with colchicine does not inhibit release to as large an extent as phenylglyoxal[6,7]. Elucidation of the precise role(s) of S-lactoylglutathione in histamine release will require further study.

I thank Dr Robert Vince for his gift of PAL6-25-1 and Dr Lawrence M. Lichtenstein for carrying out the histamine assays. This work was supported in part by NIH grants AI00043 and AI11334.

The influence of thymus on the development of MHC restrictions exhibited by T-helper cells

IMMUNE functions depend largely on the activities of peripheral lymphocytes which have been 'processed' in the thymus (T cells). The best characterised activities of these cells, such as *in vitro* cytotoxicity and suppressor and helper capacities in adoptive immunisations seem to be mediated by distinct subpopulations. However, it has emerged that T cells of all subpopulations exhibit a dual recognition faculty, on the one hand, towards entities coded by the major histocompatibility gene complex (MHC) and on the other towards foreign antigens. Without appropriate MHC recognition 'foreignness' may not be noticed, giving rise in various functional assays to what has been termed MHC restriction. For example, in the mouse, T cells may lack cytotoxicity unless they have H–2 region gene products[1], in common with their target cells. T cells which 'help' in antibody responses can only do so fully if the B cells with which they are cooperating have similar I-region coding[2]. These various restrictions were thought to represent the need for interaction of like substances on cell surfaces perhaps to establish propinquity before any subsequent interactions could be initiated. Recently, however, it has been demonstrated[3,4] that irradiated bone marrow chimaeras of the type $A+B \rightarrow (A \times B)F_1$, possessed populations of T cells of A and B origin each of which was capable of interacting with B-cell populations of both A and B origin (A and B are used here purely as symbols for MHC-disparate mouse strains). Thus it seemed whatever the genetic determinacy of the cell, it could, when appropriately conditioned, establish reactions based on identity with either genetically similar or genetically different cells[2,5]. The exact nature of this conditioning began to emerge from experiments of Bevan[6] and Zinkernagel[7] who found that T cells from $(A \times B)F_1 \rightarrow A$ chimaeras could only kill target cells bearing A type MHC determinants, whilst no cytotoxicity towards B targets was possible. Comparable studies gave analogous results for helper T cells[8,9] and recently, it was shown that the events which seem to determine the pattern of H–2 restricted specifities of the T cells concerned with cytotoxicity occur within the thymus gland[7]. We now show that intrathymic conditioning also determines the restriction specificities of T cells involved in helping antibody production.

The experimental design (Table 1 legend) aimed to generate populations of F$_1$ T cells which had differentiated to their T-cell status within parental thymus grafts. In other studies it has been shown that both thymus lobes irradiated[10] as in the present series of experiments, and epithelial thymus grafts[11], are incapable of generating T cells of the graft genotype but are capable of acting as stageing houses for immigrant, unirradiated bone-marrow stem cells. From these and other studies it is a reasonable assumption that the majority of T cells in a thymectomised, irradiated, bone-marrow injected, thymus-grafted mouse such as those in the present studies, will have been processed by the (irradiated) thymus graft.

Thymic chimaeras were constructed using (C3H/He × BALB/c)F$_1$ recipients of irradiated thymus grafts. Three groups of experimental chimaeras were compared. One group received C3H/He (H–2^k), another BALB/c (H–2^d) and the third (C3H/He × BALB/c)F$_1$ thymus grafts. Helper function of spleen T cells from individual donors was then assessed on CBA (H–2^k) and BALB/c (H–2^d) B cells. (C3H/He × BALB/c)F$_1$ T cells which had matured through the influence of a C3H/He thymus tended to cooperate better with CBA B cells; those which had matured through a BALB/c thymus usually showed preference for cooperation with BALB/c B cells (Table 1). Those T cells which had differentiated through a (C3H/He × BALB/c)F$_1$ thymus were able to cooperate in all instances with both CBA and BALB/c B cells, perhaps with a slight bias towards CBA B cells. [Failure to cooperate efficiently with B cells bearing MHC specificities different to those of the thymus of maturation was unlikely to be the result of the 'wrong' haplotype markers on B cells eliciting nonspecific suppressors because in 10 thymic chimaeras tested, cooperation was always observed with (CBA × BALB/c)F$_1$ B cells whatever the restricted specificity of the helper population.]

Table 1 Thymus determines MHC restricted specificities of T-helper cells

Source of thymus graft		Total no. of anti-TNP PFC with the following B-cells.	
		CBA(H–2^k)	BALB/c(H–2^d)
Expt 1*			
C3H/He	Donor 1	1,676	43

	5	2,447	207
BALB/c	Donor 4	1,121	1,943
	5	430	419
(C3H/He × BALB/c)F$_1$	Donor 3	1,804	580
No T cells		567	30
Expt 4			
C3H/He	Donor 6	1,742	320
	7	4,346	321
BALB/c	Donor 6	789	1,681
(C3H/He × BALB/c)F$_1$	Donor 4	2,047	1,646
No T cells		324	437

Thymic chimaeras were constructed as follows:- (C3H/He × BALB/c)F$_1$ mice were thymectomised at 6 weeks of age. One month after thymectomy the mice were irradiated with 875 R and reconstituted with (C3H/He × BALB/c)F$_1$ bone marrow (approximately 5×10^6 bone-marrow cells per recipient) to produce relatively T cell-free (AT × BM) mice. Fifteen days later thymus lobes were obtained from newborn mice, irradiated *in vitro* with 600 R and transplanted under the kidney capsule of each AT × BM recipient, one thymus lobe each. This procedure was designed to provide an environment for the maturation of host T cells without allowing any maturation of thymus-graft donor cells. Seven weeks later all recipients were primed with 250 μg keyhole limpet haemocyanin (KLH) in Freund's complete adjuvant (FCA); after a further 3 weeks all mice were boosted with 100 μg of soluble KLH and after 8–10 days the animals were killed and their spleens taken as a source of T-helper cells for *in vitro* experiments. T-helper function was assessed in an *in vitro* microculture system as previously described[5,8]. In brief, T cells were purified by passage of spleen cells through nylon wool. Red cells were removed by treatment with ammonium chloride and the remaining (T) cells treated at 37°C for 20 min with 25 μg ml^{-1} mitomycin C to eliminate the possibility of antibody production by any residual B cells. 'B cells' were spleen cells from TNP-OVA primed CBA or BALB/c mice, and were treated with anti-Thy 1.2 serum and complement. Helper T cells were incubated for 5 days with both BALB/c and CBA B cells in the presence of antigen (0.1–0.3 μgml^{-1} TNP–KLH). Total direct and indirect PFC to TNP coupled donkey erythrocytes were then determined from 28–30 microculture wells.

* The efficiencies of responses of BALB/c and CBA B-cells were compared in expts 1 and 2 by the addition of primed T cells of pools of (C3H/He × BALB/c)F$_1$ mice. In expt 1 BALB/c B cells gave 2,818 PFC (in 30 wells) while CBA B cells gave 2,215 PFC. In expt 2 BALB/c B cells gave 2,469 PFC while CBA B cells gave 1,831 PFC.

0028–0836/79/0277—0137$01.00

It is interesting that (CBA × BALB/c)F_1 T cells which had matured in a BALB/c thymus should in most cases have cooperated with CBA B cells to some extent. This 'noise' in such MHC restriction experiments is not uncommon in our hands and was repeatedly observed in situations where BALB/c T cells, whatever the source, have been tested for helper function with CBA B cells. As suggested previously[8] this may represent an interesting one-way cross reaction between BALB/c and CBA MHC associated specificities.

This result is fully compatible with and clarifies previous studies with bone marrow chimaeric mice. Thus: (1) Totally allogeneic ($A \rightarrow B$) chimaeras make poor antibody responses to thymus dependent antigens[12]. In this case A T cells develop in a B thymus and thus cooperate inefficiently with A B cells. (2) T cells from $(A \times B)F_1 \rightarrow A$ chimaeras cooperate with A B cells only[8,9], for they will have matured in an A thymus. (3) T cells from $A + B \rightarrow (A \times B)F_1$ double chimaeras cooperate with both A and B B cells[3,4] for they have developed in an $(A \times B)F_1$ thymus. (4) T cells from $A \rightarrow (A \times B)F_1$ single chimaeras have the potential for cooperation with B B cells[8], again as a result of developing in an $(A \times B)F_1$ thymus.

It is also of interest that in the helper T-cell system it is the I region[2] which determines the observed MHC restrictions, for it is this region which also codes for MHC-linked Ir genes. It is possible to think that MHC restriction and MHC-linked Ir genes are but two faces of the same coin[13], and indeed recent evidence lends support to this view, in studies where it was shown that MHC gene products (presumably in the thymus) can determine the T-cell repertoire to extrinsic (nominal) antigens[14].

These results with helper T cells fulfil what could be predicted from the original findings of Zinkernagel *et al.*[7] with cytotoxic T cells; and reemphasise the point that MHC gene products are involved in the process of differentiation within the thymus.

Localisation of intestinal gastrin in a distinct endocrine cell type

GASTRIN extracted from human intestine has two main molecular forms, little (G17) and big (G34) gastrins[1]. Both these peptides are also found in antral tissue although their relative proportions differ, G17 being the major component in antral tissue and G34 that in intestinal tissue[1]. The endocrine cell associated with the production of the immunoreactive gastrin found in the antral tissue is the ultrastructurally classified G cell[2]. The cellular origin of the immunoreactive gastrin extracted from the intestinal tissue has not been determined. The presence of cholecystokinin (CCK) peptides[3,4], closely related to gastrin and sharing with it a C-terminal pentapeptide sequence (see Fig. 1), makes the specific immunological detection of both gastrin and CCK dependent on the use of well characterised and highly specific antibodies. We report here the finding that intestinal gastrin originates in a type of cell totally distinct from the I cell which has recently been identified as the source of CCK[5].

To provide conclusive evidence we have used the semi-thin/thin sectioning method[6] with four different antisera. Each antiserum was specific for a different region of the peptide molecules, as shown in Fig. 1. G5 is a C-terminal-directed antiserum capable of detecting both gastrin and CCK[7]. 1295 Is directed to the N-terminal region of G17 and detects principally little gastrin[8]. L33 is directed to the N-terminal region of big gastrin, G34, and detects the G34 form of gastrin[9]. Z58 was raised to a synthetic peptide with the 9–20 amino acid sequence of CCK; the antibodies detect only CCK from the series of homologous peptides (see Fig. 1). None of the antisera showed significant binding to any other available gut peptide, including secretin, vasoactive intestinal polypeptide, gastric inhibitory polypeptide, neurotensin, motilin, pancreatic polypeptide, somatostatin, glucagon, substance P and bombesin.

Semi-thin (800 nm) sections of human antrum, duodenum and jejunum, fixed in purified glutaraldehyde and embedded in resin, were stained by the indirect immunofluorescence

method[10]. Serial sections were incubated with 1295 (1:300), G5 (1:100), L33 (1:100) and Z58 (1:200) overnight at 4 °C. A second layer of fluoresceinisothiocyanate (FITC)-conjugated antirabbit globulin was applied for 1 h at room temperature. The specificity of the immunostaining was established by previous incubation with purified peptides as detailed in Table 1. The results of the tissue controls confirm the data already available on the specificity of the antisera. Additional controls were the incubation of serial semi-thin sections with normal rabbit serum (1:100) and FITC-conjugate alone, neither of which showed any positive cells.

The results of the immunostaining on the semi-thin (800 nm) sections of antral tissue showed that L33, 1295 and G5 all stained identical cells. These cells were then identified on the serial thin (60 nm) sections by means of easily located landmarks, such as mucin cells, which are visible in both semi-thin and thin sections. The ultrastructural appearance of the cells identified in this way was that of typical G cells with secretory granules ranging from large (350 nm) and electronlucent to small (190 nm) and electron dense. Z58 was negative on antral tissue as expected.

The semi-thin sections of duodenum and jejunum gave the following results. L33 and 1295 stained identical cells (Fig. 2*a*, *b*), Z58 stained a completely different population of cells (Fig. 2*d*), and G5 stained both cell populations (Fig. 2*c*).

As Z58 is specific for CCK and G5 is capable of binding to both CCK and gastrin, we conclude that the cells stained by both these antisera correspond to the I cells already characterised as the source of CCK[5]. This was confirmed by the appearance of the cells at an ultrastructural level. The cells stained by L33, 1295 and G5 must, by virtue of the specificity of the L33 and 1295 antisera, contain the immunoreactive gastrin present in the intestine. On serial thin sections these cells were found to be of a single type, with secretory granules which were small, round and electron dense (Fig. 3*a*–*c*). Electron micrographs of these cells were used to measure the secretory granules; 650 granules from 12 cells were measured, giving a mean diameter of 175 ± 24 nm (mean ± s.d.). When the measurements were corrected for sectioning artefact[11], the final value for the mean diameter was 220 ± 20 nm.

Clearly, the cells containing gastrin in the intestine are of a different morphological type from the G cells of the antral mucosa. They totally lack the large electronlucent granules that are so characteristic of the antral (GA) cells. Recent work has shown that the antral mucosa contains equimolar amounts of G17 and the N-terminal fragment left after cleavage of G34 to G17 (ref. 9), in addition to smaller quantities of G34 itself. It is possible that the large electronlucent granules in the antral (GA) cells contain the products of the enzymatic cleavage of G34, whereas the small granules present in the same cells contain mainly unaltered G34. Thus, the granules of the intestinal gastrin (GI) cells could correspond to these small G-cell granules

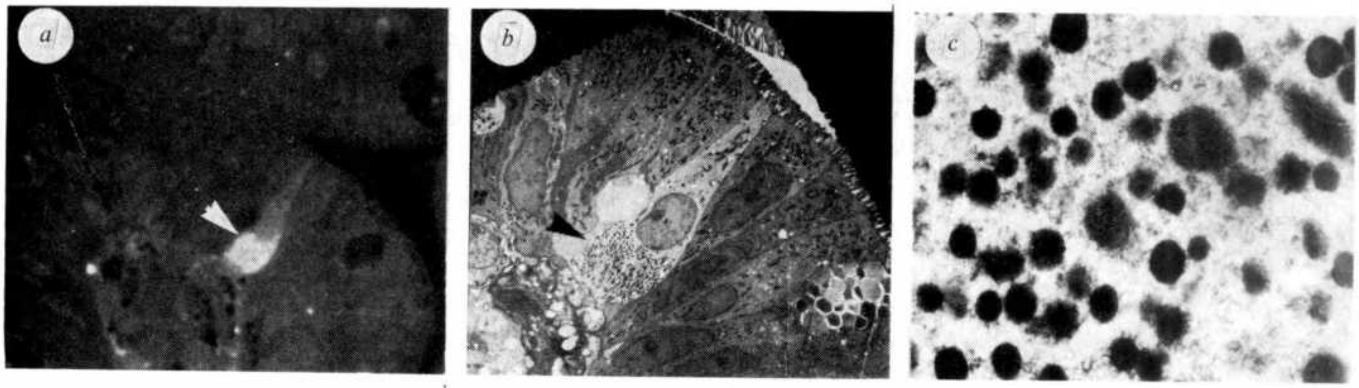

Fig. 3 *a*, 800-nm section prepared as described in Fig. 2, stained with 1295 (1:300), the N-terminal G17 antiserum. The arrow indicates the positive endocrine cell. ×1,500. *b*, Serial thin (60 nm) section showing the same endocrine cell. Note the connection to the gut lumen by microvilli and the grouping of the secretory granules close to the basement membrane. ×2,000. *c*, High magnification electronmicrograph of the endocrine cell to show details of the secretory granules. ×27,000.

Table 1 Specificity of immunostaining

Antisera (dilution)	Absorption	Peptides (nM) Gastrin 17	Gastrin 34	CCK octapeptide	CCK 1–33	Area of gut
G5 (1:100)	Amount	0 3	ND	1	2	Antrum Duodenum Jejunum
	Result	—		—	—	
1295 (1:300)	Amount	1	5	10	10	Antrum Duodenum Jejunum
	Result	—	+++	+++	+++	
L33 (1.100)	Amount	10	2.5	10	10	Antrum Duodenum Jejunum
	Result	+++	—	+++	+++	
Z58 (1:200)	Amount	10	ND	10	1	Duodenum Jejunum
	Result	+++		+++	—	

All absorptions were carried out by pre-incubation of the diluted antisera with the peptides overnight at 4 °C before staining the tissue. +++, Positive immunostaining, –, no immunostaining; ND, not done; in this case the gastrin 34 peptide was only available in extremely small quantities, therefore only essential absorptions were undertaken.

and these may also contain mainly unaltered G34, which is the predominant molecular form of gastrin in the intestine.

Information from the study of tissue cultures carried out on gastrinoma cells[12] can be interpreted in the light of these findings. The cells in the original tumour contained the characteristic large electronlucent granules of G-cell type and the majority of the extracted gastrin was G17. After 2 weeks of culture the secretory granules had become progressively smaller and the content of the culture was predominantly G34.

The cells which we have identified as the origin of intestinal gastrin have probably been included in previous classifications as belonging to the ubiquitous D_1 cell category. These cells have been defined as containing small (140–190 nm) round granules, with moderate osmiophilia and a closely applied membrane. The retention of the D_1 nomenclature for the duodenal/jejunal cells containing gastrin would be confusing due to the widespread distribution of cells corresponding to the above description[13]. As the new variety of gastrin-containing cells is confined to the intestinal mucosa, we propose the name GI for these cells, denoting their intestinal origin, as distinct from the GA cells which are mostly confined to the antral region of the stomach. This is in keeping with the move towards a functional rather than morphological classification initiated in the Lausanne revision of the original Wiesbaden (1969) endocrine cell classification. Two new cell types have now been named after their peptide product, the N or neurotensin-containing cell[13] and the PP or pancreatic polypeptide-containing cell[13].

In previous classifications a functional emphasis was not possible because there was insufficient evidence about the peptide products of the various cell types. The widely accepted semi-thin/thin technique, in combination with technical advances in antibody production and improved immunocytochemical methods have made a functional classification possible.

This work was carried out with the aid of grants from the MRC and Cancer Research Campaign. We thank Dr J. H. Walsh for the 1295 antiserum, Dr G. J. Dockray for a sample of his purified L33 antiserum, Professor V. Mutt for the purified CCK peptide, and Professor R. A. Gregory for purified G34 peptide. G5 antibodies were raised by Dr S. R. Bloom.

Identification of the neuritogen for experimental allergic neuritis

EXPERIMENTAL ALLERGIC NEURITIS (EAN) is a model of human acute inflammatory polyneuropathy, Guillain–Barré syndrome. It can be produced in several species of laboratory animal by immunisation with homologous or heterologous peripheral nerve emulsified in Freund's complete adjuvant[1,2]. After about two weeks the animals may develop signs varying from ataxia to paralysis and death. EAN has been produced using crude acid extracts of peripheral nerve[3,4], but investigations into the neuritogenic properties of the component proteins of peripheral nerve myelin have yielded inconclusive results[5–10]. In experimental allergic encephalomyelitis (EAE), the central nervous system (CNS) counterpart of EAN, the encephalitogenic antigen has been shown to be a CNS myelin basic protein of molecular weight 18,000 (ref. 11). The three major proteins of peripheral nerve myelin, which together account for about 75% of the myelin protein, are usually referred to as P_0, P_1 and P_2 (ref. 12). P_0 is a glycoprotein of molecular weight 30,000 and P_1 and P_2 are both basic proteins with molecular weights of 18,000 and 12,000–14,000, respectively[12–13]. We describe here a reliable method for producing severe EAN in inbred Lewis rats with bovine intradural root material, and show that intact P_2, the major basic protein of peripheral nerve myelin, is the responsible neuritogen.

Bovine intradural root was obtained within 30 min of death and myelin was prepared from this by sucrose density centrifugation[15]. The crude acid extract was prepared by incubating myelin in 30 mM HCl for 16 h and collecting the supernatant

Table 1 Production of EAN in Lewis rats with whole myelin and pure P_2 from bovine intradural root

					Histological disease		
					EAN		EAE
	Dose	Day of	Clinical disease				
Antigen	(mg per animal)	onset	Incidence	Mean score	Incidence	Mean score	Incidence
Saline	—	—	0/2	—	0/2	—	0/2
FCA	—	—	0/3	—	0/3	—	0/3
Myelin (5)	2.5	12.0	25/25	2.5	24/24	2.6	0/24
Acid extract (2)	0.25	12.9	8/9	2.0	9/9	2.4	0/9
P_2 (2)	0 25	12.5	10/10	2.1	10/10	2.6	0/10

All samples except saline and adjuvant controls were emulsified in an equal volume of Freund's complete adjuvant (FCA) containing 10 mg ml^{-1} *Mycobacterium tuberculosis* H37RA (Difco). The numbers in parentheses refer to the number of individual experiments carried out; a different antigen preparation was used for each. For scoring the clinical disease, the animals were assessed daily after day 7 according to the scale: 0 = normal; 1 = limp tail; 2 = mild or moderate paraparesis; 3 = severe paraparesis, tetraparesis or paraplegia. Scoring of histological disease were. 0 = normal or equivocal lesions, 1 = mild, 2 = moderate and 3 = severe, invasion of inflammatory cells.

after centrifugation. The basic protein, P_2, was purified from this crude extract by ion exchange[7] and gel exclusion[16] chromatography. All steps were carried out at 4 °C in the presence of 1 mM mercaptoethanol; 5 g of lyophilised myelin yielded approximately 30 mg of P_2. This was judged to be pure by the presence of a single band on SDS-polyacrylamide electrophoresis, similarity of amino acid content to that in previous reports (especially the absence of histidine)[13,14], and the absence of ganglioside.

Male inbred Lewis rats (175–225 g) were given two subcutaneous injections of 50 μl emulsion, one just proximal to each fore-footpad, and were weighed and examined daily. All remaining animals were killed on day 21. Longitudinal sections of each sciatic nerve, the cervical and thoracic cord and brain, and six transverse sections of the lumbosacral cord and cauda equina from each animal were stained with haematoxylin and eosin and examined by light microscopy.

Preliminary experiments revealed bovine intradural root to be the best starting material and the inbred Lewis rat to be the most convenient species. In five separate experiments (Table 1), each with a different preparation of bovine intradural root myelin, moderate or severe clinical and histological EAN was always produced and the CNS showed no evidence of cellular infiltration. The lack of CNS involvement when using bovine peripheral myelin agrees with a recent report[17]. Clinical signs first appeared in some animals on day 11, with a mean onset of 12.0 d. This was accompanied by a weight loss to 75% of the starting weight.

The acid extract was then shown to be neuritogenic at a dose (0.25 mg per animal) which was calculated to contain a similar amount of P_2 as 2.5 mg whole myelin[12]. Finally, pure P_2 was shown to be neuritogenic at a dose of 0.25 mg. No CNS involvement was found in any of the animals treated with either the acid extract or pure P_2.

Of the two basic proteins in peripheral myelin, P_1 has been shown to be the same as the encephalitogenic basic protein in the rabbit sciatic nerve[18], and this is likely to be the same for other species. Thus, attention has focused on the other basic protein, P_2, which may be specific to peripheral nerve myelin[13]. Previous attempts to induce EAN with a pure isolated protein have used bovine intradural root BF (same as P_2) in the guinea pig[6], bovine intradural root P_2 in the rabbit[7] and rabbit sciatic nerve P_2 in the monkey and guinea pig[5]. All but the last were unsuccessful, and this result was later withdrawn[7] with the suggestion that isolation might lead to an alteration in the considerable secondary structure of P_2. In confirmation of this, Brostoff *et al*[10] have reported that a cyanogen bromide peptide of P_2, but not whole P_2, was neuritogenic. In addition, Abramsky *et al.*[8,9] have isolated a basic protein of molecular weight 14,000 from human and bovine sciatic nerves which they reported to be neuritogenic. In the first report[8] this protein, known as P_1L, was claimed to differ from all known myelin proteins, whereas in the latter[9] it was thought to be the same as P_2. In both reports, however, the disease produced was very mild, with an incidence as low as 50% in some experiments. Moreover, others have suggested that the reported amino acid content of P_1L indicates contamination with other proteins, especially P_1 (ref. 14).

In the present study, a 100% incidence of pure EAN without EAE has been produced by the use of bovine intradural root P_2 in the inbred Lewis rat, a combination not previously reported. Thus, in contrast to the experience of others[10], we have been able to isolate P_2 in a form which is still neuritogenic. Overall, the clinical disease produced by the pure neuritogen was slightly less severe than that produced by whole myelin, but, nevertheless, several animals developed the maximum score on our scale. A possible reason for the lack of success of previous authors, apart from the combination of tissue and recipient, may be their predominant use of the guinea pig[4–9], because this species has been shown to possess very little P_2 in its peripheral myelin[12]. Thus, guinea pigs immunised with peripheral myelin basic proteins have been reported to remain unaffected[6,7], develop EAE[5] or a low incidence of a very mild EAN[9]. In our preliminary investigation with the guinea pig, we found that bovine intradural root produced only EAE and not EAN

Now that we have clearly identified the neuritogen involved in the animal model of Guillain–Barré syndrome, we intend to extend our study to look for evidence of sensitisation to P_2 in the human disease.

We thank Dr N. A. Gregson for advice, Mr A. R. Salliss for histological assistance, and the MRC for financial support.

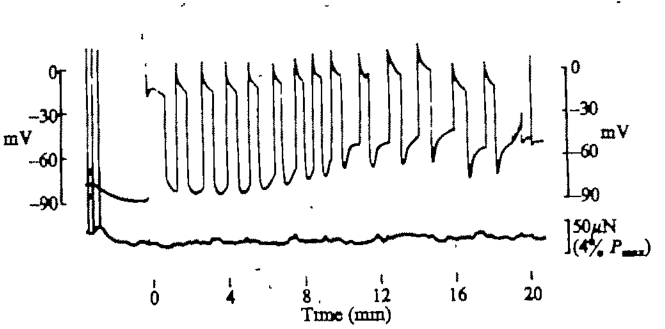
Are cardiac muscle cells 'skinned' by EGTA or EDTA?

KNOWLEDGE of the processes involved in the contraction of skeletal muscle fibres has been greatly advanced by study of the 'skinned' fibre preparation. Here the sarcolemma is peeled off, giving access to the intracellular organelles unhampered by an intervening cell membrane. The small size of cardiac muscle cells had seemed to preclude the use of this technique, and so interest has been shown in a 'chemical' method for 'skinning' heart cells, which involves exposing the muscle to EGTA and EDTA (ref. 1). However, this paper questions the effectiveness of the EDTA/EGTA skinning methods, reporting that tension production in fully treated cells is $[\mathrm{Na}]_o$ dependent, and that the cells can support resting and action potentials in low $[\mathrm{K}]_o$-'skinning' media. It is concluded that both the high Ca-sensitivity and low membrane potential of EGTA/EDTA-treated cells occur without radical impairment of the sarcolemmal permeability barrier. An alternative explanation for the high sensitivity to extracellular calcium is presented which involves the Ca–Na exchange mechanism.

Treating cardiac muscle with divalent cation chelators such as EDTA and EGTA is reported to produce a 'high permeability state' after 12–20 min exposure to a medium which typically includes KCl, ATP and a buffer, in addition to the chelator[1–6]. The evidence that this procedure makes the heart cell membrane 'highly permeable to the calcium buffer system' (ref. 1) depends heavily on two principle observations: first, the treated cells have a very low resting potential, suggesting that the sarcolemma has become freely permeable to small ions[1,4,5], and second, that tension can be induced by Ca^{2+} at micromolar levels. Mechanical activity at these low concentrations is normally associated with the activation of isolated contractile proteins or of skeletal fibres skinned by more direct methods[1–6]. The EDTA/EGTA method, or a variation of it, has subsequently been applied to several cardiac tissues, smooth muscle[7] and skeletal muscle[8]. However, recent studies of frog heart[9,10] have suggested that the two above characteristics are not unique to skinned cells and, therefore, are not unequivocally indicative of 'skinning'.

In these previous experiments, and those to be reported here, EGTA- and EDTA-containing solutions have been applied to fine atrial and ventricular trabeculae of frog heart by rapid superfusion. The results may be summarised thus. First, protracted action potentials are produced in EGTA-Ringer solution; these can arise spontaneously and eventually last up to a few minutes. Unless observed by continuous recording from one cell, this behaviour can give the appearance of a full depolarisation of the cell. However, even in preparations exposed to EGTA for over an hour the action potential can be curtailed by acetylcholine (ACh) or divalent cations[9]. The resting potential between the long action potentials is well maintained and, by inference, the cell membrane is still an effective permeability barrier. The effects also occur with EDTA and are more marked; spontaneous activity is common and action potential prolongation even greater. Figure 1 shows a typical record where the exposure to EDTA was started with the preparation already in the presence of ACh. ACh induces hyperpolarisation. Addition of EDTA rapidly evokes a spontaneous train of long action potentials which is sustained over 15 min. Restoration of Ca^{2+} returns electrical (and eventually mechanical) activity to near normal.

Fig. 1 Electrical activity in EDTA-containing solutions. Membrane potential (upper trace) and tension (lower trace) from a superfused frog ventricle trabeculum (diameter ~200 µm, length 2 mm). On addition of acetylcholine (10^{-5} M) to the Ringer solution (see ref. 9) stimulation was halted. Removing Ca and adding 3 mM EDTA induced spontaneous activity which persisted until EDTA was removed and Ca restored (after 17 min). A stimulus (at 20 min) produced an action potential of near-normal duration. Temperature 20 °C.



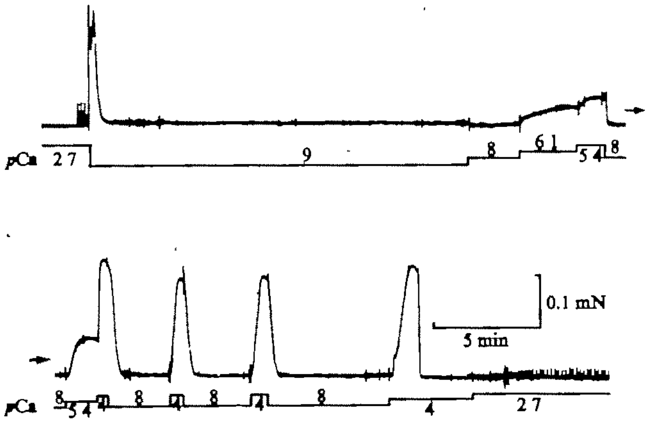


Fig. 2 Tension responses of a superfused frog atrial trabeculum (diameter ~100 µm, length 1.5 mm). Changing from Ringer's solution (pCa 2.7 = 2 mM) to Winegrad's 'disruption' medium (mM; KCl 120, $\mathrm{Na_2ATP}$ 5, Tris 20, EDTA 5, pCa ~9) induced a contracture. pCa values of less than 9 indicate that the 'activating' solution (mM; KCl 120, $\mathrm{Na_2ATP}$ 5, Tris 20, $\mathrm{MgCl_2}$ 1, EGTA 5, Ca 0–5) was used. Halfway through the final exposure to pCa 4, the 'activating' solution was substituted by Ringer's solution at the same pCa value. Temperature 20 °C, pH 7.00

The second and, apparently for most authors it seems, the major criterion of the 'high-permeability state', namely high sensitivity to calcium, can also be displayed by cardiac cells without skinning them. Frog atrial trabeculae exposed to low sodium concentrations (with and without EGTA) produce half-maximal contracture tension at a $[\mathrm{Ca}^{2+}]$ of $\sim 2\times 10^{-7}$ M with a normal resting membrane potential[10]. This finding has been extended to frog ventricle where half-maximum tension in identical conditions occurs at 1.2 (±s.d., 0.5) $\times 10^{-6}$ M Ca^{2+} ($n = 6$). Relaxation is very slow in these conditions ($t_{1/2}$ of the order of 250 s at pCa 6 compared with about 10 s at pCa 4–2)[10,14] and can give the appearance of a tonic rather than a phasic response. Until relaxation is completed, tension steps can be induced by pCa changes.

As both criteria for skinning fail to distinguish clearly between hypothetical skinned cells and those described above which are patently unskinned, it must be asked if cells exposed to the full EDTA and EGTA 'skinning' treatment are really skinned at all.

To identify whether the preparation undergoes a qualitative change in Winegrad's 'disruption' medium, the constituents of this medium were tested in various permutations. In summary, the high permeability state, judged on the development of high Ca sensitivity (repeatable step-wise responses to pCa changes), loss of membrane potential (except obviously in K-rich media) or production of rigor (high Ca, ATP-free media), could not be demonstrated even with the combination of EDTA or EGTA (up to 10 mM), high $[\mathrm{K}^+]$, low $[\mathrm{Na}^+]$ and Tris buffer. However,

0028-0836/79/0277–0142$01.00

inclusion of ATP, which is present in Winegrad's full disruption medium, did produce a qualitative change in contractile behaviour.

If pCa steps were made after 20 min exposure of a frog ventricle or auricle trabeculum to EDTA or EGTA ($p\text{Ca} \geq 8$, see legend to Fig. 2), then tension steps could be induced in the range of pCa 7–4. However, there are at least four clear indications that these preparations are not skinned. (1) Spontaneous relaxation occurs, although at a very slow rate; (2) peak contracture tension at a given pCa falls with the duration of the exposure to the 'skinning' medium: the highest Ca sensitivity in these preparations develops within a minute but reaches a lower steady level after about 20 min; (3) rapid, full relaxation is produced when Ringer's solution is restored; (4) In an ATP + EGTA (or EDTA) Ringer solution ($p\text{Ca} > 8$), as before, long-lasting ACh-sensitive action potentials can be recorded for over an hour.

The third point is illustrated in Fig. 2. If these cells were in fact skinned, then restoring Ringer's solution (removing MgATP) while the muscle is contracted should, if anything, induce rigor[11]. Similar, though much slower, effects are visible in Winegrad's published records (ref. 1, Fig. 1). He interpreted this as due to a 'healing over' of the cell membrane at the raised calcium level. This argument can be discounted, as no relaxation occurs even at $p\text{Ca} < 2$ (see, for example, ref. 12, Figs 1, 2, 4) and relaxation occurs even without altering pCa (Fig. 2).

The relaxation produced by restoring Ringer's solution is primarily the result of raising the sodium concentration. This was shown by investigating the effect of $[\text{Na}^+]$ on contracture strength in preparations that would otherwise be judged 'highly permeable'. Figure 3 shows the effect of $[\text{Na}^+]$ from 6.6 to 63 mM on contracture strength at constant pCa. Three typical tension reponses are shown on the right, from which it is clear that peak force is reduced as sodium concentration increases (note that $[\text{K}^+]$ is constant and tonicity maintained with Tris). Results from one preparation are plotted on the left. The steep dependence of contractile strength at constant pCa on $[\text{Na}^+]$ is not characteristic of skinned muscle but is reminiscent of responses to simple low-sodium media (ref. 10, Fig. 4). An expression derived in that paper (Eq. A6) relates contracture strength to $[\text{Na}^+]_o$ at constant $[\text{Ca}^{2+}]$, and by choosing a suitable value for $K_{\text{Na}}^{\text{app}}$ (which alters the position but not the shape of the curve) a good fit is obtained. The curve is shifted to the right on the Na axis at lower pCa values. This expression relates to the behaviour of a Na–Ca exchange system in the sarcolemma of frog heart. The results indicate that these supposedly skinned cells are not skinned at all, but rather that the tension reponses observed result from the operation of the Ca–Na exchange system whose activity has been modified by depolarisation (120 mM K^+) and perhaps more importantly, by extracellular ATP.

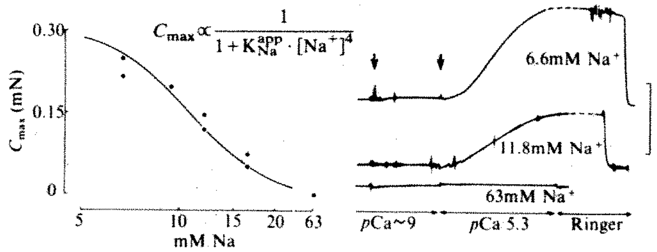

Fig. 3 Right: tension records obtained after a 2-min exposure to the 'disruption' solution (see Fig. 2), at which time Ca-sensitivity is maximal. At the first arrow, the 'activating' solution was applied (pCa ~8, Na_2ATP 3.3 mM and Tris 127 mM otherwise as in Fig. 2, that is, hypertonic). At the second arrow, 1 min later, the pCa was reduced to 5.3 with $[\text{Na}]_o$ varied by substituting NaCl for Tris-Cl. Finally, normal Ringer's was restored. Left: results from one experiment of the type shown on the right relating peak contracture tension ($C_{\max}$) to $[\text{Na}^+]_o$. The curve was drawn according to the equation and scaled to maximum possible tension taken as that observed in a 120 mM KCl, 0 mM NaCl solution[11]. The value of $K_{\text{Na}}^{\text{app}}$ in this case was $1.34 \times 10^8\ \text{M}^{-4}$. Calibration bar = 0.15 mN, temperature 20 °C, pH 7.00. (*Rana esculenta.*)

Frog heart is not rendered 'highly permeable' by Winegrad's method. Whether a similar criticism may be levelled at results obtained with other cardiac and non-cardiac tissues using this technique[2,4,7,8] is open to speculation, although morphological studies of human skeletal muscle are reported to have shown disruption of the sarcolemma[8]. Long-lasting action potentials in EDTA have been reported for mammalian cardiac tissue[13]. The results reported here clearly indicate that the two properties of high calcium sensitivity and low resting potential are not sufficient indices of successful skinning. It seems that only the elegant and painstaking microdissection techniques of Fabiato and Fabiato[15] ensure that a cardiac cell can be skinned while leaving the sarcoplasmic reticulum and mitochondria intact.

Activation of adenylate cyclase by vanadate

VANADATE has been identified as a potent inhibitor of (Na,K)ATPases[1,2]. The (Na,K)ATPase of dog kidney is inhibited 50% by 40 nM sodium orthovanadate (Na_2VO_4) in optimal conditions (28 mM Mg^{2+})[2]. As vanadate was originally identified as an inhibitor in muscle-derived ATP preparations[2] and in equine and rabbit skeletal muscles, it has been suggested as endogenous regulator of (Na,K)ATPase[2–4]. We have tried to use vanadate as a tool to inhibit ATPases in adenylate cyclase studies when working at low ATP concentrations. We report here that vanadate causes marked stimulation of adenylate cyclase activity in membranes isolated from rat fat cells and produces maximal activation even in the absence of hormones.

Plasma membranes of isolated fat cells were prepared from epididymal adipose tissue of male Sprague-Dawley rats (160–220 g). The preparation followed essentially the method of McKeel and Jarett[5]. The determination of adenylate cyclase was carried out as described previously[6] using the protein-binding method of Gilman[7]. The assay contained in a total volume of 100 µl: 1 mM ATP, 20 mM MgCl_2, 40 mM Tris-HCl, pH 7.4, 5 mM creatine phosphate, 10 µg creatine kinase (25 units per mg) and 20 µg bovine serum albumin. The reaction mixture was preincubated for 5 min at 37 °C and the reaction started by addition of freshly thawed plasma membranes (4–8 µg per test tube). For blank values, heat-inactivated membranes were added to the reaction mixture. The reaction was stopped after 10 min incubation at 37 °C by addition of 1 ml of ice-cold

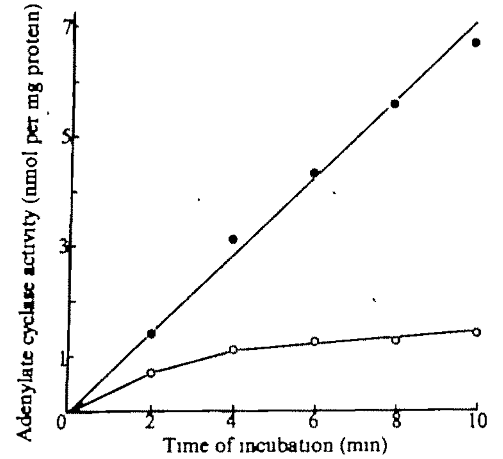

Fig. 1 Time course of adenylate cyclase activation by vanadate. Purified plasma membranes were isolated from rat fat cells by a previously described method[5]. Fat cell membranes (4.4 μg of membrane protein per 100 μl) were incubated at 37 °C in a medium containing 1 mM ATP with an ATP-regenerating system, 20 mM $MgCl_2$, 0.2% bovine serum albumin and 40 mM Tris-HCl buffer, pH 7.4. Activity was assayed without (○) and with 1 mM sodium vanadate (●). Values are means of triplicate determinations.

50 mM sodium acetate buffer, pH 4.0. Cyclic AMP was determined after 60-fold dilution of the samples. In these conditions, vanadate up to a concentration of 1 mM did not interfere with the assay procedure. Compounds used were anhydrous sodium vanadate ($NaVO_3$) and sodium fluoride (both Merck Darmstadt), theophylline (Boehringer Ingelheim), 1-noradrenaline-HCl (Fluka), guanylyl imidodiphosphate (GppNHp) and ATP (both Boehringer Mannheim).

Figure 1 shows a typical effect of sodium vanadate on the time course of adenylate cyclase activity in purified plasma membranes from rat fat cells. At a concentration of 1 mM, vanadate elicited an immediate stimulatory effect on enzyme activity which was linear up to 10 min. The increase of basal activity by vanadate was twofold after 2 min and more than fourfold after 10 min of incubation, the difference being due to a nonlinear time course of basal activity.

As can be seen from Fig. 2, the stimulatory effect of sodium vanadate was concentration dependent. A significant increase of cyclase activity was observed even with 10 μM vanadate. Similar dose–response curves were obtained with ammonium vanadate (NH_4VO_3). Concentrations higher than 1 mM vanadate have not been tested.

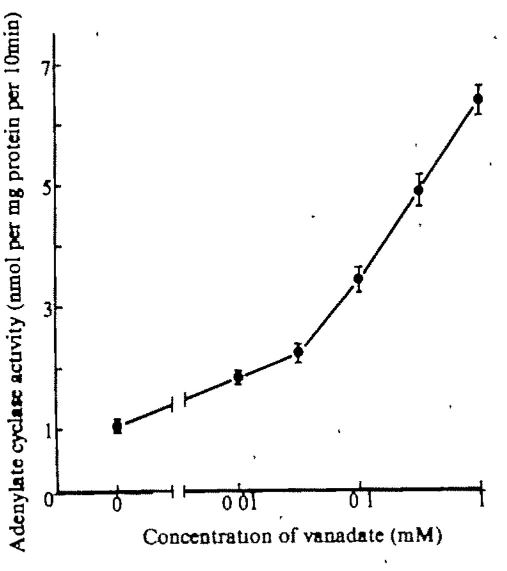

Fig. 2 Concentration dependence of vanadate stimulation of fat cell adenylate cyclase activity. Fat cell membranes were incubated as described in the legend to Fig. 1. Values are means ± s.e.m. of triplicate determinations.

The effect of vanadate on adenylate cyclase activity was further studied in the presence of a phosphodiesterase inhibitor and various stimulators of adenylate cyclase (Table 1). In the presence of theophylline, which itself had only a marginal effect on basal activity, the stimulatory effect of vanadate remained unchanged. Thus, it seems unlikely that vanadate might act as a phosphodiesterase inhibitor of a residual phosphodiesterase activity. Furthermore, vanadate in concentrations up to 1 mM had no effect on the activity of soluble and particulate cyclic AMP phosphodiesterases of rat fat cells (data not shown). The effect of 10 μM noradrenaline was further increased by addition of vanadate, but the effects of the two agents were not additive. The activity obtained with NaF plus vanadate was somewhat lower than that with NaF alone. Vanadate increased the effect of a low concentration of GppNHp (0.1 μM), but had no additional effect on a higher GppNHp concentration (1 μM).

As it is a potent inhibitor of (Na,K)ATPase activity[1,2], it seemed possible that vanadate might increase cyclase activity by preserving ATP as substrate for adenylate cyclase. However, cyclase activation by vanadate was independent of the concentration of ATP, tested in the range 1 μM–1 mM (data not shown). In addition, the ATP-regenerating system used in the present study effectively preserved the ATP concentration even at concentrations lower than 1 mM (ref. 6).

Table 1 Effect of vanadate on adenylate cyclase activity of rat fat cell membranes in the presence of theophylline or various stimulators of adenylate cyclase

Additions	Control	1 mM vanadate
None	1.04±0.04	6.43±0.25
Theophylline, 1 mM	1.20±0.01	6.38±0.22
Noradrenaline, 10 μM	2.05±0.03	6.77±0.49
NaF, 3 mM	13.28±0.76	11.89±0.10
GppNHp, 0 1 μM	3.05±0.24	5.89±0.18
GppNHp, 1 μM	7.95±0.16	8.13±0.10

Fat cell membranes (4 4 μg of membrane protein per 100 μl) were incubated for 10 min at 37 °C in a medium containing 1 mM ATP with an ATP-regenerating system, 20 mM $MgCl_2$, 0.2% bovine serum albumin and 40 mM Tris-HCl buffer, pH 7.4. Each experiment was run in triplicate, values are means±s.e.m.

Another hypothetical explanation for a mechanism of action of vanadate might be that in addition to its inhibitory effect on (Na,K)ATPases, it may affect other nucleoside triphosphatases and cause activation of adenylate cyclase by inhibiting a GTPase associated with the guanylnucleotide binding protein. It has been suggested that the guanylnucleotide binding protein of the adenylate cyclase system plays a dual role[8]; in the presence of hormone plus GTP it activates the adenylate cyclase, but also functions in the hydrolysis of bound GTP and thus terminates the activation. The latter reaction has been referred to as the turn-off GTPase reaction[8]. Any decrease in the rate of hydrolysis of GTP at the regulatory site would maintain more of the enzyme at the active state. A reduction of GTP hydrolysis has been proposed as the basis for increased adenylate cyclase activity after cholera toxin treatment[9]. Furthermore an inhibition of catecholamine-stimulated GTPases by cholera toxin and an enhancement of GTP-dependent adenylate cyclase activity have recently been observed in turkey erythrocyte membranes[8]. Experiments are in progress to determine whether the adenylate cyclase activity elicited by vanadate is GTP dependent.

The effect of vanadate on cyclic AMP formation in addition to its effect on (Na,K)ATPases may be of general interest, as vanadate exerts biological activities in several intact cellular systems. A positive inotropic effect of vanadate in electrically driven cat papillary muscles[10], and several pharmacological effects, among them a powerful peripheral vasoconstriction, have been reported[11].

Antibody against a stimulatory factor of RNA polymerase II inhibits nuclear RNA synthesis

THE mechanisms by which eukaryotic genes are differentially activated are mostly unknown. However, the most fundamental process of gene expression is thought to be transcription by RNA polymerase II, and thus the regulation of RNA synthesis by this enzyme is one of the important points of study of eukaryotic gene expression. It is generally believed that structural modification of chromatin governs the transcriptability of the template[1], and consequently studies have been carried out on the activity of chromatin[2–4]. Recently, another possibility has been considered, that various regulatory proteins may be involved in the process of transcription and regulate the gene expression[5]. However, although there are many reports of proteins stimulating the activity of RNA polymerase II *in vitro*[6–11], no conclusive evidence has yet been obtained to show that these proteins are, in fact, functioning in the process of nuclear RNA synthesis. We have purified a protein from Ehrlich ascites tumour cells that specifically stimulates the activity of RNA polymerase II on homologous DNA[12]. Named S-II, this is a basic protein with a molecular weight of 40,500. We report here that an antibody against S-II markedly inhibits RNA synthesis in isolated nuclei, but that it does not affect the activity of purified RNA polymerase II. These findings suggest that the processes of RNA synthesis in isolated nuclei and with purified RNA polymerase II and deproteinised DNA are basically different, and that S-II has an essential role in nuclear RNA synthesis.

Protein factor S-II was extensively purified from Ehrlich ascites tumour cells, and antibody against S-II was prepared by injecting S-II into albino rabbits. This antibody was found to inhibit the stimulatory activity of S-II specifically. Nuclei were prepared from Ehrlich ascites tumour cells by the method of Marzluff *et al.*[13], and were active in the incorporation of ^{3}H-UTP into RNA *in vitro*, in the presence of three other nucleoside triphosphates and salts.

First, we tested whether the antibody against S-II had any effect on RNA synthesis in the isolated nuclei. There are three species of RNA polymerase (I–III) in nuclei; RNA polymerases I and III, which synthesise ribosomal RNA and small molecular weight RNA, respectively, are fairly resistant to α-amanitin, whereas RNA polymerase II, which synthesises messenger RNA, is inhibited by α-amanitin[14]. Therefore, in tests on the effects of the antibody against S-II on the activities of these three enzymes, assays were carried out in the presence and absence of 5 μg ml^{-1} of α-amanitin. Nuclei were preincubated in the reaction mixture for RNA synthesis (see legend to Fig. 1) for 30 min at 0 °C with increasing amounts of antibody; the incubation temperature was then shifted to 25 °C and the incorporation of ^{3}H-UTP into the acid-insoluble fraction in 10 min was measured. The control contained immunoglobulin G prepared from non-immunised rabbit serum instead of antibody. As shown in Fig. 1*a*, the antibody inhibited nearly 50% of the α-amanitin-sensitive RNA synthesis, whereas normal IgG had little effect. Neither antibody nor normal IgG affected RNA synthesis in the presence of α-amanitin (Fig. 1*b*). These results clearly indicate that stimulatory factor S-II must be involved in some way in the RNA synthesis catalysed by RNA polymerase II in isolated nuclei, but that it is not related to α-amanitin-resistant RNA synthesis. The results are consistent with our previous findings with isolated enzymes that S-II specifically stimulated RNA polymerase II and did not stimulate RNA polymerase I at all.

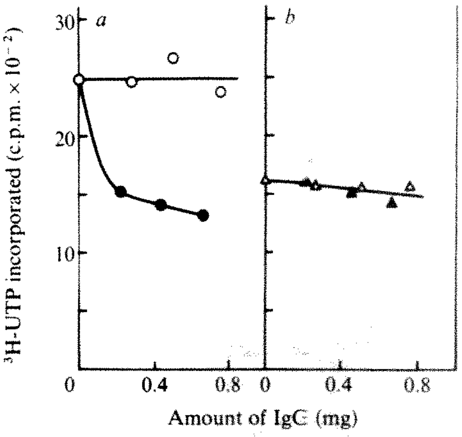

Fig. 1 Inhibition of nuclear RNA synthesis *in vitro* by antibody against S-II. The reaction mixture contained, in a total volume of 100 μl, 50 mM HEPES, *p*H 8.0, 0.25 mM each of ATP, GTP and CTP, 0.025 mM UTP, 2 μCi of ^{3}H-UTP (20 Ci mmol^{-1}), 1 mM $MnCl_2$, 5 mM $Mg(OAc)_2$, 150 mM KCl, 12 mM β-mercaptoethanol, 0.05% Triton X-100, 10% glycerol, 0.5 μg of α-amanitin when present, 2×10^5 nuclei and the indicated amount of antibody against S-II or normal IgG. The mixture was preincubated for 30 min at 0 °C, then at 25 °C for 10 min, after which acid-insoluble radioactivity was measured. *a*, Effect of the antibody on α-amanitin-sensitive RNA synthesis; *b*, effect of antibody on α-amanitin-resistant RNA synthesis. ●, ▲, Antibody; ○, △, normal IgG.

The question arises as to whether or not S-II is a component of the multimeric proteins of RNA polymerase II. We therefore tested the inhibitory effect of the antibody on purified RNA polymerase II. For this, we preincubated a fixed amount of purified RNA polymerase II with increasing amounts of the antibody at 0 °C for 30 min and then shifted the temperature to 37 °C and measured the incorporation of ^{3}H-UTP into RNA in 60 min. As a positive control, we measured the effect of the antibody on the stimulatory activity of S-II. As shown in Fig. 2, RNA polymerase II itself was not affected appreciably by either the antibody or normal IgG, whereas the stimulatory activity of S-II was specifically inhibited by the antibody but not by normal IgG. These results show that the antibody inhibits the activity of S-II. If S-II were an intrinsic component of multimeric proteins of RNA polymerase II, the antibody should have at least partly inhibited the activity of RNA polymerase II. It is possible that S-II is a component of native RNA polymerase II, but that it was split off during isolation of the enzyme because when multimeric proteins are extensively purified their subunits are sometimes lost during the purification step, as in the case of σ factor of *Escherichia coli* RNA polymerase[15]. However, in this study we used partially purified RNA polymerase II (ref. 16), which was more likely to retain an intact molecular structure than completely purified enzyme. Thus, the fact that the antibody did

0028–0836/79/0277—0145$01.00

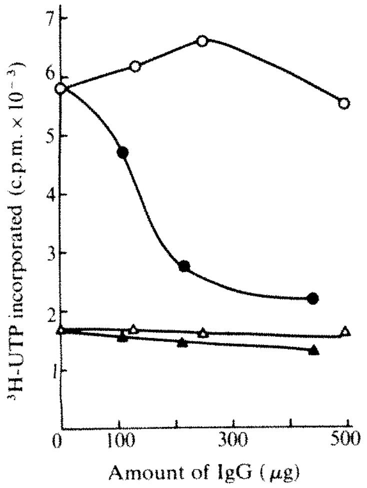

Fig. 2 Effect of the antibody against S-II on partially purified RNA polymerase II. The reaction mixture contained in a total volume of 250 μl, 40 mM Tris-HCl, pH 7.9, 3 mM $MnCl_2$, 4.6 mM $MgCl_2$, 50 mM $(NH_4)_2SO_4$, 0.068 mM EDTA, 4 mM β-mercaptoethanol, 0.25 mM each of ATP, GTP and CTP, 0.025 mM UTP, 0.5 μCi of ^{3}H-UTP (20 Ci $mmol^{-1}$), 5 μg of Ehrlich ascites tumour DNA, 20 units of RNA polymerase II (see ref. 16), 25 units of S-II when present (see ref. 12) and the indicated amount of antibody against S-II or normal IgG. The mixture was preincubated for 30 min at 0 °C, then at 37 °C for 60 min, and then acid-insoluble radioactivity was measured. ●, Antibody + S-II; ○, normal IgG + S-II; ▼, antibody, no S-II; △, normal IgG, no S-II.

not inhibit the partially purified RNA polymerase II strongly suggests that S-II is not an intrinsic component of RNA polymerase II.

From the results obtained here using specific antibody against stimulatory factor S-II, two important conclusions could be drawn about eukaryotic transcription. First, in the process of transcription α-amanitin-sensitive, nuclear RNA synthesis is not a simple process catalysed by RNA polymerase II, but in some way involves a regulatory protein(s) such as S-II. Second, the protein factors reported to stimulate RNA polymerase II *in vitro* are not necessarily components of the multimeric proteins of RNA polymerase II, but may exist as independent proteins that regulate transcription by interacting with the enzyme. Thus, in reconstruction of an accurate transcriptional system *in vitro* using purified RNA polymerase II and deproteinised DNA as template, attention must be paid to the effect of these stimulatory factors. This is the first report of evidence that a stimulatory factor is actually involved in nuclear RNA synthesis.

Phenotypic suppression and misreading in *Saccharomyces cerevisiae*

A NUMBER of antibiotics and other inhibitors have been useful in genetic and biochemical analyses of the protein-synthesising machinery of prokaryotic and eukaryotic organisms. Aminoglycoside antibiotics have been shown to be particularly helpful in this respect, especially in identifying ribosomal protein cistrons in bacteria. The aminoglycosides cause extensive misreading of the RNA code words *in vitro*[1] and suppress many nonsense and missense mutations in *E. coli*[2] phenotypically. The misreading observed in cell-free translation is believed to be the basis for the phenotypic suppression, although the exact mechanism is not known. Apart from a report of suppression of a single mutation in yeast by streptomycin[3], there have been no demonstrations of phenotypic suppression in eukaryotic organisms. Earlier studies of mistranslation *in vitro* in eukaryotic systems indicated that this phenomenon is rare. Streptomycin did not cause misreading with cytoplasmic ribosomes of rat liver[4], rabbit spleen[5], chicken liver[6] or yeast [7]; neomycin had no effect in rabbit reticulocyte extracts[4] and only a slight effect in the yeast and chicken liver systems[6,7]. These results suggested that translation in higher organisms functions with higher fidelity than that in bacteria. Nevertheless, aminoglycoside antibiotics have recently been shown to cause extensive translational misreading *in vitro* in systems derived from *Tetrahymena*[8], wheat embryo[9], and cultured human cells[10].

We report here that several aminoglycoside antibiotics (including hygromycin B, lividomycin, paromomycin and neomycin) cause phenotypic suppression of UAA (ochre), UAG (amber), and UGA mutations and also promote misreading *in vitro* in the simple eukaryotic organism *Saccharomyces cerevisiae*. Mutants resistant to hygromycin B have been isolated which exhibit altered levels of antibiotic-induced phenotypic suppression.

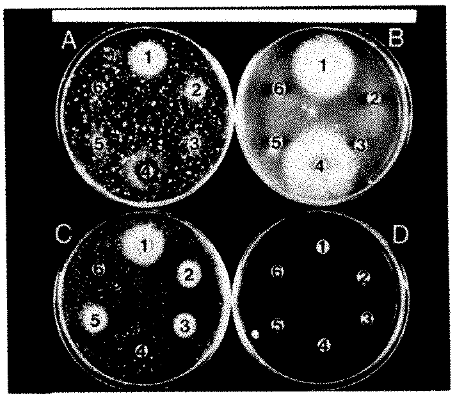

Fig. 1 Test for phenotypic suppression of an UAA (A) and an UAG (B) mutation by various aminoglycoside antibiotics. Strain A carrying an ochre (UAA) mutation, *trp5-48*, and strain B carrying an amber (UAG) mutation, *met8-1*, were grown in yeast extract–peptone–dextrose medium to stationary phase. Cells were collected by centrifugation, washed twice with sterile water and resuspended in water. Approximately 7.5 × 10^6 cells were spread on synthetic agar media. Sterile paper disks were placed as shown on which 500 μg (25 μl of 20 mg ml^{-1} aqueous solution) of the indicated antibiotics were dispensed. The antibiotics used were: 1, paromomycin; 2, lividomycin A; 3, gentamicin C_{1a}; 4, hygromycin B; 5, kanamycin B; and 6, kanamycin C. Petri dishes were incubated at 30 °C for 6 d and then photographed. The white growth surrounding a disk indicates phenotypic suppression. Strains C and D are mutants (see text) resistant to hygromycin B isolated from strains A and B, respectively. Tests with C and D were done exactly as described above for A and B.

Antibiotics were tested for phenotypic suppression of nonsense mutants of yeast as shown in Fig. 1; higher concentrations of antibiotics were also tested. Of 32 nonsense mutations tested, 18 were suppressible (Table 1) by one or more of the drugs. Only a few cases were found where a mutation not suppressed initially was suppressed when higher concentrations of antibiotic were used. The UAA mutation *trp5-48* and the UAG mutation *met8-1* were the most readily suppressible mutations of their respective classes. We therefore used these two mutations to test a variety of aminoglycoside antibiotics for their ability to cause phenotypic suppression (Table 2). Although paromomycin, hygromycin B and lividomycin B were generally the most efficient in causing phenotypic suppression, no clear-cut structure–activity relationship was evident. It has been reported[8-10] that only those aminoglycoside antibiotics that contain a 6′-hydroxyl group on the amino sugar linked to the 4-position of 2-deoxystreptamine were highly active in promoting mistranslation in eukaryotic cell-free systems. If suppression of auxotrophic mutations by the antibiotics in yeast is due to mistranslation, this structure–function relationship does not always apply. For example, in Fig. 1 (A, C) it can be seen that kanamycin B is substantially more active than kanamycin C; the reverse is predicted from *in vitro* mistranslation studies. In addition, several of the gentamicins were active.

Table 1 Nonsense mutations tested for phenotypic suppression

Mutation type	Suppressed*	Not suppressed
UAA	*trp5-48, lys1-1, leu2-1* *met15-30, met15-49,* *met15-85, met15-95,* *met15-119, met15-131*	*his5-2, ade2-1, arg4-17* *can1-100, met15-47,* *met15-70, met15-107*
UAG	*met8-1, ilv1-1, aro7-1* *ade3-26, met15-44* *met15-46, met15-72,* *met15-84*	*trp1-1, met15-21,* *met15-76*
UGA	*leu2-2*	*his4-166, his4-260*

* Suppressible by one or more antibiotics listed in Table 2.

Although most of the nonsense mutations were suppressed by one or more of the antibiotics, phenotypic suppression of missense mutants was rare. No auxotrophic mutations in yeast are known to be missense on the basis of amino acid substitution or nucleotide sequence data. A number of osmotic-remedial and/or temperature-sensitive mutants are, however, believed to be missense. Paromomycin, which is active on all phenotypically suppressible nonsense mutants (Table 1) was tested for suppression of isogenic series of missense mutants in the *met15* locus. Only one (*met15-33*) of 34 could be weakly suppressed. This mutant is osmotic-remedial, shows interallelic complementation and was not suppressible by amber and ochre suppressors[11]. The proportion of missense mutations that are suppressible in bacteria is lower than that of nonsense mutations[12], but it seems to be much higher than in yeast. The frequency of phenotypically suppressible mutants in a random sample of mutants was relatively low; we found only ten such mutants in a collection of 337 independent auxotrophic mutants isolated from a prototrophic strain.

Some of the ochre (UAA) mutants that we examined contain the cytoplasmic determinant ψ, which increases efficiencies of ochre[13,14] and some frameshift[15] suppressors but has no effect on amber suppressors[13]; ochre mutations were more readily suppressed by antibiotics in ψ^+ strains than in ψ^- strains. Since all the amber mutants were ψ^-, and the ψ state of UGA mutants was not determined, we do not know if the ψ^+ genetic determinant facilitates phenotypic suppression of UAG and UGA mutants.

Of the aminoglycosides listed in Table 2, only hygromycin B (ref. 16) and destomycin A (A. S., unpublished) inhibit the growth of *S. cerevisiae* on glucose nutrient medium. These are structurally similar, destomic acid-containing antibiotics. We have selected a large number of mutants resistant to hygromycin B; they are recessive and represent at least three complementation groups. The mutants exhibited a wide variation in the level of phenotypic suppression, ranging from the wild-type response to complete restriction. Two examples are shown in Fig. 1. The resistant mutant (C) isolated from the *trp5-48* strain (A) had a reduced level of suppression by hygromycin B. On the other hand, the hygromycin B-resistant mutant (D) isolated from *met8-1* strain was not detectibly suppressed by any of the antibiotics active on the parent strain (B).

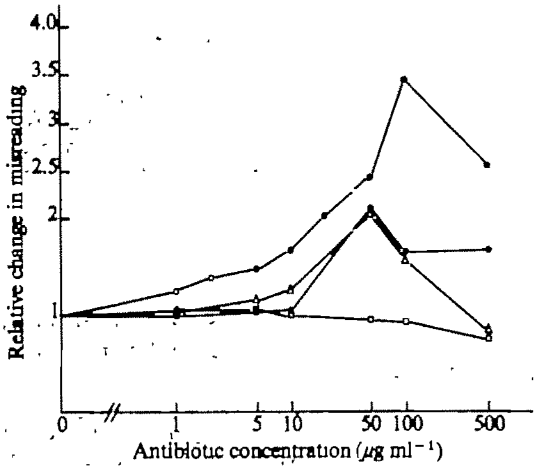

Fig. 2 Effect of aminoglycoside antibiotics on misreading in poly(U)-directed yeast cell-free protein synthesis. The 80S ribosomes and supernatant factors were prepared from wild-type yeast as described earlier[17]. The reaction mixture for poly(U)-directed incorporation of phenylalanine and leucine contained, in 50 μl: 50 mM Tris-hydrochloride, *p*H 7.7, 12.5 mM magnesium acetate, 80 mM KCl, 4 mM creatine phosphate, 40 μg creatine phosphokinase ml^{-1}, 250 μg yeast tRNA ml^{-1}, 1 mM dithiothreitol, 2 mM adenosine 5′-triphosphate, 0.1 mM guanosine 5′-triphosphate, 2 μM ^{14}C-phenylalanine (specific activity 486 mCi mmol^{-1}), 2 μM ^{3}H-leucine (specific activity 8.8 Ci mmol^{-1}), 300 μg poly(U) per ml, 1 mg ribosomes per ml, 2 mg supernatant enzymes per ml. Reactions were carried out at 30 °C for 45 min. 50 μl of 1 M NaOH was added and the mixture was incubated for an additional 20 min. After addition of one ml of 10% trichloroacetic acid the resulting precipitate was collected on glass-fibre filters (Whatman GF/C), washed with 5% trichloroacetic acid and dried. Radioactivity was determined in a toluene-based liquid scintillation solution. Absolute amounts of poly(U)-directed incorporation of phenylalanine and leucine were determined. The data are presented as ratios of misreading observed in the presence of the antibiotics to that found in their absence. As a typical value, the ratio of 1 corresponds to misreading (Leu/Phe ratio) of 4×10^{-3} which in turn corresponds to the incorporation of 50 pmol phenylalanine and 0.2 pmol leucine. ○, Hygromycin; B; ●, lividomycin B; △, paromomycin; □, streptomycin.

We have tested several aminoglycoside antibiotics for translational misreading, as detected by incorporation of leucine directed by poly(U) which does not contain leucine condons. As shown in Fig. 2, hygromycin B, paromomycin and lividomycin B, all of which caused phenotypic suppression, stimulated misreading 2- to 3.5-fold. The same drugs caused misreading when added to a natural mRNA-stimulated system (L. Gritz, unpublished observation). Streptomycin, which does not suppress any of the nonsense mutations, had no effect on eukaryotic translation. The mechanism of misreading by aminoglycoside antibiotics is not known; the interactions between these drugs and pro- and eukaryotic ribosomes are presumably different, since different structure–function relationships are involved. The analysis of the ribosomes of resistant mutants should be

Table 2 Aminoglycoside antibiotics tested for phenotypic suppression activity

Antibiotic class	Active	Not active
The 4,5-disubstituted deoxystreptamine antibiotics	Neomycins B and C, lividomycins A and B, paromomycin	Butirosins A and B
The 4,6-disubstituted deoxystreptamine antibiotics	Kanamycins A and B, tobramycin, gentamicins X_2, C_{1a}, C_2, A_1; sisomicin	Kanamycin C, gentamicins A, B C_1, A_2
The monosubstituted deoxystreptamine antibiotics	Destomycin A, hygromycin B	
Others		Fortimicin A, kasugamycin, streptomycin

profitable in this respect. Hygromycin B has been shown to be an inhibitor of translocation in eukaryotic translation[18] and slowing of this process by the drug may increase the rate of incorporation of incorrect amino acids.

Our studies provide a basis for the genetic and biochemical analysis of mutants which may affect fidelity of translation in yeast and it should be possible to isolate and analyse mutants of the ribosomal ambiguity type in *S. cerevisiae* that have been exploited by Gorini and his coworkers in *E. coli*. In addition, antibiotic-induced phenotypic suppression may provide a convenient and quick screening method for nonsense mutants in eukaryotes. Paromomycin is a potent agent for phenotypic suppression and causes mistranslation *in vitro*, but has no measurable affect on *S. cerevisiae* growth. If the two processes are related, this eukaryote must be capable of tolerating extensive translational errors without apparent harm. This raises an interesting point with respect to the error catastrophe theory of translation errors in ageing.

We thank Edward Palmer, J. Wilhelm and F. Sherman for their willingness to exchange information on this subject and Drs G. Fink and M. Culbertson for the UGA mutants. This work was supported by NIH grant AI12448 and Viral Oncology Training Grant T32-CA-09075.

Phenotypic suppression of nonsense mutants in yeast by aminoglycoside antibiotics

STREPTOMYCIN, an aminoglycoside antibiotic, can reverse the mutant phenotypes of many nonsense and missense mutations in *Escherichia coli* and in bacteriophage T4. This phenomenon has been called phenotypic suppression, since the mutant phenotype returns after removal of the drug[1]. The most likely explanation for phenotypic suppression is that streptomycin promotes mistranslation *in vivo*, and that acceptable amino acids are inserted into the growing polypeptide chain at the site of the mutant codon. Consistent with this view is the observation that streptomycin causes *E. coli* ribosomes to mistranslate RNA *in vitro*[2,3]. Streptomycin and neomycin have however been found to have no effect in stimulating ribosomes from eukaryotic cells to mistranslate RNA *in vitro*[4,5]. A subclass of the aminoglycoside antibiotics has been shown[6,7] to stimulate eukaryotic ribosomes to misread RNA. The highly active molecules are distinguished in that they contain the drug fragment paromamine (or 3′-deoxyparomamine). We have therefore examined the capacity of various aminoglycosides to suppress mutations phenotypically in the eukaryotic yeast, *Saccharomyces cerevisiae*. The results presented here show that paromomycin, which contains paromamine, is capable of phenotypic suppression of the nonsense mutations in *S. cerevisiae*.

The data of Fig. 1 show the relative ability of various antibiotics to suppress the methionine requirement of a yeast strain carrying the amber mutation *met8-1*. It is clear that in the presence of streptomycin, distilled water or cycloheximide, only rare isolated revertants appear, whereas paromomycin, one of the paromamine-containing drugs, supports a dense mat of growth around a paper disk containing this antibiotic. Although it is not obvious in the figure, neomycin causes a limited ring of growth around the disk.

Singly-cloned cells from the plate containing paromomycin were isolated and tested for their methionine requirement. All of the tested clones were still auxotrophic for methionine, indicating that paromomycin had not induced any permanent revertants. Additional nonsense mutants were tested for their ability to be phenotypically suppressed. The results (Table 1) indicate that 14 of the 17 mutants tested can be phenotypically suppressed with paromomycin, whereas only six mutations are suppressed with neomycin, albeit weakly. The mutations suppressed by paromomycin represent lesions in eight different metabolic pathways and in 11 different structural genes. It is therefore highly unlikely that paromomycin is directly supplying the growth requirements for all of the mutants. Paromomycin

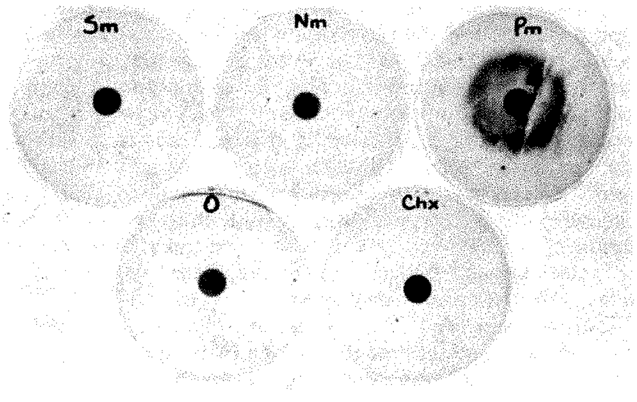

Fig. 1 Approximately 10^7 cells were plated on synthetic media[13] containing no methionine. A paper disk, saturated with 7 μmol (5 mg except cycloheximide 2 mg) of antibiotic, was placed in the centre of each plate and the plates were incubated at 30 °C for 3 d. Sm, Streptomycin; Nm, neomycin; Pm, paromomycin; Chx, cycloheximide; O, distilled H_2O.

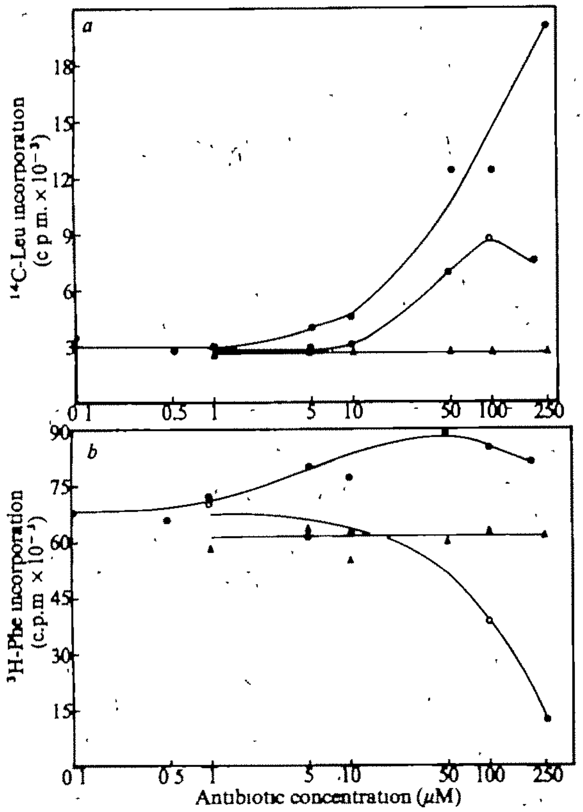

Fig. 2 Yeast cells (strain HL100-1C) were grown in standard nutrient medium (1% yeast extract, 2% peptone, 2% dextrose) to 8×10^7 cells ml^{-1}, collected and washed twice with distilled H_2O. The cells were resuspended in homogenising buffer (20 mM HEPES, 4 mM Mg acetate and 100 mM KCl, pH 7.6) and disrupted with glass beads in a Braun mechanical cell homogeniser. The preparation of the extract and the conditions for cell-free protein synthesis are described elsewhere[6]. The final concentrations of Mg acetate and KCl in these yeast cell-free systems were 15 mM and 100 mM respectively. *a*, Poly(U)-dependent misincorporation of leucine; paromomycin (●), neomycin (○); streptomycin (▲). *b*, Poly(U)-dependent incorporation of phenylalanine, paromomycin (●), neomycin (○), streptomycin (▲).

can also suppress all three types of nonsense codons, UAG, UAA and UGA (Table 1). The strongest growth response to paromomycin was given by the markers *met8-1* and *trp5-48*, neither of which mutation could be suppressed by streptomycin (Fig. 1 and data not shown).

Growth in liquid cultures indicates that paromomycin can exert suppression at concentrations as low as 50 μM (35 μg ml^{-1}). The concentration of paromomycin for optimal suppression of most mutations is approximately 100 μM.

Cell-free translation systems were prepared from yeast and the ability of paromomycin, neomycin and streptomycin to cause *in vitro* misreading was measured by the misincorporation of leucine with a poly(U) template (UUpyr codes for phenylalanine, whereas CUN and UUpur code for leucine). The data in Fig. 2*a* show that paromomycin is active in stimulating leucine errors, yet streptomycin has no activity. Neomycin can stimulate leucine errors, although its activity is substantially weaker than that of paromomycin, especially at low concentrations. The data of Fig. 2*b* show that concentrations of neomycin which stimulate misreading also inhibit protein synthesis, whereas paromomycin stimulates mistranslation without inhibiting cell-free protein synthesis. This inhibition may account for the very limited phenotypic suppression seen with neomycin, even though the drug has some misreading capacity *in vitro*.

Phenotypic suppression can occur by several distinct mechanisms. The phenotypic reversal of mutant characters in yeast by hypertonic media is interpreted as an elevation of the osmotic pressure optima of certain mutationally altered proteins[8]. 5-Fluorouracil and related analogues are believed to reverse mutant phenotypes in bacteria[9,10] and in *Neurospora crassa*[11] temporarily, by incorporation into mRNA, resulting in the pairing of 5-fluorouracil containing codons with incorrect tRNAs.

Nonsense mutations in *S. cerevisiae* which can be suppressed with paromomycin or neomycin. Cells were plated on the appropriate omission media for the indicated markers and incubated for 7 d with antibiotic containing disks as described for Fig. 1.

* Phenotypic suppression of the indicated marker only seen in cells containing the extrachromosomal element ψ^+ (in preparation).

† Not determined.

Since the paromamine-containing aminoglycosides bind to the cytoplasmic ribosomes of *Tetrahymena* and wheat embryos (unpublished observations), and since these drugs presumably bind to the cytoplasmic ribosomes of yeast, the suppression of many nonsense mutants by paromomycin reported here suggests that phenotypic suppression in eukaryotes can occur with agents which affect directly the functioning of the ribosome. It should be noted that Bayliss and Vinopal[12] reported the suppression of an *his1* missense mutant with streptomycin; however, extremely high concentrations of streptomycin were required to exert this suppression. It seems as if phenotypic suppression requires a 300-fold higher concentration of streptomycin, relative to paromomycin.

The paromamine-containing drugs should thus be useful in the isolation and characterisation of ribosomal mutants of eukaryotic cells which are altered in their translational fidelity. In addition, these agents should be helpful in the isolation of nonsense mutants and nonsense suppressors in eukaryotic organisms other than yeast. Most importantly, however, the paromamine-containing aminoglycosides should make possible a close examination of the consequences of protein synthesis errors in eukaryotic organisms.

X-ray absorption edge fine structure spectroscopy of the active site haem of cytochrome *c*

THE new technique of extended X-ray absorption fine structure spectroscopy (EXAFS)[1] offers promise of detecting small changes in conformation around a central metal atom at the active site of a metalloenzyme, and of relating such changes to the catalytic mechanism. An advantage of EXAFS studies over X-ray diffraction is that they can be carried out in solution at physiological pH where the protein can freely interact with its substrate. We describe here EXAFS measurements aimed at detecting conformational changes during reduction of horse heart cytochrome *c*.

Figure 1*a* shows the EXAFS-spectrum of reduced cytochrome *c* at pH 7, 20 °C, plotted against wave vector $\mathbf{k} = [0.263\,(E - E_0)]^{1/2}$. E and E_0 are the X-ray photon and iron K-edge energies in eV respectively. X-ray photons with energies comparable to or larger than the Fe-1s-electron binding energy (E_0) are absorbed by the iron thereby promoting the 1s electron to empty bound states (K-edge region) or into the continuum (EXAFS region). Two kinds of information can be deduced from an X-ray absorption spectrum. First, from the K-edge region information regarding the electronic state of the iron in the porphyrine frame and second, from the oscillatory region (EXAFS region) the mean bond lengths between the iron and its nearest neighbours (relative to a model compound used as standard). The technique has been reviewed in detail elsewhere[1].

Table 1 $R_1' = R_1 - a/2$ for the first coordination shell [four pyrrole nitrogens, one nitrogen from His 18 and one sulphur from Met 80 (at low pH) or one nitrogen from Lys 79 (at high pH)]

Reduced cytochrome *c*, pH 7*†	1.47 ± 0.03 Å
Oxidised cytochrome *c*, pH 7*	1.47 ± 0.03 Å
Oxidised cytochrome *c*, pH 10	1.40 ± 0.03 Å

Values as obtained from maximum energy transforms[7]. The individuals atoms of the first coordination shell cannot be resolved.

* In 0.1 M sodium phosphate buffer.

† Reduction was achieved by adding an equimolar amount of L ascorbate.

‡ In 0.1 M glycine buffer.

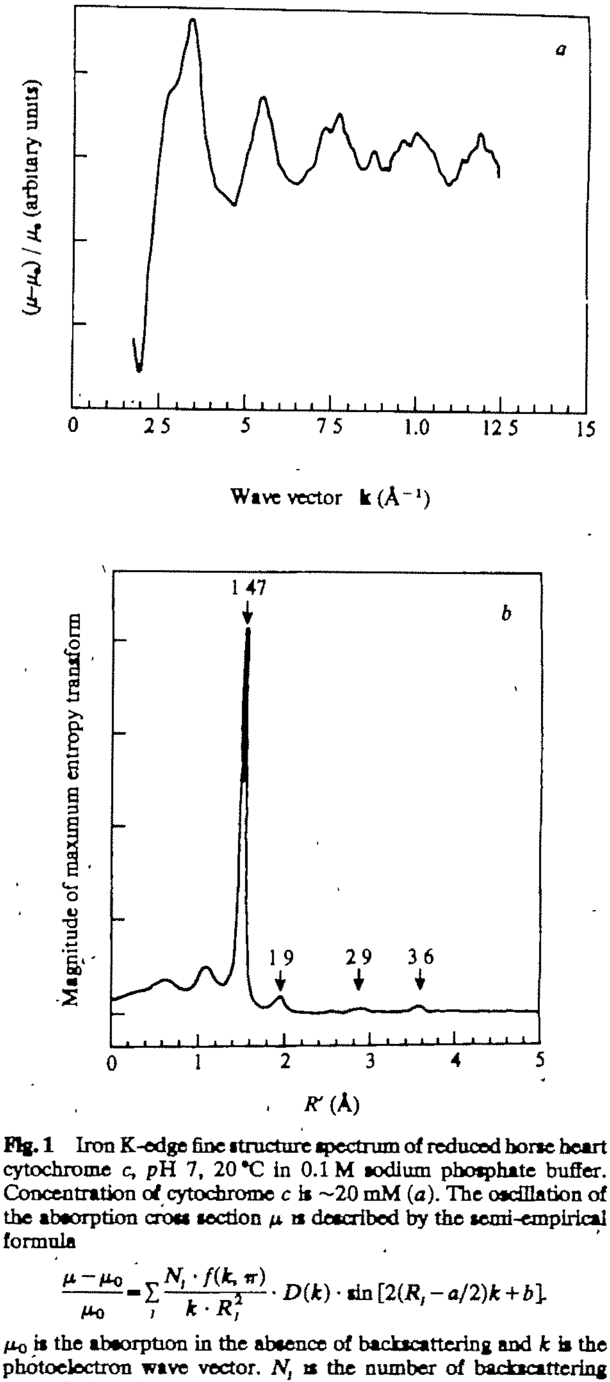

Fig. 1 Iron K-edge fine structure spectrum of reduced horse heart cytochrome *c*, pH 7, 20 °C in 0.1 M sodium phosphate buffer. Concentration of cytochrome *c* is ~20 mM (*a*). The oscillation of the absorption cross section μ is described by the semi-empirical formula

$$\frac{\mu - \mu_0}{\mu_0} = \sum_i \frac{N_i \cdot f(k, \pi)}{k \cdot R_i^2} \cdot D(k) \cdot \sin\,[2(R_i - a/2)k + b].$$

μ_0 is the absorption in the absence of backscattering and k is the photoelectron wave vector. N_i is the number of backscattering atoms in the spherical shell of radius R_i surrounding the absorbing iron. $f(k, \pi)$ and $D(k)$ are the back-scattered amplitude and the Debye–Waller factor respectively. The maximum entropy transform[7] of the spectrum will as a function of the transformation parameter R' show peaks at $R_i' = R_i - a/2$ (*b*). The phase shift $a/2$ is given by the electronic inner shell properties of the absorbing and backscattering atoms and was therefore assumed to be the same for all samples measured. Changes in R_i' are then equal to a corresponding decrease or increase in R_i. The two small peaks in the transform at $R' = 0.6$ Å and 1 Å are spurious and come from an improper background removal (μ_0).

In native conditions (pH 7, 20 °C) the iron of cytochrome *c* is sixfold coordinated. Positions five and six are occupied by the ε-nitrogen of His 18 and the sulphur of Met 80 (ref. 2). In this state it can be reversibly reduced and oxidised. The molecular details of this process are not fully understood. From antibody Fab fragment binding studies[3] it is known that human cytochrome has two different binding sites for the cytochrome *c* oxidase and the succinate cytochrome *c* reductase. The question has been raised as to whether there is a conformational change on reduction[2] which modulates the binding affinity of the two sites to their respective substrates. The latest X-ray diffraction results[4] on cytochrome *c* have a resolution of 2 Å and report the structures of ferric and ferrous cytochrome *c* from tuna which at this resolution do not differ significantly apart from the conformations of a few surface side chains. The early ferric horse heart map[2] showing considerable orientation changes in aromatic side chains and a slight main chain rearrangement to the first ferrous tuna map[5] is now believed to be incorrect.

0028-0836/79/0277—0150$01 00

The local resolution that can be obtained in EXAFS measurements is considerably higher than by X-ray diffraction. Any conformational change, occurring on reduction is expected to be triggered by the haem. Table I shows the uncorrected values R'_1 (see legend to Fig. 1 for the definition R' of R'_1) for the distance of the first coordination shell from the iron. These values were obtained by calculating the maximum entropy transform[6,7] of the EXAFS spectra as described previously[8]. The magnitude of the transform is plotted as a function of the transformation parameter R' in Fig. 1*b*. We estimate from their reproducibility that the R'_1 values are accurate to ±0.03 Å. Within these limits we cannot see a conformational change in the haem region on reduction. On the other hand, H-exchange experiments[9] on horse heart cytochrome *c* show that the number of slowly exchanging amide protons is significantly higher for the reduced protein. This is interpreted by the authors[9] as unambiguous indication of a conformational rearrangement. In view of the current high resolution EXAFS results we would rather suggest a change in the amplitudes of some low frequency vibrations. The oxido-reduction then shifts the equilibrium between two conformers

$$R^{2+} \leftrightarrow F^{3+}$$

(R standing for rigid and F for flexible) with almost the same time averaged coordinates. Such a 'conformational' transition can be brought about by a variation in bond density (rather than bond length) between the iron and its ligands. It is known that the haem plays an important part in stabilising the folding and that apo-cytochrome *c* does not fold at all[10]. Also the binding of *N*-acetyl-DL-methionine to the haem octapeptide (residues 1–8) has a smaller dissociation constant for reduced octapeptide[11]. Similarly in ferric cytochrome *c* the sulphur atom of Met 80 ligating the haem at neutral *p*H is replaced at high *p*H by a nitrogen (most likely from Lys 79)[12]. This exchange does not occur for ferrous cytochrome *c*. Table 1 gives the value of R' for this high *p*H ferric form of cytochrome *c*. The apparent shortening of the first coordination shell distance by 0.07 Å is marginal in view of the estimated uncertainty of ±0.03 Å for R'. Whether the change in vibrational state or flexibility can alter physical properties such as the specific binding affinity has to await further elucidation.

Fig. 2 Iron K-edges and K-edge derivatives of reduced and oxidised cytochrome *c* and *p*H 7, 20 °C in 0.1 M sodium phosphate. Cytochrome *c* concentration is 20 mM.

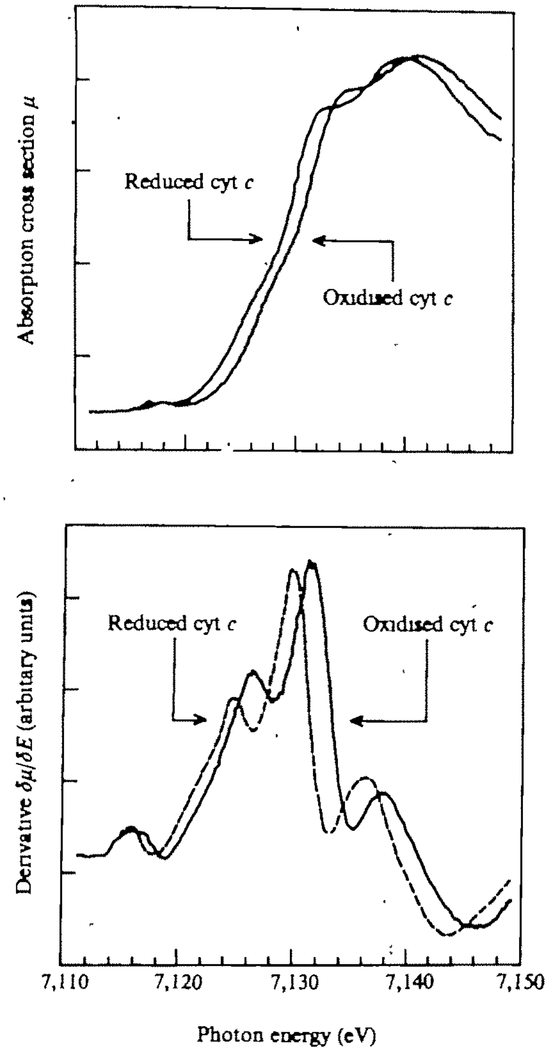

Table 2 Cytochrome *c* K-edge inflection point energies relative to the third inflection point of the K-edge of an iron foil (defined as 7130 eV)

	Oxidised cytochrome *c*		Reduced cytochrome *c*	
	1s–4s	1s–4p	1s–4s	1s–4p
*p*H 1.5	−2.4 eV	+1.5 eV	Unstable	
*p*H 7.0	−3.4 eV	+1.6 eV	−4.8 eV	+0.2 eV
*p*H 10.5	−3.1 eV	+1.7 eV	−4.6 eV	+0.4 eV

Buffers: 0.1 M glycine (low and high *p*H) and 0.1 M sodium phosphate. Cytochrome *c* concentrations range from 20 mM to 35 mM. No effect of the concentration on the K-edge positions could be detected.

Figure 2*a* shows the Fe-K-edge spectra of reduced and oxidised cytochrome *c* at *p*H 7. The edge structure is enhanced by differentiation with respect to photon energy (Fig. 2*b*). Three distinct transitions at photon energies smaller than the 1s electron ionisation energy can be seen. These transitions to empty bound states have been tentatively assigned to the 1s–3d, 1s–4s and 1s–4p transitions[13]. As seen from Fig. 2*b* there is a shift of the 1s–4s and 2s–4p transition by +2 eV on oxidation. This result is highly reproducible and in its most simple interpretation argues against extensive delocalisation of the electron added during reduction. It is in contradiction to results published earlier[13], in which no change in electronic state was detected on oxidation. Moreover, we find practically no effect on the K-edge position when raising the *p*H, resulting in the exchange of the Met 80 sulphur by nitrogen. Table 2 gives the complete set of energies for the 1s–4s and 1s–4p transitions relative to the K-edge energy of an iron foil (7130 eV).

Note that we could not detect any degradation of cytochrome *c* after exposure to the high X-ray flux when checked by the optical absorption spectrum or the kinetics of ascorbate reduction[14].

matters arising

Was Venus born retrograde?

INGERSOLL AND DOBROVOLSKIS[1] have disputed my theory[2] of the atmosphere of Venus. The key quantity in both analyses is the accelerating atmospheric torque T_A, evaluated in equations (2) and (22) of refs 1 and 2 respectively. The latter expression is determined from observations to within some 30%, while the former contains the unknown 'thermal response time' τ for mass transport in the atmosphere, for which the authors suggest values between some weeks and infinity. But sound waves can travel around the planet within some 10^5 s, hence I expect τ to be about a day; and for this value, both determinations of T_A give the same answer.

The other important quantity is the braking solid body tidal torque T_B which depends on the average value of the quality factor Q divided by the tidal Love number k_2. Estimates for $Q/4k_2$ range from 30 to $\gtrsim 10^5$ (refs 3, 2). In view of the different spin rate, chemistry and thermal history of Venus, a comparison with Earth need certainly not be trusted. An equality $T_A \approx T_B$ can therefore at best be conjectured. In ref. 1, this equality is suggested to hold within less than 2%, an unlikely event without independent justification.

For this and the other reasons put forward in ref. 2, I still believe in the law of isochronism: that all Solar System secondaries were born with a prograde spin period between 5 and 10 h.

INGERSOLL AND DOBROVOLSKIS REPLY—The questions which have been raised concerning the tidal torque on the atmosphere of Venus[1] deserve some clarification.

The atmospheric torque evaluated in equation (22) of ref. 2 depends on the coefficient of viscosity in the upper atmosphere of Venus. Because this is undoubtedly dominated by eddy momentum transport instead of molecular diffusion, the coupling between the upper and lower atmosphere is uncertain by orders of magnitude, not by 30% as claimed by Kundt.

The thermal response time τ is introduced in ref. 1 to parameterise unmodelled effects which tend to damp the atmospheric tides. It is not necessarily related to mass transport, and has nothing to do with the speed of sound waves (an entirely separate phenomenon). The main conclusions of ref. 1 (see our Fig. 2) are based on the undamped case $\tau \to \infty$.

Regarding the solid body torque, a value for Q of the order of 30 is not only suggested by analogy with the Earth, Moon and Mars, but is required (on the average) if Venus has despun from an originally rapid rotation, whether prograde or retrograde. Nevertheless, it is true that the near-equality (in the opposite sense) of the atmospheric and body tidal torque ($T_A \approx T_B$) is a conjecture. This hypothesis was originally advanced by Gold and Soter[3] to explain the nonsynchronous rotation period of Venus.

These and similar questions are dealt with in greater depth in a forthcoming series of paper, as well as in ref. 4.

An alternative hypothesis for the origin of West African kimberlites

MARSH[1] suggested in 1973, that the alkaline intrusives along the coast of southwestern Africa occurred where oceanic fracture zones extended under the adjacent continents. Recently Williams and Williams[2] have used this suggestion to attempt to explain the origin of the West African kimberlites. Their interpretation rests heavily on the accuracy of kimberlite and transform fault locations in their Fig. 1, on the assumption of Mesozoic ages for all of their kimberlites, and ignores the important occurrences in the same region of pre-Mesozoic kimberlites and alluvial diamond deposits.

Williams and Williams' hypothesis assumes West African diamond deposits to be Mesozoic, whereas the deposits in Ghana, Upper Volta, the Ivory Coast and Mali are Proterozoic or Infracambrian[3–8]. Their reference to kimberlites in Ghana is incorrect. Their location of a 'kimberlite' in Ghana fits the location of a few diamonds in a stream panning exercise[3] while the largest diamond fields of West Africa (placer), located in southern Ghana, are omitted. Their 'kimberlite' in Nigeria is a lamprophyre dyke located between Zaria and Sokoto (P. J. T. Verheijen, personal communication). Likewise, their postulated inland continuations of transform fault zones contradict without explanation the generally accepted trends[9] of these zones: the Chain and Charcot into the Benue trough,[9] the Romanche into the Keta basin bearing toward Ibadan,[9,10] and the St Paul entering the Ivory Coast east of Sassandra bearing ENE[9,10]. Thus the ages and locations of kimberlites as well as the positions of transform faults and their postulated landward continuations used by Williams and Williams[2] disagree with those established in the literature, with no explanation for this disagreement.

The geographical pattern of kimberlite pipes and the larger diamond placers can be more accurately interpreted (Fig. 1) as occurring along a primary arc running from Ghana through the Ivory Coast and Liberia to Sierra Leone[11]. In such a case the occurrence of young kimberlites is brought into coincidence with all of the much older kimberlites and alluvial deposits in the same general region. In addition there is a possibility of a second, roughly parallel arc extending from northern Ghana through Upper Volta, the Ivory Coast, Mali and Senegal. Known ages of major deposits along the primary arc include the diamonds contained in and above Birimian meta-sediments (2,200 Myr) in Ghana[3,4], the Seguela and Kanangono kimberlites (1,429 Myr) in the Ivory Coast[5,7], and the Sefadu and Koidu kimberlites (140–92 Myr) in Sierra Leone[6]. Along the second arc, the Kenieba kimberlites of Mali have been dated at 1,072 Myr (ref. 5). The geology of these deposits and the age determination techniques and results are discussed elsewhere[3–8]. Such a long history of progressive east to west arcuate diamond-bearing belts requires more than an association between Mesozoic kimberlites and post-Palaeozoic ocean fractures.

An equally viable explanation might be the existence of a long-lived mantle

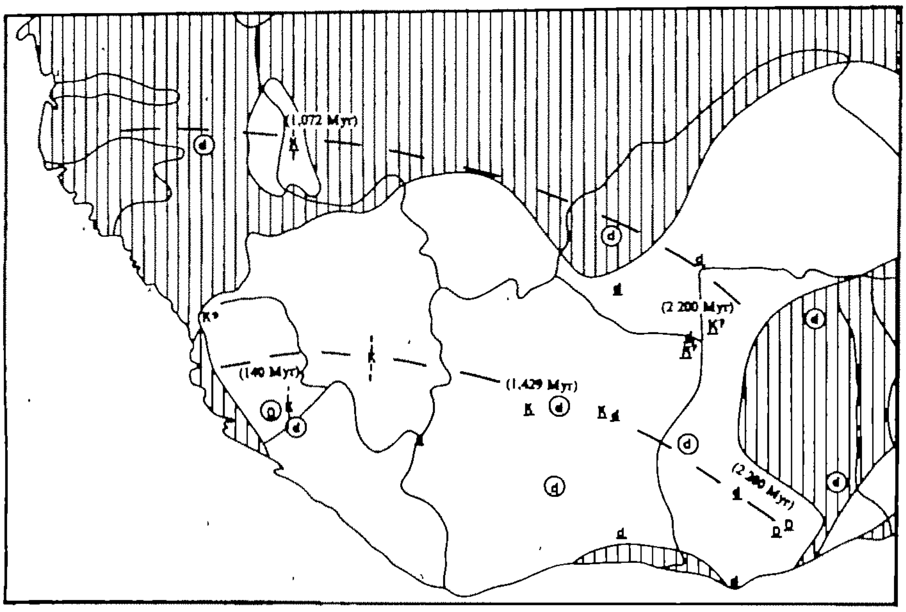

Fig. 1 Diamond and kimberlite occurrences in West Africa. K designates kimberlites (kimberlite belts are denoted with vertical caps and bases), D denotes major secondary diamond deposits, d marks minor secondary diamond occurrences. Underlined symbols are Precambrian in age, other deposits are younger. Circled symbols are alluvial deposits without age determinations; vertically shaded areas are covered with platform or basin sediments. Dates are given for diamond districts in which determinations have been made.

plume[12] producing a kimberlitic magma[13–15]. Then the alluvial deposits and kimberlites of the primary arc could be explained by the slow migration of such a plume from Ghana across the Ivory Coast to Sierra Leone with a long-term relative rate of motion of 0.8 mm yr^{-1}. The deposits on the secondary arc could be explained and would be consistent with a second but possibly weaker plume located north-west from the first plume, roughly in line with the Atlantic continental marginal intersections of the two arcs.

Such a hypothesis is consistent with the longevity, movement, and episodic nature of other hot spots such as the Hawaiian Chain[16]. The intrusion through the continents may be more episodic in nature, being shut off during periods of continental compression and opening up during periods of continental tension. Following the splitting of Africa from South America the rate of relative movement of the plume should have increased greatly. This would place the present position of the hypothetical plume, by extrapolation of the primary arc, at St Paul's Rocks on the Mid-Atlantic Ridge. This is known to be an active hot spot[17] and includes rocks with close affinities to kimberlites and carbonatites[18] as well as uplifted mantle material[19].

H. R. AND R. A. WILLIAMS REPLY—Hastings and Sharp[1] have attempted to explain the distribution of Precambrian to Mesozoic kimberlites in West Africa by means of two long-lived mantle plumes, the major one tracking from Ivory Coast to Sierra Leone with time. Their criticism of our hypothesis[2] that kimberlites occur along fundamental crustal fractures affected by oceanic lineaments, is unacceptable, especially as our hypothesis has been confirmed by Stracke[3] in south-east Australia, following his visit to Sierra Leone.

Hastings and Sharp have criticised our choice of data, particularly the ages of kimberlites, their location, and that of transform fracture zones. With regard to the first, the reliability of much radiometric dating of kimberlites and other lithologies is fraught with problems[4–7] as shown by kimberlites in Mali, Liberia and Ivory Coast. Argument over the locations of kimberlites and fracture zones probably stems from the small-scale of our Fig. 1. However, some loci of our hypothetical continental continuations of transform fracture zones are ill-defined, but this is due to the scarcity of readily accessible, reliable Geological Survey data in West Africa. We did not include the diamond fields of southern Ghana in our Fig. 1 because we were discussing only the distribution of Mesozoic kimberlites. We are fascinated by the Nigerian kimberlite which has allegedly become a lamprophyre, but this does not subdue our hypothesis, as Scott[8] relates lamprophyres to kimberlites by a simple crystal fractionation process.

With regard to movement of mantle plumes over a period of nearly two billion years, we suspect that an arcuate locus is facile. The movement of the African plate since the Palaeozoic has been roughly northwards, as shown by the building of the Alps, the age succession of the Nigerian Younger Granites, and by palaeomagnetism. If Hastings and Sharp seriously consider that since the mid-Proterozoic plate movement relative to an assumed hot spot may be described as an arc, then we refer them to refs 9 and 10 for illumination.

The problem of thrown string

BASS AND BRACKEN[1] have proposed a probabilistic model to explain existing experimental results on the average length between the ends of a string when thrown onto a table. The theoretical values obtained from their model are not consistent with the available experimental evidence. However, the model presented seems to be a plausible description of the physical situation. We suggest here a

0028-0836/79/0277—0153$01 00

modification which takes into account the effect of the desire of the experimenter to obtain a random set of throws. We argue that the experimenter tries in his throws to obtain initial distances between the ends of the string (by initial we mean the distance just before the string begins to fall) which follow a uniform distribution. We contend that in this case the distribution of distances between the ends of the string just before it hits the ground is a mixture of equal proportions of a uniform distribution and the distribution proposed by Bass and Bracken[1]. If this argument is true the density function for λ, the ratio of the distance between the ends of the string at the end of each experiment to its total length, is

$$\omega(\lambda) = \tfrac{3}{4}[\tfrac{5}{3}\arccos\lambda - \lambda(1-\lambda^2)^{\frac{1}{2}}]$$

This gives $E(\lambda) \simeq 0.343$ and $E(\lambda^2) \simeq 0.178$ in striking agreement with the data. Bass and Bracken suggested that a proportion of the throws were conducted close to the table surface and if this were so, their model would give a better agreement with the data. It is easy to show that 38.5% of the throws are required to be near the table surface in order to give a good agreement with the experimental results.

We feel that our assumption is more realistic. However, the controversy on this problem will only be resolved when new experimental results are obtained and all the details of the experiment become available.

BASS AND BRACKEN REPLY—Synge[1] has noted and rejected in passing the unfounded hypothesis that all possible end-to-end distances D of the string of length L lying on the table are equally probable (leading to $\bar{D}/L = \frac{1}{2}$). A modified version of that hypothesis would be that all possible end-to-end distances of the string in space (before impact with the table) are also equally probable. Taking into account the projections of the string on to the plane table[2], the probability density function for the ratio $\lambda = \bar{D}/L$ is then $\arccos\lambda$ (leading to $\bar{D}/L = \pi/8 \simeq 0.39$). The implausibility of the hypothesis leading to this distribution is apparent from the consideration that the number of configurations of the string consistent with an end-to-end distance x is much greater when x is near 0 then when x is near L.

If a fraction, p, of the throws conformed to our model[2], and $1-p$ to the hypothesis of equiprobability of end-to-end distances (in space), the resulting probability density of λ would be the combination

$$\frac{3p}{2}[\arccos\lambda - \lambda(1-\lambda^2)^{\frac{1}{2}}] + (1-p)\arccos\lambda\,;$$

and if p could be treated as an adjustable parameter, agreement with observations could obviously be improved[3]. We have not been able to find any rational basis for such a combination with $p \neq 1$. In particular, we cannot see that the choice $p = \frac{1}{2}$ would arise from the circumstance that "the experimenter tries in his throws to obtain initial distances between the ends of the string . . . which follow a uniform distribution"[3].

Is lymphocytic chalone activity restricted to a spermine–protein complex?

THE nature of lymphocytic chalones which are supposed to be tissue-specific but not species-specific inhibitors of cell proliferation, as defined by Bullough[1], remains a matter of controversy. They were characterised as 50–30,000-dalton factors[2,3] but detected also in the lower molecular weight range[4,5]. Recently Allen *et al.*[6] have proposed spermine as one candidate for an *in vitro* chalone activity. Spermine, present in a porcine thymus extracts as a protein complex, inhibited *in vitro* lymphocyte mitogenic response only when fetal calf serum (FCS) was added to the culture medium. FCS seems to act through polyamine oxidation, and its requirement for the inhibitory activity of spermine as well as spermidine was confirmed by Byrd *et al.*[7]. On the other hand, Rijke and Ballieux[8] have found a chalone-like non-dialysable factor in calf thymus extract differing from spermine complex in that its *in vitro* activity was FCS independent.

We have studied a non-dialysable fraction extracted from bovine spleen characterised previously as a lymphocytic chalone[3]. We demonstrated that most of the activity could be dissociated from high molecular weight carriers and recovered in a low molecular weight fraction[5,9] exhibiting chalone activity[10]. After chromatography, this fraction gave a purified spleen extract (PSE) whose effect was then compared with those of spermine and spermidine in mice. PSE (2×25 μg) was injected intraperitoneally. Twenty-four hours later, spleen, testis, kidney and liver cells were incubated with ^{3}H-thymidine. The radioactivity incorporated into DNA of cells was significantly reduced for spleen (39%, $P < 0.005$) but not in liver, testis and kidney cells. PSE treatment depressed both the number of plaque-forming cells of sheep red blood cell-sensitised mice to 80% ($P < 0.001$), as well as cellular immunity to dinitrofluorobenzene up to 51% ($P < 0.01$), as measured by ear thickness in sensitised mice. Conversely, as judged from the same tests, no significant difference was observed between polyamine-treated mice. These results demonstrate that various factors different from spermine exhibit chalone activity.

ALLEN REPLIES—I believe that inhibitors of lymphocyte mitosis are not restricted to spermine–protein complexes. In our article[1] we described how the activity of lymphocyte chalone preparations of the type originally used by Garcia-Giralt *et al.*[2] and Lenfant *et al.*[3] could be almost entirely attributed to the presence of spermine. We felt that 'these results emphasise the difficulties associated with the isolation of a lymphocyte chalone, but by no means rule out its existence'[1]. Several groups, having heeded our warning and having now eliminated polyamines from their extracts, are finding that inhibitory activity persists. Dr Lenfant's material is interesting in that it seems to be inhibitory both to the proliferation and function of lymphocytes.

NATURE

We invite applications for 1979 Writing Fellowships and Sabbaticals at *Nature*.

Writing Fellowships

There will be opportunities for two or three scientists or journalists to travel on our behalf and write feature articles and news stories based on their experiences. We see these fellowships as a means of extending the coverage of our news pages.

Sabbaticals

We shall also have two or three vacancies for scientists with a particular interest in editing or writing to spend a short period working with the *Nature* staff.

For further details and application forms please write to:

The Editor, *Nature*,
4 Little Essex Street, London WC2R 3LF

stating which scheme you are interested in.

The Physics of Vibration

Volume 1

A.B. PIPPARD

The study of mechanical, electrical and acoustic vibrations forms part of every basic course in physics and engineering. The book is intended to bridge the gap between what every scientist should know and what only dedicated experts in the field can understand. In this first volume the emphasis is on simple systems. Special attention is given to experiments illustrating the phenomena. The mathematical treatment is kept fairly simple, and wherever possible the reader is encouraged to visualize the behaviour of the system being studied.

Development of preparative techniques

Savile Bradbury

A History of Microtechnique. By B. Bracegirdle. Pp. 359. (Heinemann: London, 1978.) £22.50.

STUDENTS of the history of biological science have devoted considerable attention to the microscope, both to the mechanical development of the stand and to consideration of the resolving power of the optics. Very little by comparison has been written about the equally important topic of the preparation of material for examination. This is an essential part of microscopy, just as much as interpretation of the image produced by the instrument. A knowledge of the development of preparative techniques throughout the period in which the microscope has been in use is, therefore, desirable. Such information, amply provided in this book, helps the historian decide to what extent the performance of the actual microscope was a limiting factor in the acquisition of data, whether there was a conceptual barrier in the mind of the observer or, as may prove likely, it was a combination of these allied to poor and limited preparative procedures. For example, some early techniques for preparing soft tissues such as striated muscle fibres involved their immersion directly in hot balsam resin. As Dr Bracegirdle vividly illustrates, such a preparation dated from 1869 shows little recognisable detail even when viewed by a modern instrument, whereas a microscope of 1826 gives a clear and detailed image of a modern stained preparation of striated muscle. This practical approach characterises the book, whose author examined over 40,000 slide preparations (some 3,500 in detail) during the course of its preparation; in addition he studied microtomes and other instruments in various collections in this country and abroad, and indeed succeeded in operating many of them in accordance with the instructions provided by their inventors.

Although there is clear evidence that microscopes were used to examine biological material from the middle of the seventeenth century onwards, few details of the preparative approaches used at that time survive. This may perhaps be attributed to the fact that very little in the way of specimen preparation was attempted, most observers being content to examine with incident light the surfaces of objects or to study fine dissections at low magnifications. The author considers the early efforts at tissue preparation taking the early period as extending up to 1830. Only sporadic advances such as the invention of clearing agents, the mounting of thin sections of objects between talc covers in wood sliders and methods of micro-injection are to be found during this period. Obviously very few workers were taking microtechnique seriously and although the microtome, one of our most useful preparative tools in microtechnique, had been invented, only three examples (those of Custance, Hill and Adams) are recorded. This early period was, as the author comments, devoted to "specific advances of varying worth, not assimilated into an armoury of techniques generally in use"; some advances of great significance were however made, such as the introduction of the thin glass coverslip in 1789.

The century following the development of the achromatic microscope in 1826 was a time of great experimentation in microtechnique. Many and various reagents were tried, together with a host of embedding media. Some of these proved suitable—for example, paraffin wax and celloidin—and have survived into current use, whereas others—such as shellac, pulped paper, copal varnish and even tinfoil—have proved totally unusable and have disappeared from current practice.

Dr Bracegirdle devotes a long chapter to a discussion of the development of instrumentation in the nineteenth century. This chapter is largely an account of the microtome in its many and various phases and represents fascinating reading for a modern histologist.

The development of suitable chemicals and instruments for specimen preparation naturally led to the production of a large literature, much of it in German, during the nineteenth century. In his survey of this aspect of the subject, the author makes a very interesting comparison between the attitudes in England and on the continent of Europe between 1830 and 1910. In this country it was clear that the gifted amateur reigned supreme in the use of the microscope, pursuing the ultimate in resolution. The perfection of mounts (usually of diatoms) which allowed this seemed to be the aim. On the continent, especially in Germany, the value of the microscope was appreciated for the help that it could provide in elucidating the structure of both normal and diseased tissues. This was reflected in the rapid development of microscopic histology in the medical schools on the continent and by the contributions of workers such as Purkinje, Henle, Kölliker and Virchow.

This is a fascinating book, not only for the historian of science but also for the general histologist. It uses the history of microtechnique, as it developed in the nineteenth century, to pose the question whether many of the workers were not in danger of developing sheer technique and procedure at the expense of careful observation and experiment. Such a question is still relevant today.

The book is well produced and contains both name and subject indices, together with citations of over 1,000 original books and articles. The illustrations are all by the author; many are of material from his own extensive collection and are of a high standard, although some may find the placing of all the plates together in two adjacent signatures irritating.

Here we have a work which is sure to remain the standard reference in this field for many years to come. ☐

Savile Bradbury is Lecturer in Human Anatomy at the University of Oxford, UK.

Implications of artificial intelligence

Computer Revolution in Philosophy: Philosophy, Science and Models of Mind. By A. Sloman. Pp. 304. (Harvester: Brighton, UK, 1978.) Hardback £12.50; paperback £5.50.

THIS is an untidy, un-pompous, exciting, iconoclastic and exasperating book. The author, a professional philosopher as well as a research worker in artificial intelligence, is scathing about much of the prevailing methodologies of science, especially psychology and the social sciences generally, but his approach is perhaps best indicated by the following quotation in regard to philosophy:

> "I am prepared to go so far as to say that within a few years, if there remain any philosophers who are not familiar with some of the main developments in artificial intelligence, it will be fair to accuse them of professional incompetence, and that to teach courses in philosophy of mind, epistemology, aesthetics, metaphysics, and other main areas of philosophy, without discussing the relevant aspects of artificial intelligence will be as irresponsible as giving a degree course in physics which includes no quantum theory."

I am not competent to pass judgment on this sweeping prophecy, but there is no doubt that much interesting and convincing evidence and arguments tending to support it are presented. And on the way, a host of intriguing ideas and speculations, the majority of them not followed up alas, are thrown up.

Here, only a few examples can be given. Few philosophers of mind, not to mention neuropsychologists and experimental psychologists, have yet taken on board the insight provided by the fact that the same cognitive computer programme can be run successfully on different computers with quite different basic components and architecture. In other words, the specifically mental part of the system is in an important sense quite independent of the physical part (which of course is not to say that it can operate without a physical part). How this comes about, the notions of "virtual machine", and of levels of representation of the activity, connected by translators, compilers and interpreters; are of significance here. Consider also the implications for the doctrine of reductionism in the philosophy of science. If biological processes are computational processes running on a physicochemical system, then it is not necessarily the case that the nature of the physical world determines them.

Another important notion for the psychology and philosophy of mind is that of systems and mechanisms which have the property of "mutual recursion", that is, the relationships between any parts of the system are not confined to being disjoint, or part-whole or overlapping, but A can be a part of B which is at the same time a part of A, infinite regresses being avoided by stopping conditions. A characteristically fascinating aside of Sloman's here is the suggestion that neglect of this aspect of the mind might have profound implications for educational practice, in that cumulative educational programmes may be misguided: teachers should not be surprised at pupils getting things wrong when they are in the midst of learning a collection of mutually recursive concepts.

An example of how tantalising the author can be is in a chapter which contains a most original and searching analysis of the relationships between inferences of the analogical type, such as those using diagrams, in contrast to the more usual "logical" types. In the middle he makes the very interesting suggestion, without following it up at all, that the essence of our notion of causality may be the following: we talk of causes when we believe there is a representation of the process (in the analogical or other form) which enables the effect to be *inferred* in the broader sense of "logic" he has been developing.

In the hope that the above has given some sense of the flavour of the book, I shall now give a very brief summary of its contents. The first section deals with the aims of science and its relation to philosophy, putting the emphasis on the study of possibilities rather than the search for laws, and on conceptual analysis; it incidentally argues for a closer community of aims among philosophy, science *and* technology. The next section first attempts (in a very ambitious way) to sketch the structure of a mechanism of general intelligence. Three successive chapters then discuss intuition and analogical reasoning, learning about numbers and its bearing on the many and very diverse philosophical views on the nature of number, and perception as a computational process. It seems clear that the latter topic (in which Sloman's own research has been mainly concentrated) has been the one that has stimulated his thinking most. The final chapter discusses a large set of classical problems of philosophy in the light of our present understanding of artificial intelligence. These include universals, free will and determinism, mathematical knowledge, and aesthetic experience.

The main criticism one might make of the book, as has probably already occurred to the reader of this review, is that it tries to cover too much, with the result that it spreads itself too thin over the large majority of the issues it raises, and gives the impression of making sweeping judgments without sufficient backing. Sloman also has a maddening habit of producing frequently lists (sometimes as long as fifty items) of questions for the reader, most of which are indeed interesting and pertinent ones, but of few of them does he say anything more. In addition, nearly every one of them would probably require at least a day's solid thinking on the reader's part to get any benefit from. Also, future editions of the book (which I am confident will be called for) would be improved by correction of the inordinate number of misspellings, removal of howlers like attributing the explanation of the equivalence of mass and energy to the theory of *general* relativity, or stating that superconductivity was explained before it was observed, and also improving the legibility of the legends of the diagrams.

Mathematical approach to vectors

Vectors in Three-Dimensional Space. By J. S. R. Chisholm. Pp.293. (Cambridge University Press: Cambridge and London, 1978.) Hardback £15; paperback £4.95.

FEW can appreciate a Beethoven sonata by merely reading the score. It needs to be played by a gifted interpreter. Ease and familiarity with mathematical ideas come quickly to only a few. Many of us need to develop mathematical skills, but such skills are precariously based if we have no appreciation of the underlying mathematical logic. The interpreter is needed here too and J. S. R. Chisholm has demonstrated yet again that he has this gift. His book with Morris *Mathematical Methods in Physics*—now sadly out of print—was a model of its kind: clear and readable but paying attention always to the rigorous basis of the techniques. This new volume is aimed more directly at the mathematics undergraduate but it should be one of the 'lecturer's textbooks' for anyone teaching vectors to scientists and engineers.

Too often a mathematician's approach to vectors begins with an assertion of the general algebra of vector spaces, leaving the student to find analogies, if he can, with the world of three dimensional vector quantities in which he lives. This book maintains a healthy link with intuition. The axioms of vector space algebra are introduced from the start, but the three-dimensional geometrical interpretation of them takes up much of the text, with line-drawings to illustrate many of the arguments.

The relationship between vectors and vector-quantities is clearly explained. After establishing the axioms and discussing the products of vectors, there is a chapter in which geometrical examples are used to illustrate the relationship of vectors to matrices, tensors, the rotation group and general linear transformations. Vector calculus is introduced with a discussion of the geometry of curves and surfaces, going on to the the differential geometry of curves, surface integrals and volume integrals.

The final chapter on vector analysis introduces the div grad and curl of scalar and vector fields in three dimensions, with Stokes's Theorem (a more rigorous proof is given as an appendix), the Laplace operator and related theorems.

Most subsections of each chapter have worked examples and up to seven or eight problems. Short answers to many of the problems are given at the back of the book.

David J. Miller

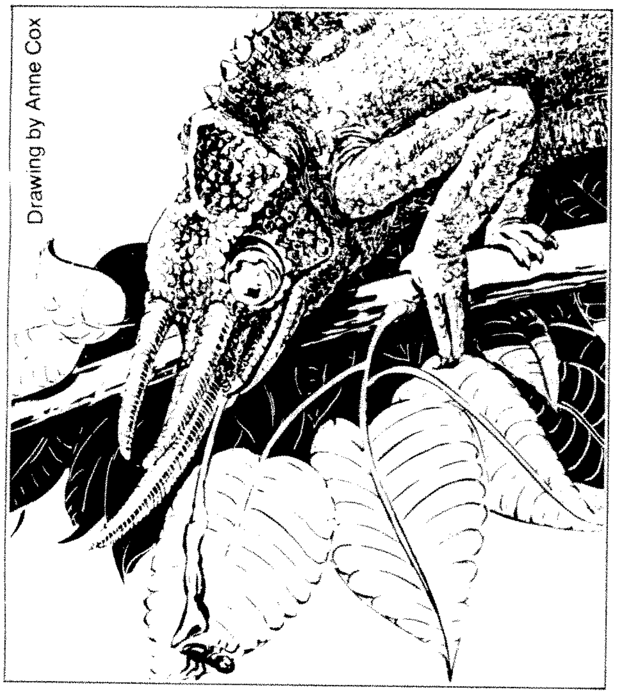
David J. Miller is Lecturer in Physics at University College, London, UK.

Princeton Books
Important, Definitive Pathbreaking

THE REPTILE EAR
Its Structure and Function

ERNEST GLEN WEVER

In this definitive work, Wever establishes the evolutionary importance of the reptile ear as the origin of the higher type of auditory apparatus shared by man and the mammals. Tracing the development of the auditory receptor in the living reptiles, he examines the use of a variety of mechanisms and principles of action by that receptor. 872 illus. £31.30



Drawing by Anne Cox

FOOD WEBS AND NICHE SPACE

JOEL E. COHEN

This book presents a new technique for obtaining a partial answer to an elementary question about niche space. The question is: what is the minimum dimension of a niche space necessary to represent the overlaps among observed niches? Cohen bases his technique on a relation between the combinatorial structure of food webs and the mathematical theory of interval graphs. *Monographs in Population Biology, 11.* Cloth, £8.80. Paperback, £4.35

CASTE AND ECOLOGY IN THE SOCIAL INSECTS

GEORGE F. OSTER and EDWARD O. WILSON

In this pathbreaking and far-reaching work, Oster and Wilson provide the first fully developed theory of caste evolution among the social insects. Of importance to the fields of entomology, general evolutionary theory, and sociobiology, this study goes beyond the concentration of previous researchers on the physiological mechanisms of the insects and focuses instead on the scale and efficiency of their division of labor. *Monographs in Population Biology, 12.* Cloth, £12.50. Paperback, £4.70

THE DYNAMICS OF ARTHROPOD PREDATOR-PREY SYSTEMS

MICHAEL P. HASSELL

A large part of theoretical ecology is devoted to understanding the basic components of predation. In his study of arthropod predator-prey systems, Hassell attempts to show how many of these components may be simply modeled in order to reveal their effects on the overall dynamics of the interacting populations. *Monographs in Population Biology, 13.* Cloth, £10.00. Paperback, £4.35

Introducing a new international monograph series in astrophysics for researchers and students

Edited by J. P. OSTRIKER

THEORY OF ROTATING STARS

JEAN-LOUIS TASSOUL

Ever since the first observations of sunspots in the early 17th century, stellar rotation has been a major topic in astronomy and astrophysics. Jean-Louis Tassoul synthesizes a large number of theoretical investigations on rotating stars. Drawing upon his own research, Prof. Tassoul also carefully critiques various competing ideas, some of which are evaluated here for the first time. *Princeton Series in Astrophysics, 1.* Cloth, £25.00. Paperback, £9.40

A History of Technology

Volumes VI and VII: The Twentieth Century c. 1900 – c. 1950: Parts I and II

Edited by Trevor I. Williams

These two volumes extend the five-volume *History of Technology* (1954–8), edited by Charles Singer, E. J. Holmyard, A. Hall, and Trevor Williams, which covers the period from the earliest times to 1900. The same guiding principles that were adopted for the earlier volumes have been retained for Volumes VI and VII, but greater emphasis has been placed on the economic, social, and political aspects in order to reflect their increasing importance in the twentieth century. The seven volumes will thus be an essential work of reference for all who are concerned with the development of technology – in the widest sense – and with the development of civilization.

Volume VI £25 Volume VII £27

Materials for Low Temperature Use

D. A. Wigley

This book discusses the factors influencing the mechanical and physical properties of metals, polymers, and composites below room temperature. Particular attention is devoted to the variation in their strengths and toughness. Data on these properties together with specific heats, thermal expansion coefficients, thermal conductivities, and compatibility with liquid oxygen of these materials are given in tabular and graphical form. Illustrated paper covers £2.95

Engineering Design Guides 26

Introduction to Materials Science

M. Deighton and J. A. Mead

This book is intended to emphasize the importance of the properties of materials in producing efficient designs. The terms used to describe the properties are defined and the appropriate test methods indicated. The significance of the various properties is discussed in general terms and metallic and non-metallic materials are compared. Illustrated paper covers £3.50

THE DRUGS HANDBOOK

Paul Turner and Glyn Volans

Many people other than doctors are involved in the operation of the health services, and so need to know something about the drug treatments that patients are receiving. The number of drugs in existence is already bewildering, and there is an even greater number of drug names, both trade and medical, which can only create a potentially lethal confusion. Moreover, even with access to a detailed reference book or a number of specialist works, precise information on a particular drug can be difficult to trace.

With these problems in mind, the authors have prepared a dictionary of drugs, arranged in alphabetical order of their medically approved names, with a trade names index. Each entry gives a brief description of the uses, actions and adverse effects of the drug – the sort of information that has been almost completely neglected in the non-specialist area of pharmacology. The book is presented, moreover, in a concise handbook format, for ease of carriage in a briefcase or capacious pocket. It should prove invaluable to anyone involved with the medical use of drugs.

'Concise, accurate and up-to-date' – *Miss W. E. Hector, Senior Lecturer, Queen Elizabeth College London.*

'This project strikes me as a very useful one. In particular the idea of an alphabetical list of medical names is a first class one . . .' – *a G.P.*

Biology of cancer

Cancer: A Problem of Developmental Biology. By G. B. Pierce, R. Shikes and L. M. Fink. Pp. 242. (Prentice-Hall: Englewood Cliffs, New Jersey, 1978.) £11.65.

READERS of that neglected masterpiece, *The Crock of Gold* (J. Stephens, Macmillan, 1928), will remember the philosopher's comment (to his wife) on the porridge — "Perfection is finality, finality is death. Nothing is perfect. There are lumps in it." Like the porridge, *Cancer: A Problem of Developmental Biology* has some indigestible lumps in it, but for all that it is a useful book for those for whom it is intended (graduate students). Don't be put off by the modest aims outlined (one hopes by the publisher) on the book cover:

> "The unifying theme of this modern approach to the study of tumors is development and neoplasia, treating carcinogenesis as a model of differentiation rather than as a neoplasmic entity alone. Coverage includes chapters devoted to the early development of neoplasms, tumors as caricatures of tissue renewal, structure and biochemistry of neoplasms, origin of neoplastic stem cells, carcinogenesis, genetics and neoplasia, controls, immunity and neoplasms, metastasis, and caner therapy.
>
> "An appendix concerning various types of tumours also is included. Among the features: Emphasizes the importance of cellular interaction in tumors, showing their cellular heterogeneity and control mechanisms; Presents an excellent introduction to the clinical phenomenology of cancer, placing more specialized aspects in a useful perspective; Organized into a logical, unified, and complete volume that includes the results of most recent research; Provides a complete bibliography of sources of more specialized information; Includes a chapter on therapy and some brief descriptions on the commonly studied tumors."

It does discuss many of these aspects but not in exhaustive detail, in its 199 pages of text. It does not compare in depth with Foulds' *Neoplastic Development* (Academic, 1969) which is still the best general introduction for the specialist to the biology of cancer. *Cancer: A Problem of Developmental Biology* is designed as an introduction to the field and in this I think that it achieves its purpose. For the student of biology with a general interest in cancer or a neophyte about to plunge into some highly specialised branch of cancer research, Pierce *et al.* will provide a useful reminder that there is more to cancer than molecules and also remind its readers that many of the findings of earlier workers are still relevant.

The faults of the book are superficial irritants rather than major defects, but nevertheless they are important, particularly in a book intended for students. The emphasis on the interests of the authors is understandable and not excessive, but the style sometimes grates. There has to be a better way of saying "respond negatively in terms of growth rate", particularly if one wants students to learn conciseness of expression.

A more serious criticism is concerned with minor but important inaccuracies and omissions. It is easy for a reviewer to carp over trifles, particularly when the authors are trying to compress a mass of information into a small space, but it is important not to mislead. A few examples will illustrate the point. The given definition of malignant tumours states that the malignant cells "are intrinsically dangerous because they are rapidly growing and quickly cause cachexia or they invade and metastasize. The intrinsically dangerous cells of malignant tumours invariably destroy their host unless they are either extirpated or killed". Although this is often so, the variation in growth rate of tumours is well known as is the whole concept of latency in tumours and of carcinoma *in situ*, which are in fact discussed elsewhere. The appropriate qualifying clauses would clarify the situation—important for those using the index to look for a definition of malignancy.

On the experimental side the authors suggest that transformation *in vitro* should produce a spectrum of cell lines, some tumour producing, some not—"an idea that has escaped attention", although they quote elsewhere a paper describing this very phenomenon. Sadly (as the paper is one of mine) it is given as a reference to work it does not describe.

In the general discussion on spontaneous transformation *in vitro* the authors fail to mention that this is predominantly a feature of some rodent cells and does not occur in species in which cells have been shown to have a finite lifespan as in Hayflick's experiments with human cells. In the section on genetics and neoplasia a statement is made that "recently, viral particles, similar to those of mouse mammary tumour virus, have been discovered in the milk of a high percentage of Parsi women" (Moore *et al.*, 1971), with the implication that these particles are true viruses and associated with a high incidence of breast cancer in these women. Many would no longer accept these findings. Other examples can be cited.

In spite of the criticisms this could be a useful book but it would be greatly improved by a more critical assessment of statements, definitions and references.

High performance liquid chromatography

High Performance Liquid Chromatography. Edited by J. H. Knox. Pp. 203. (Edinburgh University Press: Edinburgh, 1978.) £5.

THIS book is based on the material of a course on high performance liquid chromatography (HPLC) given in 1977 at the Wolfson Liquid Chromatography Unit, of which Professor Knox is the director. It represents a commendable attempt to put both the theory and practice of the subject on a firm physicochemical foundation, which the student can use to attack his own problems. The main theory of liquid chromatography is compressed into the relatively short chapter 2, followed by successive chapters on the familiar subdivision of chromatographic methods according to retention mechanism, adsorption, liquid-liquid partition, and ion-exchange (including ion-pair) and exclusion chromatography. These topics are very fully treated in the space available, and each chapter includes a table of the appropriate column packing materials commercially available.

Unfortunately the theoretical treatment of chapter 2 is rendered unnecessarily confusing by an unfamiliar notation in which V_m, the volume of eluent within the column, is taken to include both the liquid in the interstitial spaces between the packing particles and the liquid within the stationary phase pores. Although the pore volume cancels out in the definition of phase capacity ratio k' (equation 2.2, p5), it can only be valid as a mean value in the definition of linear flow velocity μ (equation 2.3). It leads to a new definition of zone capacity ratio k'' on p7, which is almost immediately abandoned on p8, leading to the more usual relationships of equations (2.12–2.17). The concept is again introduced in the treatment of the column resistance factor on pp9–10. This notation is all the more surprising, as the authors found it unnecessary in their excellent theoretical treatment in an earlier book.

Perhaps the most unfortunate result appears however in chapter 7 on exclusion chromatography, where an essentially simple concept is confused by the introduction of three definitions for the distribution ratio between the phases (p69). This chapter also illustrates the preoccupation of practitioners of HPLC with the exclusion chromatography of synthetic polymers, usually uncharged and soluble only in organic solvents. Although there is a brief reference to the exclusion chromatography of biopolymers in chapter 7, the treatment is in some respects misleading. For example, in the case of the gel media used with biopolymers, there *is* an increased zone dispersion, which *has* a good theoretical foundation in the polydispersity of retention sites (that is pores) in the stationary phase. This problem has been extensively discussed by Ackers and others. The consequent poor resolution has lead to the virtual abandonment of exclusion chromatography for the determination of the molecular weights of biopolymers by biochemists, who now favour electrophoresis in a continuous molecular sieving medium for this purpose. Also contrary to the impression given on p76, adsorption problems are still severe with many proteins on inorganic exclusion media. Polymer chemists seem to be indeed fortunate in the exclusion media available to them.

Chapters 8–10 give a very good account of the hardware of HPLC, columns, injection systems, pumps and detectors. Perhaps uniquely, this section also includes a discussion on the use of post-column reactor systems, which may be increasingly used in the future to increase both sensitivity and selectivity. Although the authors seem to be optimistic about the future development of many of the presently less common detectors, I feel that the current escalation in the cost of HPLC equipment may put many of these more sophisticated detectors out of the reach of any but specialised laboratories. From this aspect I consider the comparison of analytical methods in Table 11.1 rather biased in favour of HPLC, especially as regards specificity and cost. For example, a good radioimmunoassay can be at least as specific as an HPLC estimation, whereas instrumental costs have been overtaken by inflation during the time taken for publication of the book.

Applications of HPLC, particularly to pharmaceutical and clinical analyses, and a description of the Wolfson departmental course experiments conclude the book. The all-important topic of column packing is excellently covered, although late in the book.

As a comprehensive, modern and methodical treatment of all aspects of HPLC, this book has few rivals, especially at its very modest price.

C. J. O. R. Morris is Emeritus Professor of Experimental Biochemistry in the University of London, UK.

Molecular damage after radiation

Radiation Effects: ESR and ENDOR Analysis. By H. C. Box. Pp. 280. (Academic: New York and London, 1978.) $24.50.

THIS book describes the molecular damage which occurs in carboxylic acids, amides, amino acids, peptides, proteins, pyrimidines, purines and nucleic acids, when these substances are bombarded with high energy radiation. In addition to the immediate effect of the radiation, the secondary processes are described and some overall mechanisms are followed through. Most of this information is derived from a knowledge of what radicals are formed, in what yield, how quickly they react, and with what. It is the unique contribution of electron spin resonance (ESR) supplemented by ENDOR (a special form of nuclear magnetic resonance which uses the ESR signal as a means of detection), which makes this study possible.

The first five chapters describe the characteristics of the ESR and ENDOR methods. In this part of the book, hyperfine structure and g values are treated with fair rigour and the Hückel and INDO methods of computing spin densities are compared with each other and with experiment. The next five chapters are concerned with the radiation effects and mechanisms while the last chapter sets all this into perspective with current and projected work on: radiation modifiers which might be used in cancer treatment; conversion of solar energy into chemical energy; the relationship between radiation-induced carcinogenesis and DNA repair processes; and radiation damage in electron microscopy.

In general the book is well balanced between theory and experiment. It is well written and makes a fascinating account of our knowledge of the molecular events which follow irradiation of biological material. There are lots of well labelled chemical formulae and plenty of tables of data for reference purposes in the text and in appendices; these will make the book valuable for active workers in this field. The reviewer personally favours a slightly more experimental approach and would have preferred to see a few more actual spectra, particularly ENDOR spectra and more details of the assignments on these. Space could have been found at the expense of some of the mathematical detail in the early chapters which many readers more familiar with cell biochemistry might find difficult and unnecessary to follow.

Leading Researchers write for the Non-Specialist on

RECENT ADVANCES IN MATHEMATICAL BIOLOGY

Studies in Mathematical Biology

MAA Studies in Mathematics
Volumes 15 and 16
Simon Levin, Editor

The widely respected series **MAA Studies in Mathematics** has long published expository papers on topics at the research frontiers written for a broad mathematical audience. *STUDIES IN MATHEMATICAL BIOLOGY* expands that tradition; this two-volume set is written also for the mathematically prepared life scientist Eighteen leading researchers write of recent work in the active field of mathematical applications, providing an authoritative yet refreshingly accessible sampler of advances and current research directions. These new books will be useful for seminars, independent study projects, and supplementary reading for all who are interested in the contributions of mathematics and biology.

Part I, Cellular Behavior and Development of Pattern. Papers by John Rinzel, Jack Cowan and G. B. Ermentrout, Michael Arbib, Lee A. Segel, Nancy Kopell, E. C Zeeman, Stuart Kaufman, Arthur T. Winfree, J. M. Guckenheimer.

Volume 15; xiv + 315 pages + index. Hardbound. List $16.00.

Part II, Populations and Communities. Papers by Robert M. May and Robert H. MacArthur, Donald Ludwig, S. I. Rubinow, George F Oster, Simon A Levin, W. J. Ewens, Samuel Karlin, Thomas Nagylaki.

Volume 16, xx + 308 pages + index. Hardbound. List $16 00.

Special price for the two-volume set: $27.00

Order your copies now from: MAA, 1529 Eighteenth St., N.W., Washington, D.C. 20036. (Orders from Europe, Africa, Middle East should be sent to. John Wiley and Sons, Ltd., Baffins Lane, Chichester, West Sussex, P019 1UD England Prices slightly higher.)

COLD REGIONS SCIENCE AND TECHNOLOGY is an international journal dealing with the scientific and technical problems of cold environments, including both natural and artificial environments. The primary concern is with problems related to the freezing of water, and especially with the many forms of ice, snow and frozen ground. The journal is intended to serve a wide range of specialists, providing a medium for inter-disciplinary communication and a convenient source of reference.

Emphasis will be given to *applied science,* mainly in the physical sciences, with broad coverage of the physics, chemistry and mechanics of ice, ice-water systems, and ice-bonded soils. Relevant aspects of *earth science* and *materials science* will also be primary concerns.

Technological aspects are expected to be dominated by research, development and professional practice in *engineering.* This includes traditional major specializations of engineering (military, civil, mechanical, mining, electrical), together with other engineering subdivisions (e.g. hydraulic, agricultural, highway, sanitary, petroleum, ocean, airport). Coverage will also embrace engineering geology, architecture, meteorology, hydrology, forestry, exploration geophysics, naval architecture, and so forth.

Call for Papers

Authors are invited to submit suitable manuscripts, in triplicate, to the Editor, Dr. Malcolm Mellor. "Instructions to Authors" are available from the publishers. Fifty reprints will be supplied free of charge. There are no page charges. The principal language of the journal is English, but papers in French and German are acceptable.

For further detailed information or a free specimen copy, please contact the publisher.

Microbiological Research Establishment

Microbial Products

Azurin
Minimum Quantity 100mg @ £280
Isolated from **Pseudomonas aeruginosa** this product is pure ($A_{625}/A_{280} = 0.58$). Supplied as a solution which is stable when stored at −20°C.

Micrococcal Nuclease
Minimum Quantity 10^{6} units @ £336
(5×10^{6} units @ £1300, 10^{7} units @ £2200)
Isolated from **Staphylococcus aureus** (Foggi). Supplied as a lyophilised powder with a minimum specific activity of 8000 U/mg protein. Stable at +4°C.

Staphylococcal Immunoadsorbent
Minimum Quantity 2.5 litres @ £200
Heat killed, formaldehyde treated cells of **Staphylococcus aureus** (Cowan Str. 1) washed three times with buffer. Supplied as a 10% wet weight/volume suspension in 150 mM NaCl, 40 mM potassium phosphate, pH 7.2 containing 0.02% NaN_3. Stable at +4°C.

Superoxide dismutase
Minimum Quantity 100mg @ £280
Isolated from **Bacillus stearothermophilus** and purified to homogeneity with a specific activity of 2900 U/mg protein. Supplied as a solution in 20 mM potassium phosphate, 50% glycerol pH 6.8. Stable at −20°C or for one year at +4°C.

Transfer RNA
Minimum Quantity 2 grams @ £210
Isolated from **Escherichia coli** K12 CA265 as mixed species tRNA containing about 50% chargeable tRNA as judged by aminoacylation. Supplied as a suspension in 70% ethanol. Stable at −20°C.

The listed products are offered at the quoted sterling prices, which remain firm until 1 April 1979 subject to availability. Prices include packing and delivery on UK orders, which are subject to VAT at ruling rates. Overseas orders are subject to transport charges at cost. For listed items please send your official order and delivery instructions to the .

Circle No. 15 on Reader Enquiry Card

obituary

Ivor Isaac

IVOR ISAAC, Professor of Botany in the University College of Swansea and Vice-Principal of the College from 1973 to 1977 died on 4 August 1978 at the age of 63.

He was a Swansea man born, bred and educated in the City. From Dynevor School he entered the University College of Swansea in 1934 and graduated with first class honours in botany. Isaac then trained as a teacher and taught for a short time afterwards but in 1940 he was awarded an A.R.C. Scholarship to work at Cambridge on plant pathology under the supervision of Professor F. T. Brooks. Two years later, Isaac moved to East Malling Research Station as a plant pathologist where he continued his studies for a Cambridge PhD on the plant wilt diseases caused by the fungus *Verticillium:* these studies determined Isaac's subsequent career.

After three years at East Malling, Isaac returned to school teaching at Cheltenham but in 1947 he was appointed Senior Lecturer in Biology at Acton Technical College which was later developed into Brunel University. While there, Isaac was responsible for the planning of the new Department of Biology at Brunel However, in 1950 the opportunity came to return to Swansea first as lecturer in botany and subsequently as reader and professor in the University College. There Isaac played his full part in the development of a rapidly growing department and he pursued his researches on *Verticillium* wilt diseases so successfully that he soon became recognised internationally as one of the leading experts on this important pathogen.

Isaac's early work centred on clarification of the taxonomy of *Verticillium* isolates. At that time, there was considerable confusion because it was not clear whether the two most destructive pathogens in the genus viz. *V. albo-atrum* and *V. dahliae*, were forms of the same organism or were two distinct species. By using morphological, physiological and pathological criteria, Isaac established convincingly that these organisms are distinct species. A distinguished fellow worker wrote subsequently that this work brought order out of chaos.

Isaac continued, with the help of research students, to study many different aspects of the vascular wilt diseases caused by *Verticillium* both in the United Kingdom and overseas. The studies were extended to a wide range of host plants often of great economic importance, such as lucerne and potato. The studies resulted in a continuing series of papers covering the ecology and survival of the fungus in the soil, the etiology of the disease, methods of control and the prevention of dissemination.

Isaac's reputation as a plant pathologist led to invitations to visit and advise in several countries including Italy, Malaya, India and the United States. Shortly before his death he was collaborating closely with the U.S. Department of Agriculture on an outbreak of *Verticillium* wilt on American lucerne crops. He served on several committees concerned with plant pathology and he played a leading part in the establishment of the first International Conference on *Verticillium*.

Isaac was no narrow academic. In his early years he was a very considerable soccer player and he captained both the Cambridge University team and the war-time combined Oxford and Cambridge XI. In later years in Swansea he was always deeply concerned with adult education and he frequently taught extra-mural courses himself. He was a man with many friends. His warm sympathetic personality was combined with high academic ability and clarity of thought; these qualities were much appreciated by colleagues and by students at all levels. He is survived by his wife Catherine, by three sons and a daughter.

J. M. Milton

D. W. Kent-Jones

DR DOUGLAS WILLIAM KENT-JONES, O.B.E., F.R.I.C., died peacefully in Ealing on 31 August 1978, aged 87. He was one of the pioneers of the application of science to cereal technology and was recognised internationally as an authority on cereal chemistry. Indeed his book *Modern Cereal Chemistry* testifies to his immense knowledge of his subject.

In the 1914–18 war he served in the Royal Fusiliers, the Special Brigade of the Royal Engineers and the Royal Flying Corps. It was during this time he claimed he learned his great capacity for getting on with others, and it was this capacity that spurred him throughout his long and active life to give generously of his time to many professional bodies. Thus he was honorary Treasurer of the Royal Institute of Chemistry (1946–53) and its President from 1955–57. He was honorary secretary of the food division of the Chemistry Section of the International Union of Pure and Applied Chemistry, Chairman of the Council of the British Industrial Biological Research Association (1966–70) and its President from 1970–72. In 1971 he was awarded the biannual Gold Medal of the Society of Chemical Industry and in 1974 he received the O.B.E. for his services to the food industry.

During the greater part of this time he was (until he reached the age of 75) the senior partner of the highly successful analytical and consulting chemists, D. W. Kent-Jones and A. J. Amos. After the 1914–18 war he had been chemist, and later director, of a firm in Dover associated with the milling and baking industries and in 1931 he formed the practice, specialising in cereals, first from laboratories in Dover, later in Ealing, and finally the spacious and well-equipped premises in Dudden Hill Lane, London

He learned his baking by working in small bakeries after his days work, and in 1935 published *The Practice and Science of Breadmaking*. From 1926–45 he was the Chief Examiner of Breadmaking to the City and Guilds of London Institute. During 1930–39 he travelled and lectured extensively, becoming involved in Procea Products Ltd. when in the Antipodes and when the Company was formed in the UK he became a director, and finally Chairman, retiring in 1965. In 1938 he was awarded the Belgian Affront medal, and was made Professor *honoris causa* of the Institute des Industries de Fermentation In 1947, at the request of the Bread Manufacturers of New South Wales, he advised on the setting up of the Bread Research Institute of Australia.

Wherever he went he was interested in measuring the qualities of flour and their relation to bread, cake and biscuit baking characteristics and he published many papers on this subject. In 1949 he gave the Cantor Lectures of the Royal Society of Arts. He is well known for the development, with his colleague W. Martin, of the Flour Colour Grader, and the instrumental techniques now used in determining flour quality owe much to him, and his partner's enthusiasm for technological innovations.

Kay-Jay (as he was mainly known) and his wife had no children, but within the family he gave great affection and loyalty; so too did he to his many professional and close friends. He found great joy in the companionship of the Savage Club and after retirement, through being given honorary memberships of the Flour Milling and Baking Industries Research Association, the British Industrial Biological Research Association, the American Association of Cereal Chemists and the Bread Research Institute of Australia, as well as the honorary Fellowship of the Institute of Food Science and Technology.

J. B. M. Coppock

D. M. Dring

Dr D. M. Dring, Mycologist, Plant Pathologist and Quarantine Officer at the Royal Botanic Gardens, Kew, died suddenly after a brain haemorrhage on 26 July 1978 at the age of 46.

Born in Peterborough he went to Exeter University and obtained an external London B.Sc. (1953). From 1953 to 1956 he was an Andrew Simons Scholar at the same University where he worked on *Mycosphaerella* disease of cauliflower for which he was awarded a Ph.D. (1958).

This led to a wider interest in plant pathology and from 1956 to 1960 he was plant pathologist to the government of Ghana with an additional duty to act as Director of the Botanic Garden at Aburi. From 1960 to 1961 he was Agricultural Officer to the United Nations Food and Agricultural Organisation in West Africa working on Kaincope disease, spending much time in the Camerouns and Togo. During his travels he became interested in the larger tropical fungi, especially those bizarre and brilliantly coloured Gasteromycetes belonging to the Phallales.

On return to the United Kingdom he was awarded a Senior Research Fellowship to work for three years at the Royal Botanic Gardens, Kew, on the fungi he had collected in West Africa. Later in 1965, he joined the Scientific Civil Service as a Senior Scientific Officer and became a permanent member of the staff at Kew, where his unique knowledge of plant pathology combined with an interest in taxonomy of higher fungi were invaluable. Indeed his experience of tropical plant pathology ideally fitted him for the job of Officer-in-Charge of quarantine in a rapidly expanding unit, and in 1973 he was seconded briefly to the Government of Fiji to advise on the setting up of a quarantine station.

Donald Dring will be remembered for his publications on Gasteromycete taxonomy which established him as one of the world authorities on this difficult group of fungi. These contributions included floristic studies of the species occurring in tropical Africa and Israel. He also published, with Dr H. Kreisel, a monograph of the genus *Morganella*. However, his chief interest lay in the elucidation of the complex structure, inter-relationships and taxonomy of the phalloids, especially of the family Clathraceae. His magnum opus *Towards a natural re-arrangement of the family Clathraceae* was in an advanced stage of preparation at the time of his death and it is hoped to publish this in due course.

Another of his many scientific activities involved giving a stimulating annual course of lectures on mycology to the student gardeners at Kew. He also took a keen interest in the affairs of the British Mycological Society and served as a co-editor of their Transactions from 1978–1971, and for part of that time as senior editor. His editorial expertise also led to his serving on the editorial board of the *Kew Bulletin*. He also served on the Council of the Systematics Association.

Donald Dring was a congenial colleague who was always happy to take part in and contribute to social occasions. He had a great interest in antiques and enjoyed restoration of period furniture. He leaves a widow, Vivienne, and two daughters.

Derek A. Reid

A. S. Jack

Anthony Jack, member of staff of the MRC Laboratory of Molecular Biology, Cambridge, died of a heart attack on 14 July 1978 at the age of 30.

Born in Newcastle, he was educated at Leeds Grammar School and at Peterhouse, Cambridge, which he entered as an Exhibitioner in 1966. After getting a First in Part II of the Natural Sciences Tripos (Crystallography), he went on to the MRC Laboratory of Molecular Biology to work for a PhD which he received in 1972. He spent two years on a Jane Coffin Childs Research Fellowship at the Gibbs Laboratory, Harvard University, and returned to the MRC Laboratory in 1974 as a junior member of staff.

Tony Jack's research work centred on the structures of large biological molecules and methods of solving them by X-ray analysis. Although a skilful experimenter when the occasion demanded, he was, by temperament and aptitude, more of the analytical type of macromolecular crystallographer, more intrigued by the way to the solution than by the results of the solution itself. Thus it was no coincidence that he was attracted to problems which were non-orthodox at the time. His PhD thesis, following work initiated by Blow, Rossmann and Crowther, deals with the problem of how to use for phase determination the redundant information present in the X-ray intensities of structures made up of many subunits. He solved a practical problem, namely a two-dimensional projection of the structure of the protein disk of tobacco mosaic virus, thereby pointing the way to the full solution of three-dimensional virus structures.

In the laboratory of S. C. Harrison at Harvard, he played a key role in the earlier stages of the X-ray work on tomato bushy stunt virus, among other things, using the low resolution structure reconstructed from electron micrographs to locate the heavy atoms used in the isomorphous replacement analysis.

On his return to Cambridge, Jack turned to the problem of refining the structure of the monoclinic form of tRNA, solved there earlier. This analysis, as well as settling the details of the tertiary interactions, led to the discovery of certain new correlations in nucleotide conformation and showed up the magnesium and spermine binding positions in the molecule. In an extension of this work on tRNA, Jack, together with M. Levitt, developed a particularly rapid and powerful method of refinement, which combines X-ray results and energy analysis. The method has been applied successfully to a number of proteins as well, and bids to become widely accepted.

Almost none of his friends or colleagues knew of Tony Jack's heart condition. Though quiet by nature, he was ever energetic and worked with astonishing rapidity. He was a man of varied interests. As an undergraduate he played in the 'Pineapple Truck' pop group, having built his own bass guitar. He was widely read in 18th century English literature, he collected its authors and was a stout Johnsonian. He is survived by his wife, Sharon Bellard, a chemical crystallographer, whom he met at Harvard.

A. Klug

announcements

Meetings

31 January–1 February, **Computerisation of Animal Toxicology Study Data,** Virginia (Dr Thomas Davis, Metpath Inc, 1 Malcolm Ave, Teerboro, New Jersey 07608.

25 February–2 March, **Fundamentals of Quantum Theory and Quantum Field Theory,** Palm Coast, Florida (Director, Sanibel Symposia, Williamson Hall, University of Florida, Gainesville, Florida 32611).

6–10 March, **Asteroids and Planets X,** Tuscon (T. Gerhrels, Lunar and Planetary Laboratory, University of Arizona, Tuscon, Arizona 85721).

9–10 March, **11th Stadler Genetics Symposium,** Columbia (G. P. Rédei, 117 Curtis Hall, University of Missouri, Columbia, Missouri 65211).

12–16 March, **Tunnelling '79,** London (The Institution of Mining and Metallurgy, 44 Portland Place, London W1, UK).

13 March, **Topics of Organic Chemistry —Protecting Groups,** London (Assistant Secretary, Society of Chemical Industry, 14 Belgrave Square, London SW1, UK).

20 March, **Toxic Considerations in Fats and Oils Products and Derivatives,** New Jersey (George Willhite, American Oil Chemist's Society, 508 S Sixth St, Champaign, Illinois 61820).

27 March–10 April, **The Mechanism of Continental Drift and Plate Tectonics,** Newcastle (W. F. Mavor, School of Physics, The University, Newcastle upon Tyne, UK).

28–30 March, **Nuclear Structure and Elementary Particle Physics Conference,** Birmingham (Dr J. M. Nelson, Dept of Physics, University of Birmingham, PO Box 363, Birmingham, UK).

30 March, **Metal Toxicities,** Aberdeen (The Nutrition Society, Chandos House, 2 Queen Anne St, London W1, UK).

2–4 April, **Vacuum Processes for the Electronics Industry,** Sussex (Carole Meads, Sira Institute Ltd, South Hill, Chislehurst, Kent, UK).

2–6 April, **Diagnostic Methods in Clinical Virology,** Guildford (Dr S. A. Volkers, Flow Laboratories Ltd, Irvune, Ayrshire, UK).

9–11 April, **Flammability of Fibres and Textiles,** Salford (The Administrative Assistant, Room 110, Registrar's Dept, University of Salford, Salford, UK).

19 April, **Gas Injection into Liquid Metals,** Newcastle (Dr A. E. Wraith, Dept of Metallurgy & Engineering Materials, The University, Newcastle upon Tyne, UK).

19–21 April, **The Lower Swansea Valley: Retrospect and Prospect,** Swansea (Dr R. D. F. Bromley, Dept of Geography, University College of Swansea, Swansea, UK).

24 April, **Aspects of Xylem Differentiation,** Reading (Dr J. R. Barnett, Plant Science Laboratories, University of Reading, Whiteknights, Reading, Berks, UK).

24 April, **Carbohydrate Metabolism in Ruminants,** London (The Nutrition Society, Chandos House, 2 Queen Anne St, London W1, UK).

21–23 May, **4th International Symposium on Cooley's Anemia,** New York (Conference Dept, The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021).

24–27 May, **Polyploidy: Biological Relevance,** Washington (Walter H. Lewis, Dept of Biology, Washington University, St Louis, Missouri 63130).

22–25 May, **13th International Leucocyte Culture Conference,** Ottawa (K. Charbonneau, Executive Secretary, National Research Council of Canada, Ottawa, Ontario, Canada K1A 0R6).

30 May–1 June, **33rd Annual Frequency Control Symposium,** New Jersey (US Army Electronic Research & Development Command, Delet -MF, Fort Monmouth, New Jersey 07703).

13–16 June, **37th Annual Meeting of the Scandinavian Radiological Society,** Stockholm (Tor Drevvatne, NR 37 c/o RESO Kongresstjänst, S-105 24 Stockholm, Sweden).

8–14 July, **11th International Congress of Biochemistry,** Toronto (K. Charbonneau, Executive Secretary, National Research Council of Canada, Ottawa, Ontario, Canada K1A 0R6).

9–13 July, **5th International Workshop on Gene Mapping,** Edinburgh (Prof. H. J. Evans, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh, UK).

16–20 July, **6th International Conference on Energy Transfer,** Rodez (Mrs M. Hueyz-Aubert, Groupe de Recherche Thermiqued, Ecole Centrale, Grand Voie de Vignes, Chatenay-Malabry 92290, France).

17–23 July, **4th Annual Advanced Institute in Methods of Immunological Diagnosis,** Michigan (Noel R. Rose, Dept of Immunology and Microbiology, Wayne State University School of Medicine, 540 East Canfield, Detroit, Michigan 48201).

23–27 July, **Plant Membrane Transport Workshop,** Toronto (Dr J. Dainty, Dept of Botany, University of Toronto, Toronto, Ontario, Canada M5S 1A1).

APPOINTMENTS VACANT

INTERNATIONAL LIVESTOCK CENTRE FOR AFRICA

One of the international research institutes funded by the Consultative Group on International Agricultural Research, is expanding Information and Training Services and invites applications from qualified and experienced personnel in

- **AGRICULTURE TRAINING**
- **CONFERENCE ADMINISTRATION**
- **EDITORIAL SERVICES**
- **LIBRARY MANAGEMENT**
- **HEAD OF PUBLICATIONS**
- **SCIENTIFIC TRANSLATION** (English–French)

The majority of the staff to be recruited will be based in Addis Ababa, Ethiopia, though some can expect to be based at regional centres in Nairobi, Kenya and Bamako, Mali. Some staff members are required to direct activities in the field of information and training, while others are required to fulfill specific functions within the areas listed.

Salaries will vary according to post and experience, but are generally competitive in the range US$10,000 to US$32,200 per annum. An outstanding applicant, appointed to a position of wide responsibility, could be offered a salary exceeding US$32,200 per annum. Most international staff in I.L.C.A. are required to be bilingual in English and French.

Most appointments will be made on a two-year contract, though applications from those wishing a short terms contract (6 or 12 months) are also invited.

Conditions of service include annual home leave, furnished accommodation and favourable family and cost of living allowances. International staff are accorded some diplomatic privileges (such as immunity from local taxes, etc.) enjoyed by similar international organisation in its centres.

Applications should be submitted in writing to:

The Personnel Officer
I.L.C.A.
P.O. Box 5689
ADDIS ABABA
Ethiopia

to arive before February 28 (quoting ref. ITS).

9138(A)

RESEARCH OFFICER/ TECHNICIAN

required by the Medical Research Council Unit at Hammersmith Hospital. The work will consist mainly of biochemical changes in cellular systems after exposure to radiation and other toxic hazards. Previous experience of biochemical techniques would be advantageous. Candidates should possess a degree or equivalent qualification in a relevant discipline. Salary, according to age and experience, in the range £3,615 to £5,256 (inclusive of London Weighting).

Please write, giving qualifications and curriculum vitae, to: Miss A. Pires, M.R.C. Cyclotron Unit, Hammersmith Hospital, Ducane Road, London W12 0HS.

9119(A)

McGILL UNIVERSITY POSTDOCTORAL RESEARCH FELLOW

Applications are invited for a Postdoctoral Research Fellow to work with Dr D. G. Osmond on cellular aspects of the immune system, particularly the differentiation and potentials of lymphocyte populations produced in the bone marrow. The position is available from April 1, 1979 for up to two years post Ph.D. at a salary of $11,600 to $12,720. A background in general cytology, cellular immunology or experimental hematology is desirable. Applications, including curriculum vitae and names of two referees, should be sent to Dr D. G. Osmond, Department of Anatomy, McGill University, 3640 University Street, Montreal, PQ, Canada H3A 2B2. Telephone (514) 392-4898.

9092(A)

UNIVERSITY OF SHEFFIELD

DEPARTMENT OF BIOCHEMISTRY

TECHNICIAN (Grade 3)

required to assist in an S.R.C. supported project for a period of three years on biochemical and biophysical aspects of plant photosynthesis. Previous laboratory experience is expected and familiarity with spectrophotometric/fluorometric instrumentation would be an advantage. The successful applicant will be able to learn a wide variety of laboratory techniques and will be encouraged to work with minimal supervision. Commencing salary £2,688 per annum (under review).

Please write giving the names of two referees, to the Administrative Officer (Personnel), (Ref. S1147/N), The University, Sheffield S10 2TN.

9105(A)

ROTHAMSTED EXPERIMENTAL STATION

HARPENDEN, HERTS AL5 2JQ

SURVEY DEVELOPMENT OFFICER (ENTOMOLOGY)

required to develop ways of applying and disseminating insect survey information for pest advisory purposes. The appointee will extend the usefulness of the present Rothamsted system for national and regional monitoring/forecasting of pests, initially aphids, and promote its adoption.

The work will require the imaginative application of modern analytical and communications methods applied with a keen interest in crop protection.

Qualifications: 1st or 2(1) hons. degree in Agriculture or Applied Entomology, with at least two years' relevant experience in either agricultural data processing, economics, or communications, and/or crop protection and advisory work.

Appointment in grade of Higher Scientific Officer (£4,101 to £5,448) or Senior Scientific Officer (£5,154 to £6,898). At least four years' postgraduate research or other approved experience is required for appointment as S.S.O. Non-contributory superannuation.

Apply in writing to the Secretary, giving names and addresses of two referees, and quoting Ref. 384 by February 1, 1979. Further details on request.

9106(A)

The School of Medicine of the STATE UNIVERSITY OF NEW YORK at Stony Brook

is conducting a search for a Chairperson of the Department of Neurosurgery who will be responsible for developing an academic programme and a patient care programme at the School and at the University Hospital. Address inquiries to: Leonard E. Meiselas, M.D., Chairman of Search Committee, SUNY at Stony Brook, Long Island, N.Y. 11794. Equal Opportunity/Affirmative Action Employer.

9107(A)

UNIVERSITY OF THE WITWATERSRAND AND SOUTH AFRICAN INSTITUTI FOR MEDICAL RESEARCH,

Johannesburg, South Africa

CHAIR OF TROPICAL PATHOLOGY IN THE SCHOOL OF PATHOLOGY

Applications are invited for appoin ment to the above post of the join staff of the University and the Inst tute, in the School of Pathology. Dutie are to be assumed as soon as possibl

Salary attached to the appointmen will be up to a maximum of R19,20 per annum. Details are explained i the information sheet.

Intending applicants should obtai the information sheet attached to thi post from the Registrar, University c the Witwatersrand, Jan Smuts Avenu Johannesburg, 2001, South Africa, wit whom applications should be lodge not later than January 31, 1979.

9099(A)

READVERTISEMENT

Institute of Obstetrics and Gynaecology UNIVERSITY OF LONDON

Queen Charlotte's
Maternity Hospital
Goldhawk Road
London W6 0XG

Applications are invited for the post of

SCIENTIFIC PROGRAMMER

GRADE 1B

at the Institute of Obstetrics an Gynaecology, Queen Charlotte Maternity Hospital. Salary scale: £3,38 to £5,604 plus £450 London Weightin Allowance. The primary function c this post is to support a new PDP1 programmable remote-job-entry term nal connected to the University CD computer installation. The work wi involve an interesting variety of sof ware development, plus the oppo tunity of real-time programming fc mass spectrometry. The successfi applicant will work in a small, live research department with a lot c scope for inventive development.

A scientific background would t an advantage and registration for higher degree would also be a po sibility.

Further details may be obtain from the Secretary, Institute c Obstetrics and Gynaecology, Chels Hospital for Women, Dovehouse Stree London SW3 6LT.

Applications, together with cu riculum vitae and the names ar addresses of two referees should t sent to: Dr G. S. King, Chemic Pathology Department, Que Charlotte's Maternity Hospital, Gol hawk Road, London W6 0XG, t Monday, February 5, 1979.

Readvertisement is necessary due the failure of the appointed person take up the position, previous app cants who wish to be re-consider should notify Dr King. 9095(A)

UNIVERSITY OF DUBLIN
Trinity College

LECTURER IN BOTANY

Applications are invited for the above post in the Department of Botany, Trinity College, Dublin, from candidates with special interests in Taxonomy/Systematics *or* Population Ecology. A knowledge of the Irish flora and an interest in field botany in Ireland would be an advantage.

Salary Scale: £4,232 to £8,321. Appointment is likely to be made within the range £4,232 to £4,680. There is a non-contributory pension scheme.

Application forms and further particulars relating to the post may be obtained from:

The Establishment Officer
West Theatre
Trinity College
Dublin 2

to whom completed applications should be sent by not later than January 31, 1979. 9067(A)

UNIVERSITY OF DUNDEE
DEPARTMENT OF BIOLOGICAL SCIENCES

Applications for a post of

LECTURER

in the above Department are invited from bacteriologists, especially those with a broad bacteriological background and with research interests in molecular genetics.

Salary scale £3,883 to £7,754, with initial placing depedent on qualifications and experience. Superannuation under USS (or continuation of FSSU). Grant towards removal expenses to Dundee.

Applications (six copies), containing the names and addresses of three referees, should be sent by January 30, 1979, to The Secretary, The University, Dundee DD1 4HN, from whom further particulars are available. Please quote Reference EST/74/78J.

OVERSEAS DEVELOPMENT

KNOW-HOW: vital to developing countries

2 Experts (Resident Advisers) in Coastal Aquatic Biology

INDONESIA

At the University of Diponegoro to assist in development of courses, preparation of lectures and use of scientific equipment; to advise on suitability of local staff for UK training. Applicants should be well qualified (equivalent to UK University lecturer) with research interests in some aspect of aquatic biology, preferably marine and/or fisheries biology. Teaching experience is important and evidence of the ability to assist in the development of teaching programmes in a range of different biological topics.

Appointments 18 months initially, with possibility for extension. Salary (UK taxable) according to qualifications and experience plus variable tax free overseas allowance currently in range £1,890 to £4,080 p.a. Superannuation rights may be safeguarded. (Ref 317 X).

Cotton Entomologist

TANZANIA

Required as a part of a 7 man Cotton Research and Development Team to plan and implement the Cotton Research Programme operated from the Agricultural Research Institutes at Ukiriguru and Ilonga. The entomologist will plan and implement the cotton entomology programme. Main work is comparison of insecticides and application methods, including ultra-low volume application, for control of cotton pests, mainly American ball worm, cotton stainers and aphids. The economics of cotton spraying and an examination of the factors affecting yield responses currently being achieved by farmers are also to be studied. Applicants should possess agricultural science degree and have at least 3 to 5 years' relevant postgraduate experience.

Appointment 2 years. Salary (UK taxable) in range £4,700 to £6,500 p.a. plus a tax free overseas allowance in range £1,400 to £3,370 p.a. (Ref E331 X).

The posts are wholly financed by the British Government under Britain's programme of aid to the developing countries. In addition to basic salary and overseas allowances other benefits normally include paid leave, free family passages, children's education allowances and holiday visits, free accommodation and medical attention. Applicants should be citizens of the United Kingdom.

For full details and application form please apply, quoting reference stating posts concerned, and giving details of age, qualifications and experience to:—

Appointments Officer,
MINISTRY OF OVERSEAS DEVELOPMENT,
Room 301, Eland House,
Stag Place, London SW1E 5DH.

HELPING NATIONS HELP THEMSELVES

THE OPEN UNIVERSITY
FACULTY OF SCIENCE

RESEARCH ASSISTANT IN BIOLOGY

A Research Assistant is required for a project on the development of social behaviour in marmosets. The work will involve systematic observation of the social behaviour of captive groups of marmosets, computer-based analysis of behavioural data, and assisting in the supervision of the marmoset colony. Applicants should have at least a good first degree in Biology Previous experience in ethological and/or primatological research and computer-based analysis of behavioural data would be an advantage

The appointment is for three years. Ref: 3719

RESEARCH ASSISTANT/ FELLOW IN BIOLOGY
(Drosophila Research Project)

Applications are invited for a temporary research position with the Drosophila Research Project in the Biology Discipline at the Open University. The project is to investigate the role of physiological adaptation in evolution, under the direction of Dr. Mae Wan Ho. Candidates should have a good first degree in a relevant area, and some experience in population genetics, preferably of Drosophila. A relevant PhD degree will be an advantage

This post is available initially for one year, with the possibility that the grant may be renewed. Ref: 3721

Commencing salary will be within the range £3,384 to £3,883 per annum on the 1B scale for Research and Analogous staff, with USS benefits.

PLEASE QUOTE THE REFERENCE NUMBER OF THE POST IN WHICH YOU ARE INTERESTED

Application forms and further particulars are available from The Recruitment Office (JD3719/2), The Open University, P.O Box 75, Walton Hall, Milton Keynes, MK7 6AL or telephone Milton Keynes 63404: there is a 24 hour answering service on 63868.

Closing date for applications: 25 January 1979.

9103(A)

Lesotho
Forest Research Officer
Up to £8,590 plus allowances

The successful candidate will initiate and carry out research into the silvicultural problems of Lesotho. This will involve the evaluation of various methods of soil preparation, conducting trials on various species, the collection and analysis of data, and investigation of management systems.

Candidates should hold a degree in forestry and have considerable experience in forestry research.

Salary includes a substantial tax-free allowance paid under Britain's overseas aid programme. Basic salary attracts 25% tax-free gratuity.

Benefits include free passages, generous paid leave, children's holiday visit passages and education allowances, subsidised housing, appointment grant and interest-free car loan.

The terms on which civil and public servants may be released if selected for appointment will be subject to agreement with their present employers.

For full details and application form write quoting MD/129/NA or telephone 01-222 7730 ext 3603.

February 12, 1979. 9129(

Tropical Products Institute

Pharmacologist/Toxicologist

The scientist appointed to this London based post will carry out a variety of pharmacological, toxicological and nutritional studies on renewable tropical products, using *in vitro* and *in vivo* tests and short term feeding trials. The work will involve planning experiments, administering test materials to animals or tissue cultures, assessing the effects of the experiment, determining the statistical significance of results and writing reports on the findings. In addition, the successful candidate will train visiting overseas personnel and deputise for the head of the sub-section when necessary. Weekend work, attending to care of animals, is required on a rota basis.

Candidates, normally aged under 27, must have a Degree/HND/HNC or equivalent in an appropriate subject. Possession of a Home Office Licence for working with animals or the aptitude for obtaining one is essential. The appointment calls for an ability to work with the minimum of supervision.

Appointment as Scientific Officer (£3300-£4880) with starting salary according to qualifications and experience. Promotion prospects. Non-contributory pension scheme.

For further details and an application form (to be returned by 1 February 1979) write to Miss C. A. Hall, Tropical Products Institute, 127 Clerkenwell Road, London EC1R 5DB. *Please quote ref: SA/95/JD.*

Army Blood Supply Depot, Aldershot

Scientists: Haematology & Blood Transfusion Work

These posts offer an opportunity to experienced haematologists and blood transfusion scientists to join a team working on all aspects of blood banking and blood group serology.

The senior appointment involves responsibility for the day to day running of the blood processing Laboratory where ante-natal serology and antibody identification is undertaken; the external quality assurance programme for world wide laboratories and the internal quality control programme covering haematology, bio-chemistry, bacteriology, sterility and serology. In addition the successful candidate will participate in various training courses undertaken during the year. Appointment as Senior Scientific Officer (£5150-£6900) or Higher Scientific Officer (£4100-£5450) according to qualifications and experience.

There is a second post, at Scientific Officer level, concerned with the routine processing of donor bloods, ante-natal serology and identification of antibodies. The person appointed will also prepare and issue blood products, help with research projects and supervise the work of junior staff. Salary is in the range £2840-£4410 with starting salary according to qualifications and experience.

Candidates, normally aged under 32, should have a Degree/HND/HNC or equivalent in an appropriate scientific subject. Some experience in haematology and blood transfusion is essential; for the senior appointment at least 2 years' relevant postgraduate experience is required.

The successful candidates will be given every encouragement to study for a higher qualification. There are promotion prospects and a non-contributory pension scheme.

For further details and an application form (to be returned by 6th February 1979) write to Ministry of Defence, CM(S)1b3, Room 310, Savoy Hill House, Strand, London WC2R 0BX. *Please quote ref: SA/2/FYA.*

Applications are invited from engineers or physical scientists who wish to join a small interdisciplinary group working on the important problem of incontinence. The appointee would be expected to take a particular interest in models of the bladder and urethra and to apply this work to the design of artificial drainage systems for the management of incontinence. The appointment is for up to 3 years. Starting salary range p.a.: £3,883 to £4,882. Further information from Professor B. R. Pullan, Department of Medical Biophysics, Stopford Building, University of Manchester, Manchester M13 9PT. 9045(A)

ASSISTANT PROFESSOR

YALE UNIVERSITY

DEPARTMENT OF BIOLOGY

This Department invites applications for appointment beginning in academic year 1979–80 or 1980–81 as Assistant Professor from persons with interests in molecular aspects of Genetics or Development. The appointee will be expected to contribute to a strong program of research and scholarship in Molecular Biology, and to participate in undergraduate and graduate teaching.

Send curriculum vitae, resume of past and present research, and names of three referees to:

Chairman
Department of Biology
Yale University
New Haven, Conn. 06520

Yale University is an Equal Opportunity/Affirmative Action Employer.
9132(A)

Director General Nature Conservancy Council

The Council seek a Director General to succeed Mr R E Boote, CVO, who reaches retiring age in Spring 1980

The appointment is a statutory one under the Nature Conservancy Council Act, 1973, made by the Council with the approval of the Secretary of State for the Environment.

The Director General is responsible to Council for the direction and organisation of the NCC, for advice on the formulation of Council's policies and for their implementation, and has personal responsibilities for effective management and financial control as the Accounting Officer He is assisted by a Deputy Director General and Chief Scientist, and by Directors for England, Scotland and Wales, to whom there is considerable delegation.

The NCC is an Independent body set up under the 1973 Act It is the statutory adviser to Government on nature conservation in Great Britain and is involved with a wide range of interests at home and abroad

In particular, the NCC is responsible for 163 National Nature Reserves and has responsibilities in relation to nearly 4,000 Sites of Special Scientific Interest It commissions and undertakes research and makes grants to many voluntary bodies Its annual budget is around £7m. and it employs 650 full time staff, of whom half are scientists, land agents and wardens

The post is open to a person with a good knowledge and background in, for example, biological science, land use (such as agriculture or forestry), land management or other related disciplines together with an understanding and knowledge of environmental issues within the legislative, planning and educational framework The successful candidate must be able to demonstrate leadership in promoting nature conservation and liaising with a variety of organisations both governmental and voluntary and to operate both nationally and internationally in a wide range of public and professional forums. He or she must have the capacity and experience in management and administration to direct effectively an organisation operating throughout Great Britain using a variety of scientific, land management and administrative skills

The post is also open to candidates from within the Nature Conservancy Council and the Public Service

The salary at April 1, 1980 will be £16,000 per annum, plus London weighting The NCC has its own non-contributory pension scheme based on that of the Civil Service. The post is based at NCC's Great Britain Headquarters in London.

Applications giving career details, including present salary and responsibilities, with information of special relevance to the post, should be sent, envelope marked *DG Post* and *Personal*, to Professor F G T Holliday, CBE FRSE, Chairman, Nature Conservancy Council, 19/20 Belgrave Square, London SW1X 8PY by not later than Friday March 9, 1979. In the first instance two referees should be named. Interviews will take place in May and June 1979 and the successful candidate will be expected to take up post early in 1980

Microbiologists

Petrolite Ltd, a leading service company to the oil industry are offering an exciting opportunity for a fully qualified Microbiologist to join their Technical Services Team.

Although based in Liverpool the position will involve trouble-shooting travelling as necessary to the major oil-fields of the world in order to solve the problems caused by bacterial growth in oil-field and industrial waters Your priority will be to make full recommendations, based on practical work in the field, of specific bio-cides to be used.

To cope with the demands of this challenging position you will have Post Graduate experience in Microbiology of Corrosion plus the personal qualities of self-motivation, flexibility and initiative

An attractive salary according to experience will be negotiated with the successful candidate.

Professional
& Executive
Recruitment

Applications are welcome from both men and women.

Centre for Overseas Pest Research, London

Scientific Librarian

The Centre for Overseas Pest Research helps governments of overseas territories, in particular the less developed countries, to solve pest problems in the fields of pre-harvest agriculture and public health through the technical co-operation programme. The Centre also provides scientific information, advice and training in Britain and overseas.

This post is in the Library Service where the person appointed will take responsibility for periodical literature and exchange material, liaison with overseas and other organizations regarding exchange of publications, and the supervision of a part-time assistant. In addition the successful candidate will scan, procure, catalogue, classify and index world-wide scientific literature including foreign language material, maintain collections of trade literature on pesticide chemicals and pesticide application equipment, deal with readers' enquiries for staff and visitors and undertake additional duties, as and when required including interpretative work in the subject field.

Candidates, normally aged under 27, must have a good honours degree, preferably in a biological science or agriculture or closely related subject, coupled with postgraduate training/experience in librarianship. An aptitude for languages is desirable.

Appointment as Scientific Officer (£3300-£4880) with starting salary according to qualifications and experience. Non-contributory pension scheme.

For further details and an application form (to be returned by 5 February 1979) write to Miss M. Cole, Centre for Overseas Pest Research, College House, Wrights Lane, London W8 5SJ. *Please quote ref: SA/50/JA.*

9077(A)

Science Group
CIVIL SERVICE

Biometrician

The Forestry Commission offers a period appointment of 3 years, for a Biometrician to join a team in the Statistics on Computing Section at the Forest Research Station, Roslin near Edinburgh.

The successful candidate will be required to help in the organisation and provision of advice to other branches of Forest Research, to advise project leaders on design of experiments and surveys, analyse results and report clearly and program various computers using remote terminal or batch. There will also be opportunities to initiate and lead practical research.

Candidates should have a good honours degree or equivalent qualifications in Statistics or related subject, plus at least 4 years relevant experience and be in the age range of 25 to 30 years on the 31 December 1978. The successful candidate will be appointed to either the Higher Scientific Officer (£4,101—£5,448) or Senior Scientific Officer (£5,154—£6,898) grade according to age, experience and qualifications.

Application forms and further details may be obtained from Mr A J Freeman, Personnel Branch, Forestry Commission, 231 Corstorphine Road, Edinburgh, EH12 7AT. Completed application forms must be returned not later than 6th February 1979. 9069(A)

IMMUNOCHEMIST

Postdoctoral position is available immediately to work on anti-tumour resistance induced by bacterial products. Strong background in chemistry is essential. Research assistant position on the same project is also available immediately. Submit resume, three references and transcripts to Professor A. Nowotny, University of Pennsylvania, Building A2, 4010 Locust Street, Philadelphia, PA 19104.

9114(A)

MUSEUM DIRECTOR

The University of Colorado at Boulder invites applications and nominations for the Director of the University Museum. The Museum conducts regional, national, and international research and educational programmes in the fields of natural history including anthropology and interacts with related University academic departments. Candidates must excel in administration, leadership, and research (including curation); must have a Ph.D.; must be strongly committed to University and community service and education; and must be able to interact positively with University administration, related academic departments, professional organisations, and funding agencies. Applications consisting of Curriculum Vitae, five names of references with addresses, and summary of administrative and research experience should be sent to:

Dr Robert A. Bye, Jr.
Chairman,
Museum Director Search Committee,
Department of Environmental,
Population and Organismic Biology,
Box 334,
University of Colorado,
Boulder, Colorado 80309 U.S.A.

Deadline for applications: March 15, 1979.

Anticipated starting date: June 1979 (negotiable).

An Equal Opportunity/Affirmative Action Employer. 9116(A)

EUROPEAN MOLECULAR BIOLOGY LABORATORY

ELECTRON MICROSCOPY TECHNICIAN

The European Molecular Biology Laboratory at Heidelberg, F.R.G. requires an electron microscopy technician to work on central nervous tissue for a project investigating visual structures in insects. Proficiency in electronmicroscopy techniques and the operation of an electronmicroscope is essential. Previous work on central or peripheral nervous system would be desirable, but not essential. The post is available immediately.

Apply to Dr N. Strausfeld, EMBL, Postfach 10.2209, D6900 Heidelberg, telephone number 06221-387-295, citing ref. 79/2. 9118(A)

UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF BIOCHEMISTRY

A vacancy exists for a Research Fellow (Range IA) who must be a postdoctoral biochemist with experience of radiochemical techniques to work for three years with Dr D. E. Briggs on an S.R.C.-funded project on the mechanism(s) regulating gibberellin release from barley embryos. The salary will be in the range £4,382 to £4,882 per annum (plus U.S.S.). The successful applicant would be required to take up appointment in the period between May and October 1979.

Applications (two copies) including a curriculum vitae and names of two referees should be sent to Miss L. R. Heyes, Senate Registry, University of Birmingham, P.O. Box 363, Birmingham B15 2TT, from whom further particulars may be obtained. The closing date is February 2, 1979.

KING'S COLLEGE HOSPITA
MEDICAL SCHOOL

(University of London)
Denmark Hill
London SE5 8RX

LIVER UNIT

Applications are invited for th position of Research Assistant/Fello in this busy multi-disciplinary uni from candidates with experience i cell membrane biology, immuno chemistry or protein biochemistry, t work on human liver cell surfac antigens.

Salary will be on University o London scales, according to qualifica tions and experience.

Please apply, giving full curriculu vitae and the names and addresses o two referees to the Secretary of th Medical School at the above address from whom further details may b obtained. Closing date February 1979. 9074(A)

ROYAL POSTGRADUATE MEDICAL SCHOOL

DEPARTMENT OF ANAESTHETICS

TECHNICIAN

with H.N.C. or similar qualificatio required for this very active researc department. The person appointed wil be expected to be capable of assumin responsibility for cardio-respirator and blood gas measurements. Experi ence in gas chromatography, physic logical measurement or electronics i desirable. Starting salary within th range £4,009 to £4,854 depending o experience and qualifications, goo holidays and contributory superannu ation scheme.

Application forms may be obtaine from the Personnel Office, Royal Pos graduate Medical School, 150 Du Can Road, London W12 0HS quotin reference number 14/104/ .

9073(A)

CHELSEA COLLEGE

University of London

BASIC MEDICAL SCIENCES GROUP

Applications are invited for the posts of:—

1. POSTDOCTORAL RESEARCH ASSISTANT

(salary £4,583 to £5,081, inclusive of London Allowance

2. RESEARCH TECHNICIA GRADE 5

(salary £3,651 to £3,858, inclusive of London Allowance

to work on a three-year M.R. funded project concerned with th application and production of mon clonal antibodies to cytoskeletal pr teins from nervous tissue, in pa ticular, neurofilaments. Experience i protein chemistry, or tissue culture o immunology would be desirable.

Further particulars and applicatio with curriculum vitae to Dr B. Anderton, Basic Medical Scienc Group, Chelsea College, Manres Road, LONDON SW3 6LX.

9072(A)

POSTDOCTORAL POSITIO

of 2-year duration

available immediately for sequence a affinity labelling studies on ribulosebi phosphate carboxylase at salary $12,000 for first year. Please se resume and letters of references t Dr Fred C. Hartman, Oak Ridg University of Tennessee Gradua School of Biomedical Sciences, P. Box Y, Oak Ridge, TN 37830. *Equal Opportunity/Affirmative Acti Employer.* 9085(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited for

TWO LECTURESHIPS

in the

DEPARTMENT OF PURE AND APPLIED CHEMISTRY

Applicants for one of the posts should be experienced in (experimental) INORGANIC CHEMISTRY and for the other in CHEMICAL TECHNOLOGY.

Salary scale £3,883 to £7,754 with placing according to qualifications and experience. Superannuation benefit.

Application forms and further particulars (quoting 1/79 for the Lectureship in Inorganic Chemistry and 2/79 for the Lectureship in Chemical Technology), and enclosing a self-addressed envelope (9"×4"), may be obtained from the Academic Appointments Officer, University of Strathclyde, Royal College Building, 204 George Street, Glasgow G1 1XW, with whom applications should be lodged by February 26, 1979.

9059(A)

UNIVERSITY COLLEGE OF NORTH WALES

BIOCHEMISTRY

Applications are invited for the post of

PROFESSOR

of Biochemistry and Head of Department

The appointment will be from OCTOBER 1, 1979 (or a date to be arranged) and the salary will be in the professorial range.

Further particulars can be obtained from the Secretary and Registrar, University College of North Wales, Bangor, Gwynedd LL57 2DG.

Ten copies of the application (one from overseas candidates) together with the name of three referees should be sent to reach the Secretary and Registrar by Friday, February 16, 1979.

9048(A)

ISRAEL INSTITUTE OF TECHNOLOGY, HAIFA RESEARCH ASSOCIATE POSITION

available for a period of two or three years.

Experimental background in Chemical Physics, Electrochemistry and/or Surface Science required.

Contact Prof D. S. Tannhauser, Department of Physics. 9051(A)

UNIVERSITY OF CAPE TOWN

SENIOR LECTURESHIP IN INORGANIC CHEMISTRY

Applications are invited for the above post, vacant as from July 1, 1979. Appointment, according to qualifications and experience, will be made on the salary scale R8,460 by R360 to R9,900 by R450 to R11,250 per annum, plus a pensionable allowance of 19.9 per cent of basic salary.

Applicants should submit a curriculum vitae, stating present salary, research interests and publications, the date duty could be assumed, and the names and addresses of three referees.

Memoranda concerning the position and general conditions of service should be obtained from the Registrar, Room 10, University of Cape Town, Private Bag, Rondebosch 7700, South Africa, by whom applications must be received not later than April 30, 1979.

Appointment will be subject to a satisfactory medical examination.

The University's policy is not to discriminate in the appointment of staff or the selection of students on the grounds of sex, race, religion or colour. Further information on the implementation of this policy is obtainable from the Registrar.

9094(A)

The Daresbury Laboratory has vacancies for

THEORETICIANS

in all three fields of interest of the Theory Group at Daresbury which are solid state, atomic and molecular, and nuclear.

At the laboratory a purpose-built X-ray and ultra-violet source and a major nuclear structure facility based on a 30 MV tandem Van de Graaff are under construction. An IBM 370/165 computer is installed at the laboratory, and a computational science group has recently been established working mainly in the quantum chemistry area.

Appointments will be made at salaries between £3695 and £6216, the level at which an associate is appointed depending on age, ability and experience. Posts are normally available for a fixed term of 3 years and are superannuable.

The successful applicants will be expected to take a strong interest in the experiments which are being planned on the new facilities.

Applicants, of either sex, should possess a Ph.D. degree in the relevant area, or expect to obtain one during 1979.

Closing date: 14 February 1979.

For further information please write or telephone the head of the theory group, Dr. J. B. Pendry (Tel. No. (0925) 65000 Extension 223). Applications should be sent together with curriculum vitae and the addresses of two referees, quoting reference number DL/650/9070(A) to:

The Personnel Officer

DARESBURY LABORATORY
Science Research Council
Daresbury, Warrington WA4 4AD

9070(A)

KENYATTA UNIVERSITY COLLEGE—KENYA

(a constituent college of the University of Nairobi)

Applications are invited for

LECTURESHIPS IN THE PHYSICS DEPARTMENT

Applicants should be holders of a Ph.D. Appointees will join the staff of Physics Department offering courses to degree level to future Secondary School teachers together with an M.Sc. Physics programme. The department has special interests in teaching and in the field of Appropriate Technology and Electronics Applications. Any speciality will be considered.

Salary scale: K£2,016 to K£3,312 p.a. (K£1=£1.34 sterling.) The British Government may supplement salary in range £4,278 to £4,818 p.a. (sterling) for married appointee or £2,730 to £3,156 p.a. (sterling) for single appointee (reviewed annually and normally free of all tax) and provide children's education allowances and holiday visit passages. Family passages; subsidised housing; S.S.S.F. or F.S.S.U.; non-contributory medical aid scheme.

Detailed applications (2 copies) with curriculum vitae and naming 3 referees to be sent direct to the Registrar, Kenyatta University College, P.O. Box 43844, Nairobi, Kenya, by February 2, 1979. Applicants resident in the U.K. should also send one copy to Inter-University Council, 90/91 Tottenham Court Road, London W1P 0DT. Further details may be obtained from either address. 9122(A)

SOUTH GLAMORGAN HEALTH AUTHORITY (T)

CARDIFF ROYAL INFIRMARY

SUPRA-REGIONAL PROTEIN REFERENCE UNIT

Applications are invited for the post of

RESEARCH ASSISTANT

to work on the development and assessment of immune complex assays in clinical chemistry. This project is supported by the Welsh Office scheme for the development of Health and Social Research. The post will be for **one year** in the first instance but renewal for the second year may be possible.

Candidates should have a degree in Biochemistry, Biological Sciences or equivalent and salary scales will be according to qualification and experience, but will be on the Whitley Scale for probationary grade Hospital Biochemists.

Further details of the project and the post can be obtained from—Dr R. Fifield, Protein Reference Unit, Cardiff Royal Infirmary, telephone 0222 492233, ext. 559.

Application forms can be obtained from Assistant Unit Administrator, Cardiff Royal Infirmary. Tel: Cardiff 492233.

Closing Date: January 26, 1979. 9081(A)

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Applications are invited for the post of Technician who will work on a study of trace element metabolism in preterm infants. The job involves work in the laboratory and in the Premature Baby Unit. Familiarity with atomic absorption spectrophotometry desirable but not essential. Please submit Curriculum Vitae and the names and telephone numbers of two referees to the Secretary, University College Hospital Medical School, University Street, London WC1E 6JJ, quoting reference T/JS. 9075(A)

SURFACE PHYSICIST/ CHEMIST

Fusion energy research on plasma-wall interaction phenomenon involving atomic hydrogen chemical sputtering and surface cleaning. Uhv and surface physics/chemistry experience appropriate. Appoint at Research Associate or Senior Research Associate level. Appointment for three years initially. Well-qualified scientist sought. Appropriate salary available.

Write: Professor P. C. Stangeby, University of Toronto, Institute for Aerospace Studies, 4925 Dufferin Street, Downsview, Ontario M3H 5T6. (416) 667-7729. 9083(A)

CHEMICAL ENGINEERING RESEARCH GROUP—CSIR

Would you like an opportunity to apply your professional skills in depth to the solution of problems of an applied or fundamental nature in a stimulating interdisciplinary environment?

The Chemical Engineering Research Group—CSIR is one of over a dozen institutes of the Council for Scientific and Industrial Research. The Group is engaged in R & D and consulting services related to the utilisation of the natural resources of the country and the development of its process industry. We have openings for

SENIOR RESEARCH STAFF and temporary RESEARCH FELLOWS

PARTICLE TECHNOLOGY — FLUID DYNAMICS

Solid-fuel separation and suspension flow in process equipment requiring the application of engineering science in the processing of particulate matter.

RHEOLOGY

Investigations of the rheological properties of materials used in the process industry, particularly suspensions of particles.

HETEROGENEOUS CATALYSIS

The development of catalysts and catalytic processes for the conversion of coal and oil to liquid fuels and petrochemicals, including the downstream processing of the intermediates.

COMBINED HEAT AND MASS TRANSFER

The development of techniques to determine optimal drying procedures and the consequent selection of drying equipment for industry.

ELECTROSTATIC PRECIPITATION

Investigations leading to improvements in the control of emissions from power stations.

General requirements: a PhD or at least an advanced degree in a relevant discipline, research ability, experience in the indicated field and the ability to communicate research results.

SOME POSTS AT GRADUATE LEVEL ARE ALSO AVAILABLE

Pursuit of an advanced degree is encouraged and financially supported.

Conditions of service: Attractive remuneration, a pleasant climate and working environment on a large campus where most of the CSIR institutes are housed, scope for initiative, advance on merit, generous leave allocation, substantial housing subsidy, holiday bonus, pension and medical aid schemes, group life insurance and other fringe benefits, outstanding laboratory, workshop computing and information facilities, relocation expenses.

Apply to: The Head, CERG—CSIR, P.O. Box 395, PRETORIA, 0001 South Africa 9060(A)

Lecturer Grade II/ Senior Lecturer in Physiology

(£4101 - £7065 (Bar) - £7572)

Candidates should preferably have experience in Histology, Electron Microscopy, exercise physiology or sports science.

Further details and form of application available from The Assistant Director and Chief Administrative Officer, Trent Polytechnic, Burton Street, Nottingham. A self-addressed foolscap envelope will assist in the speedy despatch of documents.

Applications to be returned as soon as possible.

9102(A)

TRENT
POLYTECHNIC
NOTTINGHAM

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

Applications are invited for chemists or chemical physicists for an S.R.C. Postdoctoral Senior Research Assistantship for 17 months from as soon as possible to work in collaboraton with Dr J. Yarwood on the interaction and dynamics of hydrogen bonded systems in the liquid phase. These studies which include infrared, far-infrared, Raman and neutron scattering studies are also supported by a N.A.T.O. research grant and would be carried out at Durham, the Technical University, Braunschweig and at A.E.R.E. Harwell. Some experience in one branch of molecular spectroscopy is essential and an interest in the chemical physics of molecular motions and interactions in the liquid phase would be an advantage.

Initial salary £3,883 or £4,133 per annum on National Research Range 1A plus superannuation.

Applications (three copies) naming three academic referees should be sent by January 22, 1979, to the Registrar and Secretary, Science Laboratories, South Road, Durham DH1 3LE.

8904(A)

UNIVERSITY OF DUBLIN
Trinity College

LECTURER IN GEOLOGY

Applications are invited for the above post in the Department of Geology, Trinity College, Dublin, from candidates with strong academic qualifications and with substantial interest in developing courses in applied aspects of the geological sciences, such as environmental geology and engineering geology.

Salary Scale: £4,232 to £8,321. Appointment will be made within the range £4,232 to £4,680. There is a non-contributory pension scheme.

Application forms and further particulars may be obtained from:

The Establishment Officer
West Theatre
Trinity College
Dublin 2

to whom completed applications should be returned not later than January 31, 1979. 9066(A)

DISTINGUISHED ENERGY PROFESSORSHIP AT SYRACUSE UNIVERSITY

Nominations and applications are invited for the Niagara Mohawk Energy Chair at Syracuse University. The holder of the Chair must be a recognised scholar and is expected to provide leadership in the establishment of an interdisciplinary centre of excellence for energy research and in the development of energy curricula. The candidate should have experience in high-efficiency, bulk-energy conversion techniques using environmentally acceptable processes for the utilisation of coal or nuclear fuels. The Chair is expected to be attached to the Department of Chemical Engineering and Materials Science which has a particular interest in fluidised bed technology. Outstanding scholars in other energy-related areas are also eligible. Nominations and applications should be sent to Professor David K. Cheng, Chairman, Energy Professor Search Committee, Link Hall, Syracuse University, Syracuse, N.Y. 13210, before April 1, 1979. Syracuse University is an equal opportunity affirmative action employer. 9115(A)

ANIMAL HOUSE TECHNICIAN

(Readvertisement)

Applications are invited for the pos of Technician in the School of Biological Sciences to take responsibilit for the running of an Animal Uni housing small mammals, insects an amphibia.

Candidates must have had severa years experience of Animal Hous work and hold qualifications of th Institute of Animal Technicians.

Salary on the scale £3,186 to £3,72 (under review).

Further particulars and applicatio forms may be obtained from th Superintendent of Laboratories, Schoo of Biological Sciences, University o East Anglia, Norwich NR4 7TJ, t whom they should be returned withi two weeks of the publication of thi advertisement. 9134(A)

POSTDOCTORAL POSITION

Ph.D. of M.D. with good background in membrane biochemistry fo studies of composition and structur of nexuses (gap junctions). Laborator is well equipped for membrane bio chemistry and ultrastructure (includin freeze-fracture, rapid freezing, lase diffraction etc.). Starting date, Marc 1, 1979. Send resume and two letter of recommendation to: Camill Peracchia, Department of Physiolog University of Rochester, School o Medicine, 601 Elmwood Avenue, Bo 642, Rochester, New York 1464 Affirmative action/equal opportunit employer. 9113(A)

POSTDOCTORAL POSITION

Three-year position available immediately for research on the control of insect reproductive development. Recent Ph.D. (biochemistry, developmental biology, or insect physiology) with experience in nucleic acid chemistry preferred.

Send curriculum vitae and references to:

Dr George M. Happ,
Department of Zoology,
University of Vermont,
Burlington, VT 05405.

An Affirmative Action Employer.
9136(A)

UNIVERSITY OF EXETER

DEPARTMENT OF BIOLOGICAL SCIENCES

RESEARCH ASSISTANT

Applications are invited for a graduate research assistant, to be based in either Exeter or Bath, to work with Drs Todd and Rayner on an S R C.-funded project "Intraspecific Antagonism in Natural Populations of Wood-Decaying Fungi". The genetics, biochemistry and structural changes associated with this phenomenon and its biological and pathological implications will be studied. Preference will be given to applicants with experience in any of these areas. The successful applicant may be permitted to register for a higher degree.

The appointment is for one year in the first instance, starting as soon as possible, with the possibility of renewal for a further two years. The commencing salary will be £3,384 p.a. (£3,634 for the second year and £3,883 for the third year).

Applications, together with a curriculum vitae, giving details of age, qualifications and experience, and the names of two referees should be sent by February 1, 1979, to Dr N. K Todd, Washington Singer Laboratories, University of Exeter, Exeter EX4 4PS
9049((A)

FOOD ENGINEERING

Applications are invited for a

PROFESSORIAL POSITION

in the Department of Chemical Engineering and Applied Chemistry, University of Toronto. The opening relates directly to an expansion of teaching and research in the field of food engineering. The expansion is possible as a result of a Development Grant from the Connaught Committee, University of Toronto. The appointment is in the tenure stream, commencing July 1, 1979. Applicants should possess a Ph.D or its equivalent in chemistry or chemical engineering, and have a demonstrated or potential ability to teach at the postgraduate level and to initiate research. It is expected that the appointment will be made in either the Assistant or Associate Professor rank.

Applications with curriculum vitae and the names of three referees should be sent to:

Professor M. E. Charles,
Chairman, Department of Chemical Engineering and Applied Chemistry
University of Toronto
Toronto, Ontario
Canada M5S 1A4.
9052(A)

PROFESSOR OF PHYSIOLOGICAL OPTICS

The College of Optometry at The Ohio State University with its graduate programme in physiological optics, has an opening at the full professor level for a vision scientist of outstanding calibre. The candidate must be an effective teacher and an active and recognised researcher. A Ph.D (or equivalent) degree is required. Selection and salary depend on ongoing productivity, relevance to this programme's needs, and potential for continuing development.

Send curriculum vitae, bibliography, and three references to: Chairman, Search Committee, The Ohio State University, College of Optometry, 338 West 10th Avenue, Columbus, Ohio 43210, (614) 422-2647 (The Ohio State University is an affirmative action equal opportunity employer.)
9111(A)

GUY'S HOSPITAL MEDICAL SCHOOL
(University of London)

POSTDOCTORAL RESEARCH ASSISTANT

required to join a research group under Dr L. Mallucci in the Department of Microbiology investigating the role of cell surface membrane components in cell growth regulation and cell differentiation. Position available to December 1979 with the possibility of further renewal of grant.

Salary in range £3,910 to £5,506 plus £450 London Allowance and superannuation.

For further details telephone Dr Mallucci.

Applications to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT.
9055(A)

MEMORIAL UNIVERSITY OF NEWFOUNDLAND

FACULTY OF MEDICINE

ASSISTANT PROFESSOR OF IMMUNOLOGY

Immunologist/Immunogeneticist required at Assistant Professor (and Postdoctoral fellow) level to join others in a medical school immunology group. Special research strengths of this group are a good HLA lab (International workshop standard), complement allotyping, collaborative relationships with the blood bank, biochemical genetics, cytogenetics and with clinical investigators, plus the availability of large families. Our group is also involved in teaching, in a clinical immunology diagnostic laboratory and with a transplantation programme.

For more information please write, preferably sending detailed curriculum vitae plus any relevant reprints, to Dr W. H Marshall, Professor of Immunology, Faculty of Medicine, Memorial University of Newfoundland, Canada, A1B 3V6.
9137(A)

UNIVERSITY OF MELBOURNE

Australia

LECTURESHIP

(Limited Tenure)

in the School of Physics

Applications are invited for a Lectureship (Limited Tenure) in the School of Physics. The current research interests of the School are high energy physics, diffraction physics, low energy nuclear physics and theoretical physics.

The successful applicant will be required to teach at an undergraduate level by lecturing or supervising laboratory classes, to supervise research students and to conduct research in one of the above-mentioned areas of physics.

Qualifications: Ph.D. with postdoctoral experience.

Salary: $A15,179 to $A19,940 per annum.

The position may be taken up from September 1979.

Further information, including details of application procedure and conditions of appointment, is available from the Registrar, University of Melbourne, Parkville, Victoria, 3052, Australia, or the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF. Applications close on February 28, 1979.
9124(A)

RESEARCH GRADUATE

to undertake studies in relation to human myeloma cultures and their influences on antibody formation etc. Prior experience of tissue culture, lymphocyte culture or bone marrow work is preferred. Excellent opportunity for a Ph D thesis. Salary Whitley Scale A according to experience. Applications, with two referees, to Professor J. R Hobbs, Westminster Hospital, Department of Chemical Pathology, 17 Page Street, London SW1P 2AR, by January 28, 1979.
9110(A)

ROYAL OBSERVATORY, EDINBURGH

SENIOR APPOINTMENT

There is a vacancy for someone with a proven record of success in the management of projects with a considerable technological content to join the Observatory's senior management team.

The Observatory is responsible for three national facilities which support University research: the Image and Data Processing Unit which includes the advanced measuring machine COSMOS; the 3.8 m aperture Infrared Telescope currently being erected in Hawaii, and the UK 1.2 m aperture Schmidt Telescope in Australia. The last two also have associated laboratories at Edinburgh and all three, together with the in-house research, are supported by Technology and Administration Groups. All major activities in the Observatory are managed by senior research scientists who are expected to spend on average half of their time on research. Management duties sometimes involve overseas postings, currently to Australia or Hawaii, for periods of about three years.

The successful candidate for this post will in the first instance be made responsible for overall management of the Technology Group.

Applicants should detail their project management and research experience which should preferably be in the fields of astronomy or instrument development and/or precision engineering.

Salary, depending on qualifications and experience, on the scale £10,043—£11,300 per annum.

SRC

Letters of application, including a full curriculum vitae, should be sent to Mr B McInnes, Royal Observatory, Blackford Hill, Edinburgh (Tel No 031-667 3321) by 31st January 1979.
9056(A)

ORPINGTON HOSPITAL SECTOR

DOMESTIC SUPERVISOR

male or female required for the above Sector, which includes responsibility for the Angus Home, Cudham, a residential home for 28 female adult mentally handicapped residents. The successful applicants will join our team of supervisors responsible for the Domestic Staff in the Sector.

Previous experience preferable. 40-hour week working from 7.30 a m to 4 p.m. Monday to Friday. Weekly earnings £53.54.

Application form from:
Sector Administrator,
Orpington Hospital,
Orpington, Kent, BR6 9JU.
(Tel. Orpington 27050, ext 86.)
9141(A)

SIR WILLIAM DUNN SCHOOL OF PATHOLOGY

RESEARCH ASSISTANT

(Grade 1A—
Salary £3,383 to £6,555)

Applications are invited for a Research Assistant, supported by the Cancer Research Campaign, to assist with research into the biochemical mechanisms of virus growth. Experience with mammalian tissue culture would be an advantage. Applicants should possess a degree or equivalent qualification.

Applications, in writing, together with the names and addresses of two referees, to the Administrator, Sir William Dunn School of Pathology, South Parks Road, Oxford OX1 3RE.
8960(A)

ST HELIER HOSPITAL

Wrythe Lane
Carshalton, Surrey

RESEARCH ASSISTANT

with working experience in immunology in Dermatology Department.

An original enthusiast needed who will help to investigate several aspects of Dermatology including malignancy.

Laboratory staff will consist of two full-time Biochemists, Senior Registrar and Consultant.

Salary according to experience. Post reviewed annually.

Applications to Dr E. Rhodes at above address. Closing date: February 9, 1979
9096(A)

THE BREWING RESEARCH FOUNDATION

require a

MOLECULAR BIOLOGIST/ YEAST GENETICIST

Applications are invited from persons interested in developing recombinant DNA techniques for the genetic improvement of commercially important strains of yeast. Candidates should have (or expect to obtain shortly) a Ph.D in an appropriate area of biochemistry, molecular biology or genetics. Experience in the use of restriction enzyme/DNA cloning methodology would be preferred. Appointment will be to the scientific staff of the Foundation at an appropriate point on the Scientist scale (£4,486 to £6,200). Applications, including curriculum vitae and names of two referees should be sent to: The Administrative Manager, Brewing Research Foundation, Lyttel Hall, Nutfield, REDHILL, Surrey RH1 4HY.
9108(A)

Pharmacokineticist

May & Baker Ltd., is an international Company, manufacturing and marketing a wide range of research based chemical products.

Following a functional reorganisation, we have a vacancy in the Department of Drug Metabolism at our Research Institute at Dagenham, Essex, for a graduate with pharmacokinetic experience.

The successful applicant will lead a small team working on the design, implementation and competent reporting of pharmacokinetic and bioavailability studies. A good knowledge of analytical apparatus and its application is essential and a general knowledge of drug metabolism is desirable.

Benefits of employment include flexible working hours, bonus scheme and contributory pension scheme. Publication of appropriate work is encouraged and the Department has active links with a number of University and Clinical Pharmacokinetic Departments throughout the world.

Please telephone 01-592 3060 extension 2506 for an application form or write with full details of age, experience, qualifications and present salary to Mrs. Phyllis Clark, Personnel Officer (Scientific Staff),

Director

PHLS Centre for Applied Microbiology & Research, Porton Down

The PHLS Centre for Applied Microbiology and Research will take over and develop the civil and health oriented aspects of the work of the Ministry of Defence Microbiological Research Establishment at Porton Down, Wiltshire, on April 1, 1979 Within the Centre there will be reference laboratories for 'special' pathogens and laboratory safety, research laboratories concerned with microbial pathogenicity and vaccines, and laboratories involved in work on microbial products used in therapy, diagnosis and research.

The PHLS Board invites applications for the post of **Director of the Centre.** Candidates (male/female) should have an established research reputation in microbiology or some related aspect of public health, and experience in the management of a laboratory or similar department. While preference will be given to candidates with a medical qualification, applications from non-medical graduates with specially relevant interests or experience will be welcomed.

The duties of the post will include the promotion and co-ordination of the research activities of the laboratories within the Centre, and the integration of these activities with those of the PHLS and the health services generally

The appointment will be under PHLS (NHS) terms and conditions of service Further details of the post and salary scale may be obtained from **The Secretary, Public Health Laboratory Service Board, 61 Colindale Avenue, London NW9 5EQ,** to whom applications, stating date of birth, qualifications, experience, published work, and naming three referees, should be sent by February 12, 1979 The Director of the PHLS, Sir Robert Williams, will be pleased to discuss the post and to make arrangements for those interested in the post to visit the laboratories at Porton 9128(A)

PHLS Public Health Laboratory Service Board.

ROYAL HOLLOWAY COLLEGE
University of London
DEPARTMENT OF ZOOLOGY

N.E.R.C. RESEARCH ASSISTANT

required to work for two years with Dr J W. Lewis on the epidemiology of parasitic infections in small mammals. Post suitable for graduate in zoology/biology with a background in parasitology/mammalogy.

Salary on scale £3,410 to £3,659 plus London Allowance of £450. Starting date to be arranged.

Apply in writing, with curriculum vitae, to the Personnel Officer, Royal Holloway College, Egham Hill, Egham, Surrey. 9109(A)

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)

RESEARCH TECHNICIAN

Applications are invited for the post of Research Technician in the Metabolic and Endocrine Unit. The post includes work on problems of hepatic and acid base metabolism and also general laboratory duties. The appointment is for a maximum of three years and is supported by the Medical Research Council.

Initial salary £3,261 to £3,582, according to experience, plus £354 London Weighting.

Further details may be obtained from Professor R D. Cohen, Metabolic and Endocrine Unit, Tel: 01-247 5454, ext 412. Applications, together with the names of two referees, should be sent to the Secretary, The London Hospital Medical College, Turner Street, London E1 2AD, within 14 days, quoting reference RTMEU/1/79 9133(A)

THE KENNEDY INSTITUTE OF RHEUMATOLOGY

A postdoctoral or postgraduate

RESEARCH ASSISTANT

is required in the Division of Biochemistry to be involved in projects using culture techniques to investigate the cellular mechanisms involved in the control, development and repair of connective tissue Candidates should have a keen aptitude for research and previous experience of cell culture techniques. The appointment is funded by the Medical Research Council until November 1980

Salary £3,500 to £4,500 depending on age and qualifications.

Applications in writing giving full particulars of experience and qualifications and two referees to The General Secretary, The Mathilda and Terence Kennedy Institute of Rheumatology, Bute Gardens, Hammersmith W6 7DW. 9064(A)

AYRSHIRE AND ARRAN HEALTH BOARD, North Ayrshire and Arran District **SENIOR CYTOGENETICIST** (Science Graduate) required for Ayrshire Area Laboratory to work in a developing diagnostic service for the detection of human chromosome aberrations. Appropriate qualifications and experience in cytogenetics and cell culture are essential. The post will initially be based at Ballochmyle Hospital but will move to the new North Ayrshire District General Hospital in 1979 Further details may be obtained from the Pathology Department, Ballochmyle Hospital (Catrine 182, ext. 23). Applications with full details of qualifications and experience and names of two referees, to the North Ayrshire District Medical Officer, 1 Hill Street, Kilmarnock. 9135(A)

PLANT PHYSIOLOGIST/ BIOCHEMIST

The Agricultural Science Service of ADAS provides farmers and growers with a wide range of vital technical information and advice which is supported by investigational and development work carried out from regional centres across the country.

The officer appointed to this Wolverhampton based post will provide specialist advice to colleagues on physiological and biochemical problems in crop production, and to this end will maintain a close liaison with research workers in Institutes, Universities and Commercial Organisations In addition, the plant physiologist will initiate investigational work, develop and evaluate physiological techniques for use both in the field and the laboratory, and take responsibility for the day-to-day management of some laboratory and field staff.

Candidates (normally aged under 35) must have a Degree or equivalent in plant physiology or biochemistry and at least 3 years' relevant postgraduate experience.

Salary, starting between £4,175 and £5,770, rises to £6,890. There are promotion prospects and a non-contributory pension scheme.

For further details and an application form (to be returned by 2nd February 1979) write to Civil Service Commission, Alencon Link, Basingstoke, Hants, RG21 1JB, or telephone Basingstoke (0256) 68551 (answering service operates outside office hours). **Please quote ref: S(A)906.**

9104(A)

UNIVERSITY OF STRATHCLYDE

Applications are invited for a post of

RESEARCH ASSISTANT

in the DEPARTMENT OF ARCHITECTURE AND BUILDING SCIENCE to work on heat transfer processes in air-heating solar collectors.

Applicants should be graduates in either physics, mechanical, or environmental, engineering or have a background of practical experience in convective heat transfer work.

Appointment, which is for two years commencing March 1979, would be on Range IB of the national salary scale for research and analogous staff. Commencing salary will be on the scale £3,384 to £3,883 with placing according to qualifications and experience. Superannuation benefit.

Written applications (quoting R2/79) giving the names and addresses of two referees and stating full details of qualifications and experience should be sent to Dr P. P. Yaneske, Department of Architecture and Building Science, Architecture Building, 131 Rottenrow, Glasgow G4 0NG, from whom further information can be obtained. 9082(A)

VOM, NIGERIA
PROJECT DIRECTOR

A project director is required for the newly established Programme on the Biological Control of Tsetse Flies by the Sterile Insect Technique. The position will have overall administrative and technical responsibility, involving the various aspects of the project including production, ecology, and research.

The director should be an entomologist or veterinarian with experience in the Sterile Insect Technique, tsetse control, or ecology or trypanosomiasis.

The preferred date of appointment is April 1979 but a later starting date can be negotiated. Salary will be dependent upon qualifications. Applicants should send curriculum vitae and names of three references to:

Director, Joint FAO/IAEA Division
International Atomic Energy Agency
P.O.B. 590
A-1010 VIENNA, AUSTRIA.

9091(A)

HAREFIELD HOSPITAL
Harefield, Middlesex
DEPARTMENT OF CARDIO-THORACIC SURGERY
Research NUTRITIONIST/ BIOCHEMIST

required for one year.

An interesting vacancy exists for a Research Assistant to work on nutritional/biochemical problems to patients undergoing thoracic surgery. Applicants should preferably be graduates in biochemistry/nutrition. Salary scale: £3,798 to £4,899 plus London Weighting of £354.

Job description and application forms available from Miss P. Durand, Personnel Officer, Harefield 3737, ext. 528. Closing date: 14 days from appearance of advertisement. 9100(A)

QUEEN MARY COLLEGE
University of London
PLANT BIOLOGY AND MICROBIOLOGY DEPARTMENT

Applications are invited for appointment as

GRADUATE RESEARCH ASSISTANT

o work with Dr B. Frankland on an S.R.C.-supported project on phyto-hrome intermediates and induction of germination by irradiation of partially hydrated seeds. Post tenable for up to hree years from April, or as soon as possible thereafter.

Applications from those graduating n summer 1979 will be considered. Initial salary (under review) £3,834 p.a. including London Allowance).

Please apply by letter, giving age, qualifications and names of 2 referees, to The Registrar (N), Queen Mary College, Mile End Road, London E1 NS. 9140(A)

EAST BIRMINGHAM HEALTH DISTRICT
East Birmingham Hospital

A vacancy will exist from January 1, 1979 in the grade of

SENIOR MICROBIOLOGIST

The post is funded by the Medical Research Council as part of a Programme Grant for research into gastro-enteritis viruses, especially rotaviruses. Applicants should have a Ph.D. or equivalent qualification. The research programme is directed: (1) towards propagation of human rotaviruses in tissue culture, (2) determination of rotavirus serotypes and their distribution worldwide. This programme is closely linked with fundamental work on molecular biology of rotaviruses being carried out in the University of Warwick under Dr Malcolm McCrae.

Further particulars may be obtained from Dr T. H. Flewett, Regional Virus Laboratory, East Birmingham Hospital, Birmingham B9 5ST, or telephone Mr J. R. Foster, Senior Chief Medical Laboratory Scientific Officer, on 021-772 4311, Ext. 4086 for further details. 9098(A)

ST. MARY'S HOSPITAL MEDICAL SCHOOL
(University of London)
Paddington, London W2 1PG
GRADUATE IN PHYSIOLOGY OR PHARMACOLOGY

who will be expected to register for a higher degree, required to join team investigating the mechanism of action to drugs affecting gastric secretion.

Appointment, which can be taken up immediately, is for one year initially with prospect of extension for further two years. Project jointly organised between Departments of Physiology and Academic Surgical Unit.

Further information from Mr S. Knight (Tel: (01)-723 1252, ext. 133, to whom application with curriculum vitae may be sent at above address. 9126(A)

PALEOSERVICES LIMITED OF WATFORD

require a

PALYNOLOGIST

with Mesozoic and/or Paleozoic experience to undertake studies of Well sequences and basin analyses.

Salary nogotiable.

Please apply in writing to: Paleoservices Limited, Unit 2, Polychrome Building, Sandown Road, Watford, Herts WD2 4UB. 9093(A)

ASSISTANT PROFESSOR OF ANALYTICAL CHEMISTRY

—tenure track, fall 1979. Send curriculum vitae with a 250-word outline of your research interests, and request 3 letters of recommendation, to Dr D. H. Freeman (Chairman, Search Committee), Department of Chemistry, University of Maryland, College Park, MD 20742 U.S.A. E.O./A.A.E. 8968(A)

STUDENTSHIPS

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY

Applications are invited for a C.A.S.E. research studentship to work on the control of aerobic energy conservation in bacteria during growth in continuous culture. The project will be supervised by Dr C. W. Jones (University of Leicester) and Dr J. Linton (Shell Research Ltd, Sittingbourne). The studentship is tenable from October 1979 and the successful candidate will be expected to read for a higher degree. Applicants should possess, or expect to obtain, a good honours degree in Biochemistry or Microbiology and should write to Dr C. W. Jones, Department of Biochemistry, University of Leicester, Leicester LE1 7RH enclosing a curriculum vitae and the names of two referees. 9101(E)

AGRICULTURAL RESEARCH COUNCIL
Institute of Animal Physiology
Babraham, Cambridge CB2 4AT
RESEARCH STUDENTSHIPS

Applications are invited from recent graduates in Medicine, Veterinary Medicine, or holding a first or upper second class honours degree in Science, and from students expecting to graduate this year, for ARC/MRC Studentships for Training in Research Methods. The following research projects are offered:

1. Effect of stress on glucose metabolism in lactation;
2. Behavioural effects of electrical stimulation of the brain;
3. Nutrition and neuronal development;
4. Protein digestion in ruminants;
5. Protein metabolism in pregnancy and lactation;
6. Hormonal control of gene expression in target tissues;
7. Lymphocyte antigens and histocompatibility studies in sheep.

Successful candidates will be encouraged to apply for admission to Cambridge University as registered research students.

Applications giving birth date, nationality, full details of School and University record and the project favoured, with names of two academic referees should be sent to the Director, Dr B. A. Cross, FRS, by February 28, 1979. 9127(F)

COURSES

THE MEDICAL COLLEGE OF ST. BARTHOLOMEW'S HOSPITAL
(University of London)
RADIATION PHYSICS IN MEDICINE

Application are invited for the

JOINT M.Sc. COURSE IN RADIATION PHYSICS

which extends over one year for full-time students, or two academic years for part-time students. It comprises lectures and practical work on the applications of ionising radiations to Medicine and Health Physics. The Course is open to persons who hold an Honours Degree with Physics as a principal subject, and provides a suitable basis for a career in medical physics. Physicists working with radiations in medicine or industry may be accepted as part-time students. The Course is recognised by the S.R.C. and M.R.C. for the award of Advanced Course Studentships.

Further information and application forms can be obtained from the Secretaries of the Departments of Physics at The Medical College of St. Bartholomew Hospital, Charterhouse Square, London EC1M 6BQ and The Middlesex Hospital Medical School, Cleveland Street, London W1P 6DB. 9120(D)

UNIVERSITY OF SOUTHAMPTON
M.Sc./DIPLOMA IN BIOLOGICAL AND CHEMICAL METHODS IN PEST CONTROL

This one-year course, which commences in October, is open to graduates in Biology, Chemistry, Biochemistry, Agriculture or any related subject. It provides instruction in modern techniques and methods used in pest management, and is particularly suitable for graduates in Biology or Chemistry who wish to become proficient in relevant aspects of both subjects.

Further information may be obtained from Dr J. W. S. Bradshaw, Department of Biology, Building 3, The University, Southampton SO9 5NH, please quote reference number 1604/R/N.

FELLOWSHIPS

IMPERIAL CANCER RESEARCH FUND
London, England
VISITING FELLOWSHIPS

The Council of the Fund invite applications for Visiting Fellowship to be held in any of the following the Central Laboratories of the Fun at Lincoln's Inn Fields; Mill Hi Laboratories; the Breast Cancer Unit Guy's Hospital; Cancer Epidemiolog and Clinical Trials Unit, Oxfor University; Medical Oncology Unit St Bartholomew's Hospital; or Tumou Immunology Unit, University College London.

These Fellowships will be open t any applicant, irrespective of citizenship who has (or is about to obtain a Ph.D. or its equivalent and who i temporarily or permanently residen outside the UK. Remuneration wil be comparable with postdoctora fellowships in country of origin; th award will be for one year. Return air fares at the lowest practicable rate will be paid for the Fellow an family, and medical insurance wher necessary. The award constitutes Contract of Service namely to undertake specified cancer studies for stated period. Fellowships are no pensionable.

Application to the Director o Research, Imperial Cancer Researc Fund, Lincoln's Inn Fields, Londo W.C.2, England, should be accompanied by full C.V. and list of publications, the names of two referees an account of the applicant's curren and proposed research extending t about 500 words, and a short accoun of the relevance of the above work t the alleviation of cancer. The laboratory or unit in which the candidat wishes to work should be specified Closing date March 31, 1979. 9020(E)

UNIVERSITY OF KEELE
RESEARCH FELLOWSHIP

Polarography of Organic Cation

Applications are invited from Electrochemists with Ph.D. or equivalen experience for a two-year Researc Fellowship (S.R.C. Postdoctoral Research Assistantship) to work with D P. H. Plesch. Salary in scale £3,883 t £4,631 per annum with membership o Universities Superannuation Scheme Further particulars and applicatio forms from The Registrar, The University, Keele, Staffordshire ST5 5BG England. Closing date, March 3, 1979. 9047(E)

UNIVERSITY OF OTAGO
Dunedin, New Zealand
UNIVERSITY POSTDOCTORAL FELLOWSHIPS

The Council of the University invites applications for University Postdoctoral Fellowships tenable in any Department of the University in 1980.

In addition to contributing to current research programmes, the successful applicants will be required to undertake a limited amount of teaching.

The total value of each Fellowship is NZ\$10,000 comprising both emolument and travelling expenses. The maximum amount paid as emolument is NZ\$8,500. This is taxable in New Zealand. The Fellowship is normally for one year but under exceptional circumstances it may be renewed.

Candidates who are offered a Fellowship must have successfully completed their doctorate before taking up appointment. All candidates must have reasonable expectations of completing their doctorate during the year before that for which the Fellowship is offered.

Further particulars are available from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H 0PF, or from the Registrar of the University, P.O. Box 56, Dunedin, New Zealand.

Applications close on **March 1, 1979.**

FELLOWSHIPS (continued)

MRC

Medical Research Council

Training Fellowships Scheme 1979-80

Tenable in the U.K.

The Council invites applications from suitably qualified candidates for MRC Training Fellowships.

Eligibility Requirements –

(candidates must have been ordinarily resident in the UK throughout the period of 3 years immediately preceding the application date)

(1) Graduates in medicine

(2) Graduates in dentistry

From post-registration up to Senior Registrar or at least one year's postgraduate experience

(3) Graduates in science

With PhD or D Phil, or with MSc plus at least 3 additional years' postgraduate experience, up to maximum seniority for a non-clinical academic lecturer

Training Available

For (1), (2) and (3) specialised research training or training in the basic subject relevant to a particular clinical interest

For (1) and (2) at House Officer to Registrar or equivalent clinical academic level a suitable MSc or comparable course

Stipends

For (1), (2) and (3) appropriate point, with increments, on the current NHS medical (House Officer to Senior Registrar) equivalent dental, or current relevant academic scales

Tenure

From 6 months to 3 years (or duration of MSc course)

Further information and application forms are available from Medical Research Council, Training Awards Group, 20 Park Crescent, London W1N 4AL (tel 01-636 5422 ex 240)

CLOSING DATE FOR APPLICATIONS: 28 FEBRUARY 1979.

Late applications cannot be considered.

9080(E)

UNIVERSITE CATHOLIQUE DE LOUVAIN
Belgium

FELLOWSHIP IN PHARMACOLOGY

Applications are invited for a Post-doctoral Research Fellow to investigate the pharmacology of receptor-response coupling processes in cardiac and smooth muscles in the field of digitalis and adrenergic receptors, under the supervision of Professor T GODFRAIND.

The appointment is tenable for at least one year commencing as soon as possible in 1979.

Salary is within the range 30,000 to 35,000 Belgian francs.

Applications with curriculum vitae and naming 3 references should be sent to the

Rector of the University
Halles Universitaires
Place de l'Université, 1
1348 LOUVAIN-LA-NEUVE
Belgium

A further copy should be sent to Professor T. GODFRAIND, Université Catholique de Louvain, Laboratoire de Pharmacodynamie Générale et de Pharmacologie, Avenue E Mounier, 73 UCL 7350, 1200 BRUXELLES, Belgium, from which informations can be obtained. 9063(E)

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF PHYSICS

RESEARCH FELLOWSHIP IN THEORETICAL PHYSICS

Applications are invited for a post-doctoral fellowship to study extended solutions, such as solitons and instantons, of non-linear field theories, with a view to applications in statistical physics The fellowship is tenable from October 1, 1979, for up to three years, at an initial salary on a range up to £4,382 per annum (under review).

Further particulars may be obtained from Dr D J Wallace.

Applications should be sent to Mrs E C. P Sears, Staffing Section, The University, Southampton SO9 5NH by March 2, 1979, quoting reference 1605/R/N, giving a brief curriculum vitae and the names of two referees.

9046(E)

ASSISTANTSHIPS

UNIVERSITY OF OXFORD
DEPARTMENT OF THEORETICAL PHYSICS
RESEARCH ASSISTANTSHIPS IN SOLID STATE THEORY

Applications are invited for two Research Assistantships in the Solid State Theory Group. These are funded by the Science Research Council to support an ongoing research programme on the theory of phase transitions and disordered systems, and to give theoretical support to experimental programmes in the Clarendon Laboratory. The appointments are temporary and tenable for one to two years from October 1, 1979. The salary is on the Research Support Scale 1A, currently £3,383 to £6,555 per annum (with U.S.S. membership).

Applications, with the names of two referees, to Professor R. J. Elliott, Department of Theoretical Physics, 1 Keble Road, Oxford, by January 31, 1979. 9084(P)

GRANTS & SCHOLARSHIPS

IMPERIAL CANCER RESEARCH FUND
BURSARIES FOR TRAINING IN RESEARCH

A small number of Bursaries will be awarded at the laboratories in Lincoln's Inn Fields and Mill Hill for full-time studies leading to higher degrees in research fields relevant to cancer, that include chemistry, cell and molecular biology.

The awards will be tenable for three years from October 1, 1979 with a non-pensionable grant of £2,952 a year (subject to tax) and, in some cases, additional allowances

Applications are invited from British subjects normally resident in the U.K and not over 25 years of age, who hope to obtain First or Upper Second class Honours Degrees in Science in 1979.

Further details and application forms available from

The Personnel Officer
Imperial Cancer Research Fund
Lincoln's Inn Fields
London WC2A 3PX

Completed application forms should reach the Director of Research at the above address not later than February 14, 1979. 9019(H)

DUBLIN INSTITUTE FOR ADVANCED STUDIES
SCHOOL OF THEORETICAL PHYSICS

Applications are invited for

RESEARCH SCHOLARSHIPS

tenable in the School during the academic year 1979–80. A limited number of stipends will be available. These awards are normally made at postdoctoral level.

For further particulars and Forms of Application candidates should apply immediately to **The Registrar, Dublin Institute for Advanced Studies, 10 Burlington Road, Dublin 4, Ireland.**

Completed applications should reach the Registrar not later than March 30, 1979.

NICHOLAS COPERNICUS
VOLUME II ON THE REVOLUTIONS
AN ENGLISH TRANSLATION BY
EDWARD ROSEN

It is nearly 500 years since Nicholas Copernicus, the father of modern physics, dedicated to His Holiness Pope Paul III, his theories on physics in De Revolutionibus Orbium Coelestium.

Now for the modern academic, unversed in mediaeval Latin, Professor Rosen has produced a new translation, together with a detailed commentary on the complete Latin text.

This is the 2nd volume in a planned 3 volume set of the complete works of Copernicus organised by the Polish Academy of Sciences. Printed and bound to a very high standard, it is a work of great scholarship and art in its own right, and a fitting companion to Volume I, the full colour facsimile edition published in 1972.

M MACMILLAN PRESS

Not just an instrument... a totally new Du Pont LC system.

Du Pont's new high-performance Model 850 gives you full visual display instant adjustment, all the versatility, reliability and speed you want

This new Du Pont LC system gives the operator immediate call-out knowledge of all key operating parameters and the ability to change those parameters while the system is running.

Other features of the Du Pont 850 include

- a precision constant-volume 3-piston pump
- microprocessor control of components
- immediate operator access while system is running
- built-in computerised diagnostics
- automatic gradient programming.

The new Du Pont 850 LC is designed to meet the demanding requirements of the research scientist as well as the special needs of the quality control analyst. The chromatographer is in total charge-with authorit to change vital parameters without interrupting data reporting.

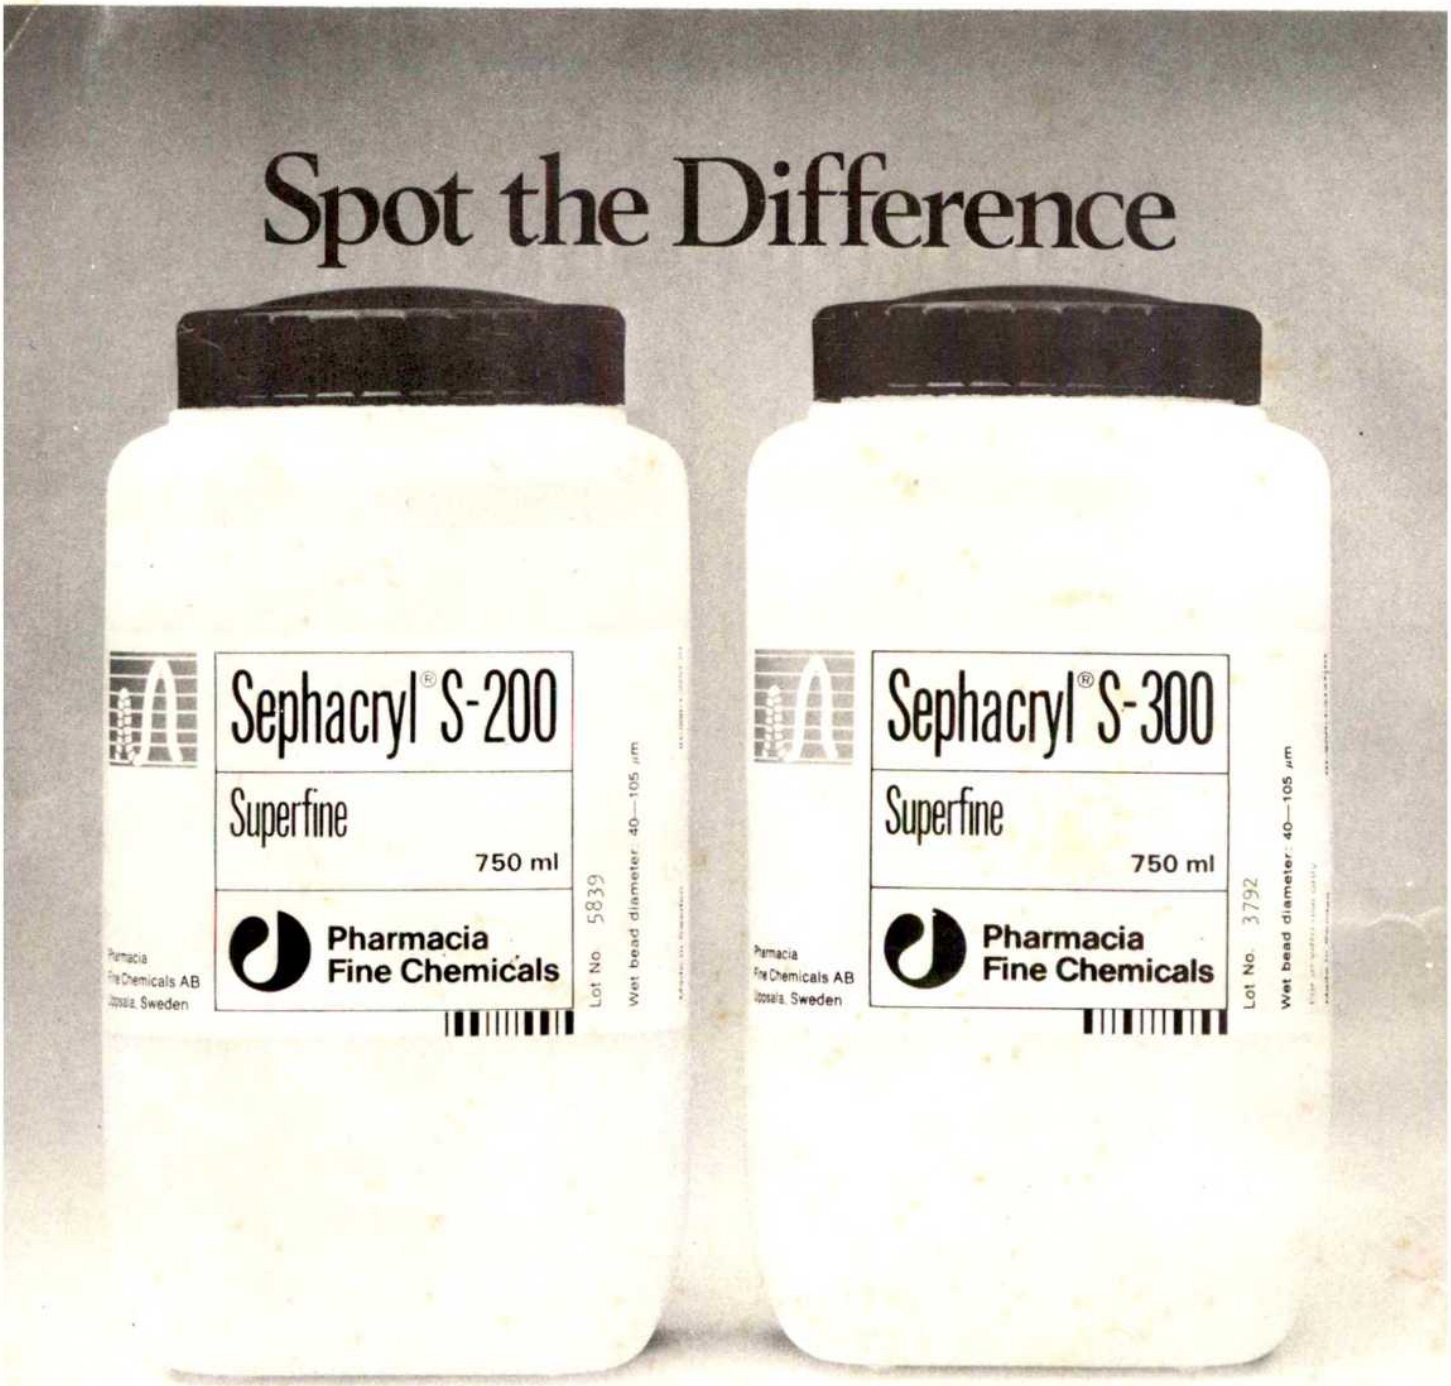
Haemopoietic cell interactions



Sephacryl®

the different medium for gel filtration

- Faster separations: Sephacryl has speed and resolution to spare; separates proteins 5–10 times faster than conventional media.
- Faster packing: Sephacryl is pre-swollen, ready-to-use and packs fast.

Use Sephacryl S-300 Superfine for separations up to an exclusion limit of 1.5 million for globular proteins; ideal for serum proteins. Use Sephacryl S-200 Superfine up to an exclusion limit of 250,000 for globular proteins.

When you use Sephacryl, the difference is clear. Find out more about Sephacryl from your usual supplier of Sephadex®, Sepharose® and other separation media.

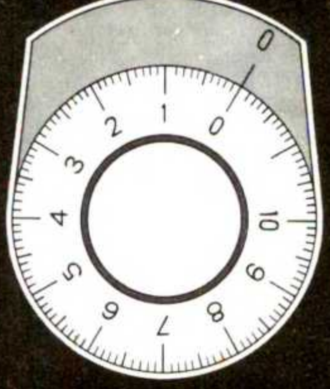
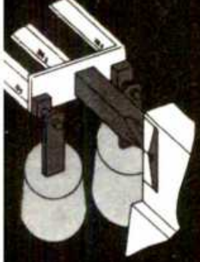
The fast get faster.



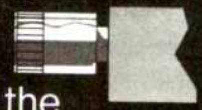
Now the Ohaus Dial-O-Gram 1600 Series has a 10-gram dial; you can read to 0.1 gram directly, so every measurement is easier, faster.

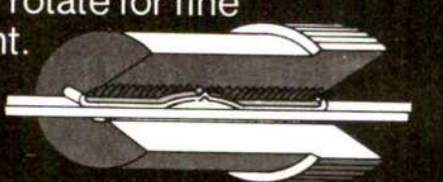
We've also increased capacity to 2610 g with three weights that are easily attached, and store conveniently in the contoured base.



We've kept the over 20 special advantages that make the Dial-O-Gram 1600's all best-sellers.

For example, a lever system to make these Ohaus balances insensitive to out-of-level conditions. Or the patented Ohaus tare poise: it's internally threaded and contains a flat spring which allows you to slide it along the beam for rough taring and rotate for fine adjustment.





If you'd like to find out how beautifully engineered a balance can be, write:

Guide to authors

- Review articles should be aimed at a relatively wide readership. Many reviews are invited, but submitted articles may also be accepted; it is advisable to consult us before writing a review article.
- Articles may be up to 3,000 words long with at most six displayed items (figures and tables); they are reports of major research developments.
- Letters are brief reports of original research of unusual and wide interest, not in general longer than 1,000 words; they have at most three or four displayed items.
- 'Matters Arising' permits short discussion (up to 300 words) of papers that have recently appeared in *Nature*.

Articles should be accompanied by an abstract of not more than fifty words. Letters should begin with a paragraph giving the background and main conclusions in terms intelligible to as wide a readership as possible.

Manuscripts may be submitted either to London or Washington. Three typed copies should be submitted, each including lettered copies of figures. Typing (including references) should be double spaced. The title should be brief and informative. Pages should be numbered. References, tables and figure legends should start on separate pages. Experimental detail vital to the paper yet which would interrupt the narrative is best placed in the figure legends. Units should conform to the Système International. Greek characters should be identified in the margin on their first appearance. Equations should occupy single lines if possible; exp (a) is preferred to e^a if 'a' is more than one character.

References are indicated by superscripts in the text. See any contemporary *Nature* for style, but note:

(i) only one reference number need be used if the reference is to several papers by identical authors.

(ii) first and last pages of references should be cited.

Abbreviations should follow the *World List of Scientific Periodicals*, fourth edn (Butterworth, 1963-65). Symposia are often difficult to refer to and only published or soon-to-be-published volumes should be mentioned in references. Their publisher and place of publication should be clearly indicated. 'Personal communication' and 'unpublished' should be incorporated in text.

Artwork should be sent with the manuscript and clearly marked with author's name and the figure number. Line drawings should be either photographic prints or in Indian ink on heavy cartridge paper, tracing paper or similar materials. Most figures are reduced to one column width so originals should be about as wide as a page of *Nature*. To enable figures, particularly maps, to be edited in the same style as the text, they should contain only essential material. Ideally, an unaltered original and three lettered copies should be provided; labelling on half-tones should, if possible, be avoided entirely. Magnifications quoted should be for the figures as submitted. We are always glad to see artwork for possible use on the cover, but cannot guarantee its return.

In order to save on postal expenses we return only the top copy and artwork of manuscripts that we cannot publish.

Nature's publishing policy is outlined in **258,**1 (1975) and **264,** v, 11 Nov. (1976).

Specific antibody-secreting cells generated from cells producing immunoglobulins without detected antibody function — *J.-C. Antoine, C. Bleux, S. Avrameas and P. Liacopoulos* 218
Murine embryonic B lymphocyte development in the placenta — *F. Melchers* 219
Augmentation by interferon of human natural and antibody-dependent cell-mediated cytotoxicity — *R. R. Herberman, J. R. Ortaldo and G. D. Bonnard* 221
Primary sensitisation and restimulation of human lymphocytes with soluble antigen *in vitro* — *E. J. Hensen and B. G. Elferink* 223
Immunochemical quantification of *in vitro* neutrophilic granulocyte differentiation — *J. M. Kinkade, Jr, K. L. Kellar and E. F. Winton* 225
5,6-Epoxyretinoic acid opposes the effects of 12-*O*-tetradecanoylphorbol-13-acetate in bovine lymphocytes — *P. W. Wertz, T. W. Kensler, G. C. Mueller, A. K. Verma and R. K. Boutwell* 227
Migrating epidermis produces AB_2 collagen and requires continual collagen synthesis for movement — *K. S. Stenn, J. A. Madri and F. J. Roll* 229
Survival and development of ciliary ganglion neurones grown alone in cell culture — *R. Nishi and D. K. Berg* 232
GABA and glycine may share the same conductance channel on cultured mammalian neurones — *J. L. Barker and R. N. McBurney* 234
Acetylcholine receptors in organ-cultured human muscle fibres — *S. G. Cull-Candy, R. Miledi and O. D. Uchitel* 236
Is the red cell calcium pump regulated by ATP? — *S. Mualem and S. J. D. Karlish* 238

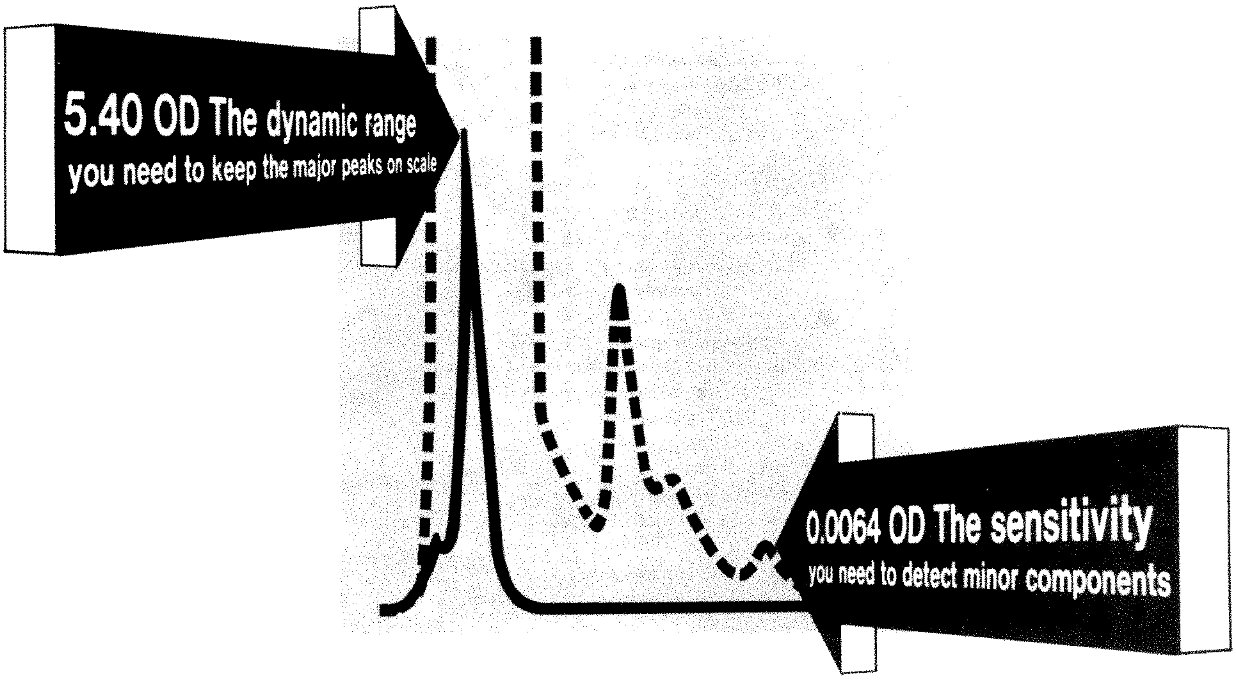
What's new—radioactivity measurement xvii

Newly on the market xviii

Now you can have it both ways!



Pharmacia Dual Path Monitor UV-2

has a unique flow cell with two optical path-lengths for new versatility in UV-monitoring.

- Monitor absorbance quantitatively up to 20 OD units full scale with a sensitivity of 0.005 OD units full scale at the same time, in the same run.
- Monitor at 254 nm and/or 280 nm with two completely independent measuring systems.

The Dual Path Monitor UV-2 has all the other features you expect of a high performance monitor: stability, cold room operation convenience and compact design. For less-demanding applications you can choose the Pharmacia Single Path Monitor UV-1 with a choice of 3 mm or 10 mm flow cell and operation at 254 nm or 280 nm.

Find out more about the practical advantages of column monitoring with the UV-2 and UV-1 Monitors. Ask about the Pharmacia Recorders too.

The next generation of weapons

In the late 1960s there was widespread debate in the United States on the advisability of installing defences against intercontinental ballistic missiles (ICBMs). At that time the intentions were to install radars around sites to be defended and to fire nuclear-armed rockets at any incoming missile. A defending rocket would not necessarily have to score a direct hit on an attacker—a nuclear explosion in its vicinity would suffice.

Such an anti-ballistic missile, or ABM system would have cost an immense amount and could have hardly guaranteed 100% protection. Further, its very existence would have been an encouragement to the nuclear superpowers to find means of rendering it ineffective. On the other hand, even a partial defence of a major constituent of a nation's deterrent was not to be lightly dismissed. In the event, after long and highly-informed public technical discussions, it became clear that neither superpower was strongly committed to ABM, and a bilateral treaty was signed in 1972 severely restricting deployment.

Military technology has not stood still, however, and new ways of attacking targets such as ICBMs have recently been the subject of a growing amount of interest. Are lasers or particle beam weapons a serious option? Research is being carried out in the United States and almost certainly in the Soviet Union to try and answer this question, and recently debate has moved into the public arena, notably with Richard Garwin's article on beam weapons in the October 1978 issue of the *Bulletin of the Atomic Scientists*, and with a series of articles in *Aviation Week*, also in October, on beam weapons research.

A report has recently been issued by MIT's Program in Science and Technology for International Security (*Particle Beam Weapons*, obtainable from the Department of Physics, MIT). In it, a study group reports in technical terms on the pros and cons of beam weapons in the environments both of space and on the ground.

A beam weapon damages its target by cracking its outer shell, by damaging the electronics or by exploding the warhead's trigger. Typically, to do any or all of these things with a beam of area one square metre, of the order of 100 megajoules would have to be delivered. This is not impossible. On the ground jet engines could be used; in space 60 kilograms of high explosive detonated per second would provide the necessary energy per pulse.

Propagation is more problematical. In space, charged particles are of no use. They leave an opposite charge on the generator which attracts them back towards the gun: it is estimated that a 1GeV, 1,000 amp electron beam with a 1-cm radius would get only a metre beyond the accelerator's exit port. Even if a charged particle beam could propagate, it would be degraded over thousands of kilometres by Coulomb repulsion, and deflected by the geomagnetic field which is imperfectly known in space.

Neutral beams don't suffer the same problems, but even so, gamma-rays and neutrons are not easily concentrated to square-metre cross-sections at thousands of kilometres. Hydrogen atoms look more promising. They can be accelerated in a linear accelerator to several hundred MeV as hydrogen with a second electron in the 2s state, or H^-. The beam can then be aimed with a magnetic lens and the electrons stripped by passage through gas. The divergence introduced by stripping leads to a less than ideally concentrated beam, but even so the components of a hydrogen-beam system appear, in the words of the report 'physically feasible'.

Within the atmosphere, charged beams ionise air and this ionisation makes propagation possible. On the other hand the beam is degraded both in energy and cross-section by scattering. What can happen, however, is that a beam of, say, electrons depositing energy along a path through the atmosphere heats that channel, and within a small fraction of a second air density has dropped to a tenth, or even less of normal. In effect, a hole can be bored through the atmosphere, and for perhaps one-tenth of a second can permit pulses of electrons to travel relatively unimpeded. Many questions remain to be answered, but the possibility of an electron beam of a few thousand amps, consisting of ten thousand or more 100-nsec pulses, being able to damage an incoming missile 'cannot be excluded'. Nor, the group find, is there any compelling reason to conclude that exoatmospheric accelerators for H^- atoms or ground-based electron accelerators could not be built at some time in the future.

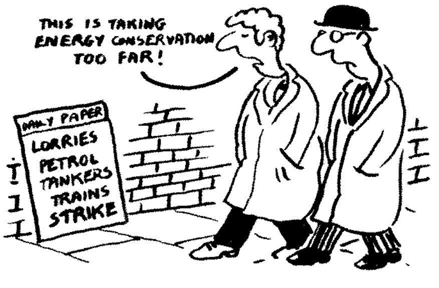
Even if the system can be made to work, however, it has to do so in conditions of war. In space a hydrogen beam might be used either against satellites or to attack ICBMs. At ground level an electron beam might be used as a terminal defence against ICBMs or, at sea, to protect a ship against cruise missiles. In all instances a direct hit is called for (which means accuracies from radars of up to a few parts in a million), and even after such a hit there may be no immediate indication of success. And if the beam misses, it seems near to impossible to determine by how much. Further, the system is open to all the jamming measures that were once discussed in the ABM debate and if the accelerator were in orbit and receiving instructions from the ground that link would be particularly vulnerable. What is more a hydrogen beam would be completely disrupted by the slightest amount of air in space, so a defensive measure could be to fire an explosion in the upper atmosphere, lifting air into space.

The ABM debate is being replayed. An immensely difficult and expensive technical mission, with serious questions at every turn, will be ventured into for fear that the other side just possibly might secure an advantage. There are powerful forces to move the programme forward and spend a lot of money; and for all we know there could be success at the end of the road. There is an arms-control means of stopping development, however. The 1972 treaty noted that if ABM systems 'based on other physical principles' emerged, discussions would be held on limiting such systems. Beam weapons clearly fall into this category. Talks should start soon, even if at present there are no plans for deployment.

Low energy, but lots of loot in UK forecast

Energy needs in the UK in the year 2000 will be at most 3% more than in 1976, and may even be 6% less, according to a report published by the International Institute for the Environment and Development last week. The report emphasises the savings that can be made by introducing proven conservation technologies, and allows for a trebling of Britain's gross domestic product (GDP). In contrast, the present official forecast of the Department of Energy (DOEn) projects an energy growth of some 35% to 70% by 2000 after allowing for a 20% saving through conservation measures.

The IIED forecast may nevertheless not be extreme. The DOEn admitted last week that their 20% conservation figure was a rough one, and said that they had been waiting for nearly a year for a response to it. Their figure was based on consumer research by the Electricity Council and the Gas Boards, advice from the Department of the Environment on the progress of insulation of buildings, "and many other sources", but was open to revision. The IIED report would have its impact on the forthcoming Green Paper on energy futures, said a spokesman, although there was too little time to take it fully into account.



Mr Gerald Leach, the author of the report, said last week that far from having an energy gap the UK had "a great deal of room to manoeuvre on supply options, without extreme measures". Much of the necessary conservation technology — such as heat pumps for domestic space heating and efficient internal combustion engines—will become available in the 1980s, he argued, when the devices will begin to replace existing equipment. Cost savings in running the technology will lead to its adoption by the consumer with little or no encouragement from the givernment, he argues. "We have found that it is astonishingly easy to save energy" said Mr Leach. "We began this work as energy pessimists, but now we are optimists".

Many of the measures are emerging as a result of the 1973 oil crisis, says the report, when it became fashionable as well as expedient to consider ways of saving energy. The effect of this work is mostly yet to come. The Royal Institute of British Architects, for example, has enthusiastically adopted conservation, an attitude which has already resulted in buildings using half as much energy as before for only a 2 to 3% cost penalty, but building stock is replaced only slowly. In the home, lights, cookers, and heaters will soon enjoy "very substantial increases in efficiency". Small-scale heat pumps, such as the one being designed by the Gas Boards, are "at an advanced stage" and will make a dramatic impact. The motor industry is designing cars with a 50% reduction in fuel consumption. Industry uses 40% of primary energy, "but a large proportion of that is in heating poorly insulated buildings, where strict regulation is on the way" says Gerald Foley, one of the team that produced the report. Indeed the government has already adopted measures which will improve industrial conservation. "The result is that all across the board there is slack" said Mr Leach. "For example, we predict a need for only 26-30 GW by 2000, whereas the DOEn assumes 83 GW. Quite clearly there is no need for nuclear; we have assumed 4½ to 6½ GW to keep the industry in business. The breeder reactor could be postponed indefinitely." Even renewable sources were not strictly necessary: the report assumes 4-6 million tonnes of coal equivalent produced in 2000 from alternative sources, compared with 10 in the DOEn projection.

The report may, however, have assumed unrealistic substitution rates. The most uncertain element may be the cost of the new technology, and of

---

A low energy strategy for the UK (Science Reviews Ltd and IIED) £7.50. Obtainable from IIED, 10 Percy Street, London W1.

Britain's energy optimist

Gerald Leach, author of *A low energy strategy for the UK* (see above), may see himself as an energy optimist—but the *Financial Times* last week saw it differently. Thinking no doubt of the markets lost to the energy supply industry, the subeditor had headlined the story about Leach's report "Bleak forecast for UK energy". But Gerald Leach's interests do not lie with big business.

Gerald Leach is 44, and left science writing and broadcasting (for the BBC and the *Observer*) in 1972. At the *Observer* he had become interested in the works of Commoner and Ehrlich, and had accumulated "shelves of fascinating books with no time to read them. As a journalist I felt I was skating over an ocean." Then he met a representative of the Ford Foundation at the Stockholm environment conference, cheque book in hand, and his new career began.

He produced a series of reports for various bodies on energy matters, including *Energy and Food Production* (for IIED), *Fuel conservation: options for aviation* (for OECD), *Nuclear energy balances in a world with ceilings* (for IIED), and gave evidence on energy futures to the Windscale inquiry on reprocessing. He defended "Limits to growth" at the Royal Society, did "a big splash" in the *Observer;* but "I began to feel uncomfortable. Early on he realised the importance of "saturation" effects—such as a ceiling on the number of cars, or the temperature of a house, or conservation. Growth might limit itself.

"Early in 1976 I'd finished a project and I went down to Her Majesty's Stationery Office to read all the government reports on energy. There turned out to be only 4 pages on futures." But the US was much further ahead. "My first task was to convince the Ford Foundation that we were so far behind". Then he got the grant, and the study was under way under the wing of the International Institute for the Environment and Development. "The original proposal to Ford was on alternative sources with a bit of conservation" said Leach. "Then we began to feel strongly about disaggregation", calculating energy futures by adding up all possible uses rather than using macroeconomic trends. It also emerged that previous reports were unduly moderate on conservation. The result was the low energy prediction just published. □

0028-0836/79/0277—0162$01.00

fuels which will affect substitution. "We will be attacked by economists" admits Leach. The report has adopted apparatus replacement rates of some 5% per year after the new technology becomes available. Thus heat pumps have a 15-20% penetration of the market by 2000. But in housing the report allows until 2010 before all houses have 4 inches of loft insulation, and cavity walls are filled.

So far, the Department of Energy response has been friendly, and mildly defensive. "My feeling is that there is a lot of work to do yet in conservation in our methodology" said a spokesman. "We are only scratching the surface . . . But has Gerald Leach only taken the most favourable answers from all his inquiries? In our last green paper we took advice from the department of transport, the oil companies, and car manufacturers among others. Most thought that 20% conservation was ambitious. Mr Leach is applying current best practice across the board, and concludes that one can increase that 2 or 3 times. That may be wishful thinking."

The team responsible for the IIED report consisted of Gerald Leach, Christopher Lewis, Frederick Romig, Ariane van Buren, and Gerald Foley.

Robert Walgate

. . . and the view from across the Atlantic

Forecasts of US primary energy demand in 2000 AD

(in quads = 10^{15} BTU)
(1975 consumption 75 q)

Year of forecast	Source of forecast			
	beyond the pale	heresy	conventional wisdom	superstition
1972	125 *Lovins*	140 *Sierra Club*	160 *AEC*	190 *Fed Power Comm'n*
1974	100 *FF (Zero growth)*	124 *FF (Tech. fix)*	140 *ERDA*	160 *Edison Electric Inst.*
1976	75 *Lovins*	89-95 *v H and W—Lovins*	124 *ERDA*	140 *Edison Electric Inst.*
1978	33 *Steinhart (for 2050)*	63-77 *CONAES panel (for 2010)*	95-100 *CONAES, DOE-IEA*	123-124 *RDE—Ralph Lapp*

Energy forecasts have been falling in many countries, not only the UK. Amory Lovins has communicated this table of US forecasts for the year 2000, produced by various bodies over the last six years. "Read diagonally, the matrix has considerable predictive power" says Lovins. The September 1978 Department of Energy forecasts were not known when the table was first prepared. However, there is considerable subjective judgement involved in the choice of columns and of forecasts to fit them. Read literally, the matrix predicts that the conventional 1980 US forecast for the year 2000 will be some 70 quads, less than 1975 consumption.

Abbreviations used: AEC, Atomic Energy Commission; FF, Ford Foundation; ERDA, Energy Research and Development Administration; vH and W, von Hippel and Williams; CONAES, the Committee on Nuclear and Alternative Energy Systems of the US National Research Council; and DOE, Department of Energy. In 1976 Lovins' two forecasts were private (75q) and public (95q, published in *Foreign Affairs*). In 1978 the CONAES panel used three scenarios, as did the DOE (varying with projected oil price). ☐

Black year for Soviet refusniks

1978 was, in general, a black year for Soviet refusnik scientists, marked by increasing harassment and the imprisonment or exile of a number of the best-known of them. However, the year ended on a note of partial triumph—in the last week of December the "Sunday seminar" for refusniks achieved its long-standing aim of an international meeting with the participation of scientists from USA, France and the UK.

Inevitably a number of the intending foreign visitors failed to receive the necessary visas. Five of the eight would-be participants from the US had their visas revoked—evoking a statement of censure from the Committee of Concerned Scientists saying that it "found it unconscionable for the USSR to seek to prevent American scientists from engaging in scientific discussions with Soviet colleagues". The conference, it claimed, was "an excellent example of the kind of unofficial, non-governmental exchanges provided for by the Helsinki Final Act."

"Non-governmental" exchanges do not fit easily into the Soviet concept of science, and previous attempts of the seminar group to hold an international meeting were less successful. In 1974, no foreign visas were issued and the leading Soviet participants were arrested. Nevertheless, the proceedings of the "Conference that never was" were published in the regular manner, and limited foreign participation was permitted in the April 1977 meeting to commemorate the fifth anniversary of the founding of the seminar.

The apparent acquiescense of the Soviet authorities with regard to last month's meeting seem due rather to international pressure than to any change of heart. Continuing routine surveillance of the venue—the flat of Viktor Brailovskii—during the seminar, and a thorough police search with confiscation of his recent scientific material and his Lenin library ticket made this clear. A number of other intending participants suffered like harassments.

Nevertheless, the meeting itself took place. The main purpose of last months gathering was to bring the refusniks abreast of recent Western developments.

The chosen title "collective phenomena" allowed a wide range of subjects. The US participants presented work in statistical physics and vortex motion in superfluid ^{4}He, while the French contributions ranged over crystal physics, axiomatic quantum field theory, one-dimensional conductors, and what one participant described as a "very pretty" result in percolation theory. Since this last contribution required no specialist background, it was of particular value to the refusniks, many of whom have inevitably fallen irrevocably behind in their original field, and who therefore wish to extend their acquaintance with other subjects.

Local contributions were, understandably, somewhat hampered by the extremely restrictive nature of refusnik life—lack of access to experimental facilities and to new results in particular. Nevertheless, a wide range of subjects was attempted, including solitons, plasma physics, and quantum field theory. Yurii Orlov, one of the few non-Jewish members of the original seminar group, could not be present in person—he is at present serving a 12-year sentence for "anti-Soviet agitation and propaganda". A paper of his on "Wave logic", an alternative to conventional two-valued logic, more appropriate to quantum mechanics was presented in absentia.

Another gentile who has always taken a keen interest in the Seminar, is academician Andrei Sakharov. To the delight of all participants, Sakharov attended the first session. Other notable Soviet participants included Aleksandr Lerner, Grigorii Rozenshtein, Yurii Fishman, Yurii Gol'fand and Yakov Al'pert.

Psychosurgery supporters sued for malpractice

David Dickson reports from Boston on a little-publicised court case that has revived debate on the psychiatric use of surgery

Two prominent supporters of the use of surgery to control the behaviour of individuals are being sued for malpractice by a former patient who, it is claimed, is now confined to a mental hospital as a direct result of the treatment that he received.

The charge of negligent treatment has been made against Dr Vernon H. Mark, Director of the Neurosurgical Service at Boston City Hospital, and Associate Professor of Surgery at Harvard Medical School, and Dr Frank R. Ervin, now Professor of Psychiatry at the University of California in Los Angeles.

Dr Mark and Dr Ervin became the centre of a fierce public controversy in 1967 when, in a letter to the *Journal of the American Medical Association*, written with Dr William H. Sweet, Professor of Surgery at Harvard Medical School, they suggested that brain dysfunction in individuals might have contributed to the urban riots that swept several American cities in the late 1960s—and that people with 'low violence thresholds' should therefore be diagnosed and treated before they contributed to further such tragedies.

Three years later, Drs Mark and Ervin published a book *Violence and the Brain* in which they wrote that they intended to stimulate a "new biologically-oriented approach to the problem of human violence" and that this should lead to a "more rational approach" to the problems of violence.

The suit claiming malpractice has been filed by the mother of Mr Leonard A. Kille, previously a research and development engineer with the Polaroid Corporation. It is being handled by the Washington law firm on which Health Secretary, Mr Joseph Califano, was once a senior partner.

While working for Polaroid, Mr Kille headed a team that was responsible for a number of patents on the land camera. He received treatment, including brain surgery, from the two defendants in 1966 and 1967 and he is generally taken to be the patient 'Thomas R.' described in *Violence and the Brain* as a "brilliant 34-year-old engineer with several patents to his credit", whose treatment Dr Mark and Dr Ervin say represented the first time they were able to demonstrate that systems in the limbic brain both start and stop attack behaviour.

According to evidence presented to a jury which is currently considering the charges in a Boston court-room, Mr Kille was referred to the Boston General Hospital in 1966 after a history of epileptic seizures and outbursts of violent behaviour mainly directed towards his wife. He was diagnosed as having psychomotor seizures and 'personality pattern disturbance', and subsequently as suffering from temporal lobe epilepsy.

Following apparently unsuccessful attempts by the hospital to treat him with a variety of drugs, Dr Mark and Dr Ervin implanted a series of electrodes in his brain, the stimulation of certain of which relieved his aggressive symptoms. They subsequently performed an operation by making small bilateral lesions in his medial amygdala through heating the electrodes.

Immediately after the operation, according to evidence presented in the court, Mr Kille's behaviour seemed to have improved. At one point for example, he said that he 'felt like a new person'. However, shortly after his release from hospital his violent tendencies returned, and a month later he was admitted to a west coast hospital where he was described as "hallucinated, delusional and confused" and diagnosed as schizophernic and paranoid.

A succession of hospitalisations and subsequent discharges followed, with continued signs of aggressiveness and belligerence. Mr Kille was eventually placed under permanent care at the Bedford Veterans Administration hospital, 25 miles north of Boston, where he is now confined. In the suit that has been filed on his behalf, it is now claimed that he was "rendered of unsound and unbalanced mind" as a direct result of negligent treatment by Dr Mark and Dr Ervin.

In particular, it is alleged that the surgeons failed to inform him fully of the risks and ramifications of the surgical procedures that they were recommending, and that they therefore failed to obtain his informed consent. A charge of battery resulting in permanent injury and incapacitation has been made and damages of $2 million are being sought.

During the court proceedings, the plaintiffs have claimed that the surgeons considered that they were treating a behavioural, rather than a medical, condition (in their book they describe T. R.'s chief problem as being his violent rage), and that although the procedures they were adopting should have been described to Mr Kille and his wife as experimental this was not in fact done.

Suggesting that there might also have been a conflict of interest between medical and scientific priorities, the plaintiffs have pointed out that Dr Mark told a neuroscience seminar in December 1966 that inserting electrodes in the brain for therapeutic reasons served a dual purpose since it had "real value both to the patient and to our scientific enquiry".

They have also quoted a passage from a later printing of *Violence and the Brain* in which Dr Mark and Dr Ervin state that "four years have passed since the operation, during which Thomas has not had a single episode of rage. He continued, however, to have an occasional epileptic seizure with periods of confusion and disordered thinking". This indicates that the surgeons were primarily concerned with altering their patient's behaviour rather than his medical condition—and that they felt they had successfully treated the former.

The defendants have replied to the various charges by saying that Mr Kille was diagnosed as suffering from temporal lobe epilepsy, which gave rise to his seizures, and that given the state of medical knowledge at the time, as well as the patient's failure to respond to more conventional treatment, the surgical procedures that they took were appropriate.

They also claim that during the meeting at which Mr Kille and his wife formally gave their consent to the amygdalectomy operation, it was explained that there was roughly a one-third chance that the operation would successfully relieve his symptoms, a one-third chance that there would be some improvement, and a one-third chance that there would be no improvement or a deterioration.

Finally responding to the published description of the patient T. R., Dr Mark told the jury that this was a composite case history with detail taken from a number of patients, and that it should not be taken as describing exactly the case of Mr Kille.

The whole case has revived the debate on the ethics of psychosurgery which flourished at the beginning of the decade. Two years ago, following widespread public concern on the issue, the National Commission for the Protection of Human Subjects of Biomedical and Behavioural Research issued a report which, to the surprise and disappointment of some and the delight of others, gave psychosurgery its approval in some circumstances.

Though professing to an initial scepticism, the report drew on studies showing that a large number of

0028-0836/79/0277—0164$01.00

patients had been successfully relieved of pain or depressive symptoms as a result of such surgery to support the contention that it was a potentially beneficial therapy.

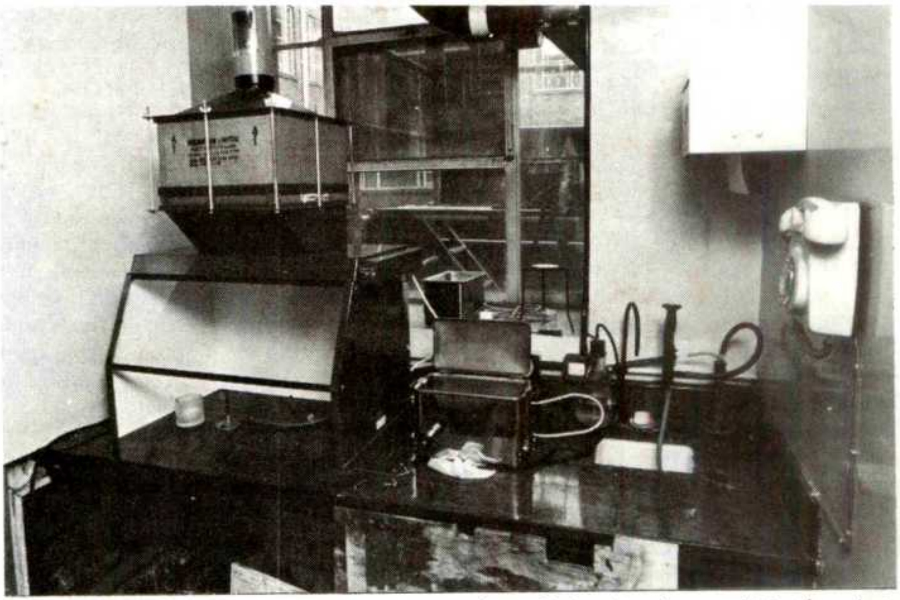
Others still claim, however, that although psychosurgery may be effective in alleviating symptoms such as pain and depression, this is frequently at the expense of sacrificing other aspects of the individual's identity, such as emotional responsiveness and creativity. It is also claimed that the psychosurgeons approach reduces social behaviour to a purely biological phenomenon, thus denying a range of environmental factors which alternative forms of treatment, such as psychotherapy, can take into account.

"There is no scientific foundation for attempting to control a specific aspect of social behaviour by destroying a portion of the human brain", says Dr Stephan Chorover, Professor of Psychology and Brain Science, at the Massachusetts Institute of Technology, who has given evidence during the court hearings. "The main thrust of this approach to social problem solving is that it tries to localise the problem in 'defective individuals' and therefore embodies a decision not to search for problems in the larger social system".

Whichever way the court decision goes, it is unlikely to resolve the wider philosophical issues surrounding the use of psychosurgery, since the matters on which the jury has been asked to judge relate essentially to the adequacy of the medical procedures followed prior to and during the treatment.

At the same time, however, it could provide a precedent for further legal actions. Already a second case is being brought on behalf of a girl who, at the age of 19 but without her consent, and after a series of electric shock treatment but minimal psychotherapy, had a cingulotomy—a lesion of the cingulum—performed by another Boston surgeon. This case is scheduled to be heard shortly. ☐

More dangerous smallpox labs?



Above: the smallpox laboratory at Birmingham University from which the virus escaped last August. A possible route of infection—through a cable duct—appears bottom left.

AS FAR as the World Health Organisation (WHO) is aware there are now nine laboratories in the world holding live smallpox virus; but only three of them—those in London, Hamburg and Atlanta—are known to match up to WHO smallpox laboratory safety recommendations. The laboratories at St Mary's Hospital, London and the Centre for Disease Control, Atlanta are to become WHO collaborating centres for poxvirus research; so is the Research Institute of Viral Preparations, Moscow, which is currently making modifications to come up to the WHO standard.

The Institut fur Schiffs und Tropenkrankheiten in Hamburg, the Rijks Institut voor de Volksgezondheid, Bilthoven, the Netherlands, the US Army Medical Research Institute for Infectious Diseases and the American Type Culture Collection are all considering either destroying or transferring their viruses to one of the WHO collaborating centres. The latter three laboratories have not been visited by WHO. The other two laboratories currently holding smallpox virus are in Peking (which WHO has no plans to visit) and South Africa, which does not come up to standard, is storing the virus, but doing no research. Only the Centre for Disease Control in Atlanta is doing smallpox research at the moment.

The risks of laboratory infection should be seen in proportion, however. The WHO smallpox eradication unit has reduced the death rate from the disease from one million per year 10 years ago to probably zero this year. And smallpox is not an easily transmitted disease: it is not as infectious as flu or measles, for example. ☐

● **Correction:** six white coats per laboratory worker were recommended by the Howie report on a code of practice for the prevention of infection in clinical laboratories, not the Godber report on the handling of dangerous pathogens, as indicated in last week's leader.

Scientist may sue over "Golden Fleece" award

THE Supreme Court has agreed to rule on whether Senator William Proxmire committed libel when he made a "Golden Fleece" award to a scientist engaged in a study for NASA of teeth-clenching by monkeys.

Senator Proxmire, who is chairman of the Senate Appropriations Subcommittee responsible for the budgets of both NASA and the National Science Foundation, has frequently made such awards to esoteric- or naive-sounding research projects, which he claims to be an unncessary drain on the public purse. One recipient of the award was a research scientist, Dr Ronald R. Hutchinson, of Kalamazoo, Michigan, who, according to Mr Proxmire, has received more than $500,000 in federal funding for research that includes measuring the latent aggression of laboratory monkeys under various conditions by recording electrical impulses in the jaw muscles.

Although NASA has said that the work was of particular importance in its efforts to identify aggressive personality traits in selecting crews for long space flights, Mr Proxmire called the research an outrageous example of "wasteful, extravagant, stupid spending".

A lower court rejected a libel action for $8 million brought by the research worker partly on the grounds that he had become a "public figure" by soliciting government grants and publishing occasional articles in professional journals. Senator Proxmire also claimed legislative privilege. The Supreme Court has now agreed to hear an appeal from Dr Hutchinson, who claims that, as a result of the award, he has suffered injury to his reputation, illness, mental anguish and prospective loss of economic advantage. ☐

news in brief

MRC calls for more research students despite poor job market: In a generally bleak annual report, the UK Medical Research Council (MRC) has announced it is to recruit young scientists "despite the current shortage of longe term career openings in the universities". However, the MRC will introduce three new measures to alleviate some of problems of the most able research workers and to bolster confidence that the UK will provide opportunities for scientists of "really high ability to develop their talents". The new measures are: a salary grant scheme to permit university staff to work full time on research projects of a very high standard; a similar scheme to provide a small number of clinical research posts for clinical academic staff in the country's medical schools; and five-year renewable fellowships for "particularly able people" to bridge the period between a researcher's first employment and subsequent permanent post. The MRC aims to appoint three such fellows a year, building up to a total of 15.

The report makes no mention of scientists currently in employment on short term contracts. According to a recent AUT estimate there are 5,000 researchers in the UK on short-term contracts funded by the MRC and an additional 1,700 registered as unemployed with the Department of Employment. (*Medical Research Council Annual Report* 1977-78 (HMSO) £3.75).

Czech Chartist jailed for nine months: Dr Jaroslav Sabata, a former professor of psychology and one of the three spokesmen of the Czechoslovak Charter 77 human rights group, was sentenced last week to nine months' imprisonment on the formal charge of "insulting a police official". Dr Sabata, who was a prominent Communist Party official during the "Prague Spring" of 1968 and who has since served five years of a seven year prison sentence for dissident activities, is a fervent advocate of closer links between the human rights movement in East European countries. His arrest last October near the Polish-Czech frontier took place during a series of meetings between the Czech Chartists and the Polish "Committee for Social Self-Defence". Authorities on both sides of the frontier tried to prevent the meetings.

During the trial, the procurator described Sabata as a "criminal" whose activities threatened the whole Czechoslovak people—a clear indication that his real offence in official eyes is his constant campaigning for personal, political and academic freedom.

Australia restructures its science planning: Following the report of the first inquiry into the functioning of the Commonwealth Science and Industry Research Organisation (CSIRO) since 1949, the Australian Government has announced a restructuring of CSIRO's top management to "facilitate closer liaison between researchers and users of research results, particularly industry". Described as an "update" rather than a "shake-up", the move organises the 37 CSIRO divisions with their staff of 7,000 into five institutes, each with a new director. The old executive structure of five full-time members and four part-timers has been replaced by a new policy-making body composed of three full-time members plus the directors of the new institutes. The identity of the 37 divisions has been preserved and the autonomy of CSIRO is not affected.

The new groupings and their directors are: Institute of Animal Sciences (Dr K. A. Ferguson); Institute of Biological Resources (Mr M. V. Tracey); Institute of Earth Resources (Mr I. E. Newman); Institute of Industrial Technology (Professor Emeritus H. W. Worner); Institute of Physical Sciences (director to be appointed); and the Bureau of Scientific Services (Mr S. Lattimore).

Ustinov on Einstein: Peter Ustinov (right), actor, writer and director, will on 14 March introduce and narrate a special two-hour BBC television programme celebrating the centenary of Einstein's birth. Ustinov, for whom mathematics and science were a total mystery when he was at school, has proved to be "a perfect student", according to producer Martin Freeth. The programme will concentrate on general relativity, the most difficult of Einstein's theories and features experimental and theoretical physicists Kenneth Brecher, Wallace Sargent, Irwin Shapiro, Roger Penrose, John Wheeler, Sidney Drell and Dennis Sciama. Written by Nigel Calder, the programme was filmed on location at the 107 inch reflecting telescope at the McDonald Observatory of the University of Texas. The programme will also use supporting film from other research centres showing current research results that support Einstein's theory.

Expanding Third World does not bring unemployment: Developing countries no longer simply sell raw materials in exchange for manufactured goods but are becoming manufacturing nations in their own right, and their increase in productive capacity is now being felt in the industrialised countries. Between 1972 and 1976, imports of manufactured goods to EEC countries increased from $27 billion to $76 billion. Experts consulted by the EEC have now cautioned against imposing trade barriers, saying that European industry must be adjusted to make it more competitive by "transferring production from stagnant or declining industrial sectors to those with a more promising outlook."

The effects on employment, while potentially serious, are held by EEC experts to be insignificant. Industrial employment began to decline in 1965. Using the UK as an example, the job losses attributable to Third World competition are 0.05% in textiles, 0.4% in the shoe industry, 0.8% in cotton fabrics and 1.7% in clothing. The real problem, say the experts, is the shifts caused by the new international division of labour which is causing job changes for European workers rather than unemployment *per se*. (*euroforum*, 12 December, 1978.)

Miners oppose nuclear power station near Newcastle: The National Union of Miners (NUM) is mounting a campaign to oppose a Central Electricity Generating Board plan to build a nuclear power station at Druridge Bay, near Blyth. Mr Sam Scott, secretary of the Northumberland region of the NUM, said: "The CEGB is proposing a nuclear plant on top of one of the biggest combined coal pits in Europe and parallel to parkland held by the National Trust. It's stupid".

But Mr A. D. Nash, of the CEGB's planning department, said the plan was "only an exploration of options". There was no commitment to nuclear power. CEGB projections based on an annual 2%-3% growth in demand indicated that new capacity would be needed by the end of the 1980s which could be supplied either by coal or nuclear power. With the six-year lead times necessary to build new plant, it was necessary to explore the options now, Mr Nash said. The miners, along with the National Coal Board, are seeking assurances from the CEGB that coal consumption in the area will not be cut.

Why the world's deserts are still spreading

The fight against desertification is being held up while the politicians wrangle, **writes Anil Agarwal**

THE hopes generated by the United Nations Conference on Desertification (UNCOD) for achieving zero desert growth by the turn of the century, seem to have all but disappeared in just over a year. UNCOD, held in Nairobi in autumn 1977, was widely hailed as one of the most successful UN conferences of the decade. It created an unprecedented awareness about the magnitude of the growing deserts problem, prompting even US President Jimmy Carter to declare that desertification is "one of the most serious problems of our age." It also made a very significant intellectual contribution, unlike most UN conferences, by increasing the understanding about the processes of desertification.

Now, however, there is disillusionment, inaction and fading of interest, according to Professor Mohamed Kassas, Professor of Plant Ecology at the University of Cairo, who played an important role in the organisation of UNCOD. Professor Kassas, who was recently elected President of the International Union of Conservation of Nature and Natural Resources (IUCN), claims that neither the governments of the countries affected by deserts, nor the rich donor countries who were expected to provide substantial funds, have yet shown any serious commitment to combatting desertification.

Most of UNCOD's recommendations were directed towards national governments. It was hoped, for instance, that each country would set up an official focal point to coordinate its desert-related activities. In many developing countries, however, there is often such a gap in communications that one arm of the government is unaware of what the other is doing. While one ministry may be preparing programmes to control deserts, others may be pushing through agriculture and animal husbandry projects that result in increased desertification. The need for coordination is thus important. However, no African government has yet set up such a focal point.

The plans of the United Nations Environment Programme (UNEP) to set up a consultative group for desertification control (DESCON) have also not proceeded very far. UNEP brought together possible donor and recipient countries in May 1978 for discussions. These countries agreed in principle that a mechanism like DESCON is required to mobilise resources for anti-desertification programmes in developing countries. But few of them have yet officially written to UNEP even to confirm their membership of such a group. In these circumstances, the substantial financial assistance that is required to carry out the numerous programmes suggested at UNCOD, is quite unlikely to materialise.

Politics, both national and international, lies at the heart of this lack of interest. At the international level, there is the growing disillusionment of the rich Western countries with the United Nations system, which is reflected in their growing keenness to channel financial assistance directly to recipient countries through bilateral agreements, instead of through the United Nations agencies. This reaction is setting in partly because of the inefficiency and sluggishness of the UN agencies, but even more so because of their involvement with laudable but contentious issues like the New International Economic Order, which irritate many influential politicians in the West. The same rich countries which are fighting shy of making any commitment to anti-desertification programmes through UNEP have pledged over $2,000 million for the development of the Sahel countries through the Club du Sahel, a non-UN organisation.

At the regional level, it is the lack of political will amongst Third World governments to overcome their political differences with each other that bedevils anti-desert programmes. Realising that neither deserts nor desert people, like nomads, recognise political boundaries, UNCOD had tried to formulate solutions to the desert problems with a transnational perspective. UNCOD therefore proposed giant transnational projects like a green belt across North Africa, another green belt across the Sahel, a joint livestock management programme in the Sudano–Sahelian countries, a joint groundwater management programme covering northeast Africa and the Arabian peninsula, and two projects to monitor desert creep in southwest Asia and south America; and it expected feud-ridden countries like Egypt and Libya, Libya and Sudan, Morocco and Algeria, Arab Yemen and People's Yemen, India and Pakistan, and Chile and Argentina, to co-operate in their implementation.

UNEP had indeed taken the bold step to prepare feasibility studies for these transnational projects and get as many governments as possible to sign formal protocol documents for their

Earthscan

Edge of the Sahara: the bare sand is caused by grazing of livestock and cutting of trees for firewood.

0028–0836/79/0277—0167$01.00

implementation well in advance of UNCOD. As a result, when the conference was convened, there was considerable optimism about the seriousness with which they would be implemented. Since then, however, there have only been statements of good intention by political leaders. President Houari Boumedienne, for instance, had assured Dr Mostafa Tolba, Executive Director of UNEP that Algeria would press ahead with the North African green belt covering Algeria, Egypt, Libya, Morocco and Tunisia. But there are very few signs of the speed and urgency that is required. These five North African countries together lose a total of about 100,000 hectares of productive land to advancing deserts every year, which such a project could prevent.

Nepal has expressed an interest in joining India, Iran, Pakistan and Afghanistan in the south-west Asian desert-monitoring-project but the political unrest in Iran, where the project's headquarters were to be situated, and the sudden change of government in Afghanistan have delayed this project too.

The politically calm Sahelian region is, however, faring relatively better, with a growing institutional base for desert control. An Interstate Committee for Drought Control in the Sahel (CILSS) has been set up which involves senior Ministers, and it is receiving international assistance through the Club du Sahel. Regional scientific research is being undertaken by the new Institut du Sahel situated in Bamako, Mali. The United Nations Sudano-Sahelian Office based in Ougadougou, Upper Volta, is being expanded to help all the countries in this region to undertake desert control projects such as those proposed at UNCOD.

The Institut du Sahel will hopefully become a model for regional cooperation in deserts-related research and training. Since UNCOD, UNEP has organised two training courses for scientists and officials from developing countries, one on sand dune stabilisation in China and another on soil salinity and improved management of pastures in the USSR. Considering the enormous social and ecological differences between different desert regions of the world, clearly it would be much better to set up regional centres for desertification training and demonstration, and organise such courses within the regions themselves.

But because of the difficulties in organising effective regional cooperation in combating desertification outside the Sahelian region, Professor Kassas believes that stress should now be placed on encouraging national anti-desert programmes. These programmes could be integrated with national land and water management schemes which aim to raise and stabilise the productivity of the arid regions. National planners, who have to make the best of scarce national resources, are more likely to be attracted by rational desert development schemes, rather than those which are seen as simply desert control schemes or desert monitoring exercises.

The problem of growing deserts is indeed urgent. In the early stages of desertification, the cost of reclaiming land is relatively modest, but if neglected, the cost climbs steeply, until reclamation becomes economically impractical. Global land-loss from man-made causes is already estimated to cover an area bigger than Brazil. Estimates presented at UNCOD revealed that more than 680 million people are living on land that can no longer support permanent agriculture, or is showing signs of steady deterioration. These lands today produce a very large proportion of the global production of cereals, fibres and meat. It is therefore vital to restore them back to health.

Desertification issues will be raised at yet another international conference in Rome in July, 1979: the World Conference on Agrarian Reform and Rural Development (WCARRD), being organised by the Food and Agriculture Organisation. The latest WCARRD newsletter states: "There is no technology problem. Answers lie in mobilisation of national and international resources and popular participation in anti-desertification programmes. These issues will be on the WCARRD agenda." It can only be hoped that WCARRD will succeed where UNCOD has failed. ☐

Anil Agarwal is assistant director (editorial) of Earthscan.

African chemists hit back at foreign technology

THE conflict of interest between 'foreign' companies in developing countries and their hosts "can, and does, have a significant adverse effect on the growth of industrialisation in many developing countries and is at least one of the major causes of the slow pace of the development of industries in these countries", according to Professor D. E. U. Ekong, Vice-Chancellor of the University of Port Harcourt, Nigeria. And he is not alone in his criticisms. At a recent UNESCO symposium on university-industry interactions in chemistry, all the African delegates agreed that the system of itinerant expatriate advice is totally irrelevant to African needs.

In Nigeria, said Ekong, the law now requires majority Nigerian shareholding in most enterprises as well as significant Nigerian representation in management. Nevertheless, technical management is still dominated by the foreign technical partners who determine the technology and the process, including the raw materials, for the industry. Thus the foreign technical partner plays a crucial role in determining the course of industrial development.

Ekong accused these partners of giving biased advice. Their interests as manufacturers, or even their desire to dispose of equipment obsolete in their own countries, will affect their recommendations. Manufacturing processes that require raw materials or key intermediates from the parent company are often chosen.

The Nigerian desire to reduce their dependence on imported machinery and raw materials is thwarted by the lack of provision for research and development. The foreign technical partner provides all the technical know-how and solves any technical problems. Even where the manufacturing process requires quality control involving chemical or physical analysis, many firms use unqualified foreign technicians. Hence, says Ekong, "chemists in developing countries have very few opportunities".

According to A. O. Shobo, of Lever Brothers, Nigeria, however, the situation is slowly changing. While it used to be the case that all R & D problems were referred to headquarters for solution, there is now a gradual recognition that there is a limit to the scope of R & D that can be carried out without an adequate knowledge of local conditions. Local companies are gradually setting up their own R & D activities.

The majority of scientists in Nigeria are in the universities. They have a major role to play in developing local industry based on local raw materials and appropriate technology. But they face many difficulties, the main one being financial. To study a problem until the results are applied in industry requires continual and intimate collaboration between industry and the university which few local enterprises can afford. It is easier to buy imported processes even where this means importing preprocessed raw materials or intermediates.

0028-0836/79/0277—0168$01.00

Ekong suggested solving this problem by compelling all industrial enterprises in Nigeria to contribute to a fund for local industrial R & D. They would be able to claim rebates depending on how much they spent on local R & D. He also suggested that tax incentives be given to industries based on local knowledge and raw materials.

Ekong believes that without significant input from the universities there will be no self-sustained growth in industrialisation in the foreseeable future. However, because governments regard research facilities as luxuries developing countries can ill afford, "most chemical laboratories in our universities are ill-equipped and lack basic facilities for even the most elementary research", says Ekong. "Lack of scientific leadership is the principal reason for the low scientific output and is an area where international collaboration could be fruitful. Dr C. C. Mjojo from Chancellor College, Malawi, pointed out that there was little difficulty in finding money for applied research but support was needed for the pure natural sciences.

Lynette Hamblin

Lynette Hamblin is editor of Education in Chemistry

Grain production in Pakistan. Top left: terraced farming. Above: grinding wheat.

Pakistan reorganises agricultural research after harvest disaster

AFTER a disastrous wheat harvest in Pakistan last year (the shortfall in expected production was 1 million tons), the Pakistani government has had to import 2.2 million tons of wheat at a cost of 4,000 million Rupees ($400 million). The bad crop came as a particularly hard blow because the country had hoped to achieve self-sufficiency in food last year and wheat is its staple food.

The poor crop can be attributed to the fact that 75% of the wheat was afflicted by rust. The main reason for such widespread infection seems to be due to the fact that the popular commercial wheat varieties used had not been bred for rust resistance.

The Pakistani government lays the blame with its agricultural policy and the way in which the country goes about agricultural research. There are agricultural research institutes in Pakistan but most of them are isolated in the provinces and suffer from a lack of central coordination. Most of their research on breeding has centred on improving yields. Breeding resistance to adverse conditions such as disease or weather has been largely overlooked. And many very important aspects of agricultural research such as climatology, plant biology, agronomy and pathology are barely covered at all.

Dr Amir Mohammad, chairman of the Agricultural Research Council in Karachi has plans to improve Pakistan's agricultural research. The ARC has already drawn up the following measures for quick implementation:

- The creation of a National Agricultural Research Centre. This is already being built in Islambad on 1,300 acres of land. It is planned as a centre of excellence for agricultural research and is being funded by Pakistan and to the tune of $19 million by foreign grants and loans.

  The centre will consist of institutes on agricultural climatology, plant biology, agricultural data and planning, agricultural engineering and machinery, forestry, fisheries, water-shed management, arid-zone research, rural sociology, and a national plan introduction centre. Building should start in mid-1979 and the centre should be functioning in about three years time.
- The creation of a National Commodity Institute under the ARC. This will conduct research into individual crops and livestock. It will consist of separate sections for each major crop, such as wheat, rice, sugarcane, and cotton and a livestock section. Existing provincial research institutes will remain but will be under the NCI and the NARC.
- Manning of the institutes. 150 first-rate scientists will be needed. Pakistan is short of such manpower, so it plans to put new graduates into a six-month training course and then to send most of them for further training abroad.
- The division of the country into eight agro-ecological zones each carrying a different climate and ecology. An advisory committee of scientists and local farmers for each particular zone, will meet periodically to assess local conditions and recommend measures for ensuring optimum output.
- Strengthening of the small cereal Diseases Research Institute operating under the ARC so that it can incorporate studies of new cereal pathogens and screen new cereal strains for resistance to various rusts.
- The development of a coordinated research programme. ARC plans to have a strong research group on the socio-economic aspects of agriculture, which will also deal with large and small-scale planning of the country's agricultural resources.

At a Wheat Research and Production Seminar held in Inslambad last August, Dr Norman Borlaug, Director of CIMMYT, Mexico, expressed the view that Pakistan could increase its wheat production from 8–9 million tons to 15 million tons if farm production was made more efficient. At present, in spite of the 'Green Revolution', the wheat yield in Pakistan is quite low. As against Mexico's 4,175 kg/Hectare, Egypt's 3,343, and the US's 2,022, wheat production in Pakistan is only 1,411 kg/Hectare.

The Piltdown hoax

SIR,—Halstead's preliminary presentation of allegedly new material on the Piltdown hoax[1] could not reasonably be expected to encompass all the evidence which has accumulated in relation to anthropology's most notorious forgery. Nonetheless, one might have hoped that the tape-recorded allegations of the late Professor Douglas would have been accorded a tolerably critical analysis. Such is not the case.

Douglas and Halstead's attempt to implicate Sollas (and Dawson), whilst it may appear plausible to the casual reader, at best represents only a small part of the truth about Piltdown, and at worst depends upon exaggerations and imprecisions. Let me give some examples.

Although Halstead does not qualify Douglas' assertions about Dawson's reputation, they are in fact grossly misleading. Whether or not Dawson was guilty of Piltdown, he certainly did not acquire a reputation for perpetrating hoaxes during his lifetime. In fact he was a respected collector of fossils and antiquities for the British Museum. To be sure, after the exposure of the Piltdown forgery in 1953, a number of insinuations against Dawson's integrity were assembled,[2] and it has recently been shown that some Roman brick-stamps which Dawson donated to the British and Lewes Museums are forgeries.[3] However in the first instance the insinuations may represent retrospective mud-slinging by local Sussex antiquaries jealous of the international fame which Dawson achieved through Piltdown, and in the second instance the possibility remains that Dawson was the dupe rather than the forger. Certainly prior to his death in 1916, there was not a hint of scandal about Dawson. Even in relation to Piltdown itself, Dawson's guilt is far from proven. Of the three full-length books written about Piltdown after 1953, two argue that Dawson was innocent,[4] and the third, while implying Dawson's probable guilt, pointedly avoids expressing its final conclusion in positive form.[5]

Apart from glaring inaccuracies such as the above, the Douglas/Halstead hypothesis embodies many statements which are so vague as to be practically worthless as evidence. The potentially crucial assertions that Sollas knew and visited Dawson, that Sollas received a packet of potassium bichromate, and Sollas borrowed some ape's teeth, are left with no firm indications as to when these events allegedly occurred. If they took place after December 1912, their occurrence would almost certainly be irrelevant to the hoax. Even the incident of the Sherborne Horse's Head, which constitutes the most suggestive part of the Douglas/Halstead case, is open to many interpretations.

Certainly a Sollas/Dawson conspiracy would provide a possible, perhaps even a likely, explanation for the Piltdown hoax, but the best evidence for such a conspiracy lies in areas untrodden by Douglas and Halstead. The 1911 edition of Sollas' *Ancient Hunters* provides a detailed description of "Heidelberg man", an earlier candidate for the title of "missing link" which probably served as a model for Piltdown, and which is known to have preoccupied Dawson circa 1912. Moreover, since the Piltdown forger chemically treated the cranial fragments in an attempt to make them appear fossilised,[6] it is surely worth noting that Sollas had done important pioneering work on the chemistry of fossilisation,[7] work which Dawson may well have utilised in interpreting the Piltdown remains.[8]

However, because of problems surrounding Sollas' motivations, problems which Halstead's communication fails to resolve, I am inclined to lay the blame for Piltdown elsewhere. My current working hypothesis is that Elliot Smith instigated the hoax, and that Smith Woodward may have been a willing accomplice. This hypothesis does much to illuminate a formerly puzzling episode from Australian prehistory, an episode in which, incidentally, Sollas played a supporting role.[9]

Allies against Lysenko

SIR,—In Vera Rich's moving account of Professor Lev Tumerman's seven years in solitary confinement (14 December, page 662), she mentions that he recalls "one very good book by Sunnot and Dent". He no doubt meant to refer to the classical textbook of genetics by Sinnott, E. W. and Dunn, L. C. *Principles of Genetics*, McGraw-Hill, New York and London, 1925 which went through several editions (the last with Dobzhansky) and which for almost four decades (1925–1965) was the standard text in this field. E. W. Sinnott was professor of botany at Columbia and then Yale and L. C. Dunn was professor of zoology at Columbia. Dunn, who died in 1974, was active in the field of developmental genetics for more than a half-century; a fascinating review of his life and work has appeared recently (Bennett, D. *Ann. Rev. Genet.* **11**, 1–12; 1977).

It is interesting that Dunn, who was often bitterly attacked in the United States for his devotion to what were at that time left-wing causes, was an outspoken critic of Lysenko and of the Soviet persecution of their geneticists and of other scientists and intellectuals, such as Tumerman himself.

Who assesses risk?

SIR,—I was much struck with Wendy Barnaby's report of the Swedish seminar on risk assessment (7 December, page 554). The impression conveyed was that informed and impartial politicians ought to regard a democratic society's evaluation of risk perception as even more important than quantified objective risk. This is tantamount to saying that it is more important to consider the number of people who would be frightened than the number of people who would be killed.

The conclusion is that one should favour energy production from fossil fuels which kill far more people, rather than nuclear power which frightens far more people.

I can see why short-sighted politicians might approve this view, assuming that the fears of the public will last at least until the next election. Dead people don't have votes. Frightened people do. But I am surprised that *Nature* appears to approve the same opinion.

Not by force of ARMS

SIR,—I welcome the article by Joe Schwartz (23 November, page 310), drawing attention to the unsatisfactory job security and career prospects of research staff. Technicians and graduate research assistants, as well as post-docs, are often victims of short term contracts.

May I underline the point that it is the quality and strength of local trade union organisation which determines how effectively these issues can be negotiated with each university, medical school, college or institute. For this reason I was alarmed by the suggestion that ARMS "intends to negotiate with employers". Indeed, I am sure it would delight these employers to be relieved of the embarrassing task of trying to justify their practices to the experienced negotiators of strong trade union organisations. I welcome ARMS to the extent that its existence demonstrates the concern felt by research staff, but I must qualify this by warning that the ARMS could backfire if it diverts staff from the need to work within trade unions.

Finally, I should clarify that I am not a "division organiser" for ASTMS (as reported in your article). I am one of many lay activists within ASTMS who have been tackling these issues, and many others, for some years.

PHILIP HOUNSELL

London, UK.

Quaternary correlations

from D. Q. Bowen

For the foreseeable future the major challenge confronting Quaternary research must be correlation of the oceanic and continental records. Continental models of Quaternary history are now inadequate and already a re-evaluation has commenced. Astonishingly this has been long delayed, for the implication of such inadequacy, and of greater complexity was plain for all to see from Emiliani's work on stable isotopes from deep sea cores during the early 1950s. Partly the delay was due to misconceived interpretation of the oceanic evidence in the light of continental models, whereas now, despite some lingering opposition, the horse has at last been placed firmly in front of the cart.

Notwithstanding the eminently reasonable geological suspicion of notions of continuous sedimentation, the open ocean (pelagic) environment constitutes a special case. There sedimentation by settling through the ocean takes place more or less constantly for long periods as demonstrated by inter-core correlation throughout the world's oceans based on repetitive isotopic signature, palaeomagnetic character, assemblage faunal analysis and, increasingly, by the extinction of certain taxons at isochronous levels.

The oceanic oxygen isotope stratigraphic framework shows the changing isotopic composition of the world's oceans throughout the Quaternary. Preferential evaporation of the lighter ^{16}O and its incorporation into ice sheets on the continents tends to enrich the oceans residually in ^{18}O during glacials. Conversely during interglacials isotopically lighter water is returned to the oceans. Foraminifera from deep sea cores, which precipitated their calcareous tests in isotopic equilibrium with the water they inhabited, monitor such changes, and allow definition of oxygen isotope stages numbered backwards in time, using odd numbers for interglacials and even ones for glacials. This stratigraphic framework records changing ice volumes on the continents, and by inference the changing climate also. It shows that during the 1.6 Ma of the Quaternary some 18 glacials occurred which compares with the celebrated four-fold glaciation model of the Alps. This has dominated thinking for so long although it only represents the last 850 ka during which time 10 actual glacials occurred. The extent to which the Alpine model influenced others and the terms on which new data were collected and evaluated in terms of a four-fold sequence, is only now becoming apparent with the realisation that much of the primary data base in terms of basic field geology is inadequately known in many areas.

Without geochronometric control, for example ^{14}C, uranium series and K/Ar, traditional means of correlation continue by plotting data graphically to show fluctuations of climate through time. Correlation is principally by tele-correlation relying on curve-matching assisted occasionally by radiometric tags at crucial points. Hitherto the best results, which bear an amazing resemblance to the oceanic record, come from the loess terrains of central Europe (with signs that work on the loess of China is not far behind). There, sequences of loess, palaeosols and other indicator deposits, coupled with the recognition of palaeomagnetic reversals for dating, allow correlation back to the beginning of the Pleistocene. Other key localities include the long lake sequences of the Vosges, Macedonia, Colombia, Queensland and Japan, where climatic variations are recognised from pollen analysis. Such a technique is eminently successful when applied to continuous layers of sediment, but rather less so when the data are fragmentary and stratigraphic succession inferred by an additive process using geographically widespread data. One pollen sequence may look much like another for the fact is that repeated constellations of species re-appeared during successive similar climatic episodes, perhaps with different emphasis in the relative timing of arrivals, but as the regional variation of the vegetation is largely unknown this cannot be used for definitive dating. For Northern Europe it was formerly thought that the interglacials of the Middle and Upper Pleistocene were known and sufficiently well differentiated—Cromerian, Holsteinian and Eemian. However, in the light of the oceanic evidence, there must be at least six interglacials. Clearly the problems are beyond the resolving power of the method, which is not surprising since it relies not on first appearances nor extinctions, but on assemblage floras, a biofacies basis which is inherently unreliable on account of its diachronous nature.

Using this method marine deposits from Western Norway are correlated with the Eemian Interglacial and also with oxygen isotope stage 5e (Mangerud *et al.*, this issue of *Nature* page 189). In equating Eeemian with stage 5e the authors follow Shackleton (*Proc. Roy. Soc. Lond.* **B.174**, 135; 1969) and there can be little doubt that the Last Interglacial at 125 ka is a prominent feature of sequences throughout the world. The chrono-

Oxygen isotope stage	Classical continental stages		
1	'Holocene' (postglacial)		
2			
3	Weichselian (last glaciation)		
4			
5a-5d			
5e	'Eemian' (of Schleswig-Holstein)	Eemian sl	Saale sl
6	Warthe		
7	'Eemian' (northern Germany)		
8	Reburgh		
9	'Eemian' (Amersfoort)		
10	Saale ss

0028-0836/79/0277—0171$01.00

stratigraphic term Eemian, however, is potentially misleading, for Kukla makes a compelling case for the recognition of three stratigraphically separate Eemian Interglacials (*Earth Sci. Rev.* **13,** 307; 1977). The type Eemian, considered by the authors, is near Amersfoort in the northern Netherlands. It lies between Saale glacial deposits and sands of the Last (Weichselian) Glaciation (isotope stages 2, 3, 4 and 5a–5d). Kukla argues that three glaciations occurred during the period traditionally referred to as Saalian (Saale(ss), Rehburg and Warthe), and that the Saale (ss) corresponds to oxygen isotope stage 10. Thus because the Amersfoort Eemian deposits appear to be continuous with the underlying Saale(ss) they should be correlated with stage 9. Eemian of isotope stage 5e is probably represented by the interglacial deposits of Schleswig-Holstein where marine beds clearly overlie and breach end-moraines of the Warthe Glaciation (isotope stage 6). Clearer stratigraphic demonstration of two Eemian Interglacials (probably corresponding to stages 5e and 7) is found in Northern Germany where they are separated by glacial deposits (Wiegank, *Geologie* (*Berlin*) **21,** *Beih.* **77,** 1; 1972).

Correlation of the Norwegian deposits with the type Eemian (stage 9?), on floristic grounds, and also with stage 5e, is, therefore, not unequivocal. It may be that correlation with the Eemian of Schleswig-Holstein (5e?), is sounder, because faunal evidence from the Norwegian deposits, showing higher temperatures than today, matches stage 5e from deep sea cores in the Norwegian Sea. Such a correlation is not as tenuous as might appear for comparable temperatures have only been recorded twice in the last 450 ka.

The problem of 'Eemian', and other similar terms, remains, and is symptomatic of the state of continental frameworks at the present time. These require urgent revision and redefinition in the way Kukla has attempted for Europe. It may mean a plethora of new stage terminology, often on a local if temporary basis, but until the basic ground is secured in this way progress will be hindered. The existing continental frameworks cannot continue to bear the brunt of attempted correlation with oceanic or other records either for the specialist or numerous users of Quaternary data. ☐

Bacteriophage assembly

from Roger W. Hendrix

Any recent textbook of cell biology or biochemistry contains a diagram based on the experiments of Edgar and Wood that outlines the assembly of bacteriophage T4. In the best tradition of Henry Ford, protein and DNA molecules assemble sequentially into the component parts (heads, tails, tail fibres), and these subassemblies then join each other to form the finished product, the virion. This scheme of phage assembly has been incorporated into biochemical lore, widely quoted, sometimes overinterpreted, and not infrequently taken to represent a relatively complete understanding of virus assembly. However, despite the elegance and importance of Edgar and Wood's original experiments, basic questions are still unanswered, and phage assembly remains a fertile field for investigation into the principles of biological form determination. Some of the highlights of recent work in the field were aired last September at the Sixth Biennial Conference on Bacteriophage Assembly.

Forming the intellectual backdrop to the meeting were a number of major conceptual advances in understanding virus assembly that have developed over the past decade. Some of these are the following. Assembly pathways are in general quite strictly ordered and, although all of the relevant proteins are present together in the cell, they associate with each other only when the pathway requires it. In other words, the order of assembly is regulated by the assembly pathway itself rather than, for example, by the order of transcription or translation. Virus assembly, at least in the case of the structurally elaborate phages, is more than a simple 'self-assembly' process in which all of the information for assembly resides in the components present in the final assembled product. Although many individual steps in the assembly of these viruses undoubtedly involve true self assembly, other steps in the process require the intervention of proteins that act as assembly tools or catalysts and are not themselves found in the completed virion. Among the 'tools' that are beginning to be characterised ~~are~~ proteins that form transient scaffolds which direct the assembly of other proteins, and enzymes that cause covalent alterations of proteins already assembled. The actual DNA packaging event has been a central issue for many years, and it has become clear that DNA is condensed into a preformed protein shell—this in contrast to the original idea that the DNA first condenses and is then surrounded by protein.

Several of the 50 papers presented in Toronto dealt with the question of size determination. That is, how is it that virus substructures such as heads and tails are virtually always the right size, even though their component proteins can frequently be shown *in vitro* or in mutants to be capable of forming structures of a variety of different sizes? An interesting case is found in *Escherichia coli* phages P2 and P4. P2 by itself makes uniform sized heads. However, if a cell is coinfected with P2 and P4 (a satellite phage which itself codes for no head protein) then the P2 head proteins are assembled into smaller P4-sized heads. Assembly of P2 proteins into P4 heads is directed by a P4 gene that has been named *sid* (*s*ize *d*irection). J. Geisselsoder, M. Chidambaram, and R. Goldstein (Harvard University) presented evidence that the *sid* gene influences the efficiency of transcription termination on the P2 genome. They proposed that in the presence of the sid^+ gene product the relative amounts of certain P2 head proteins are altered, and that it is these crucial ratios that determine the size of the head assembled from the head proteins.

In the case of size determination of T4 heads, interest centred on the well known fact that the head is elongated in one direction. Genetic studies reported by D. Doherty (University of Washington) show that mutations in the gene coding for the major head protein (gp23) which cause the production of non-elongated heads can be suppressed by simultaneous mutations in genes *22* and *24*. These genes code for the protein (gp22) of the scaffold around which gp23 assembles and the protein (gp24) that constitutes the corners of the head. The results suggest that the three proteins interact with each other to determine head length. L. Onorato and M. Showe (University of Basel) presented biochemical experiments which also implicate these three proteins in head length determination. Their experiments further suggest that the ratios among the concentrations of these proteins influence the size at which the growing shell is capped off; thus they arrive at a conclusion analogous to the results with P2 and P4 heads by a different experimental route. R. van Driel (University of Basel) described reconstitution experiments with purified proteins which showed that the scaffold protein (gp22) will assemble in the presence of an initiator protein (gp20) into what appear to be normal

---

Roger Hendrix is Associate Professor of Biological Sciences at the University of Pittsburgh.

sized scaffolds. This argues that at some level the scaffold protein 'knows' the correct head length even in the absence of gp23 and gp24.

The mechanism of DNA packaging has been a favourite problem in the field, and there has been impressive progress in recent years, particularly since it has become possible to package DNA *in vitro*. The papers on DNA packaging in Toronto ranged over a wide variety of topics including how the DNA is recognised by phage proteins, how it is cut to its mature form, and the relation between cutting and packaging. One particularly interesting report for this field which has primarily been concerned with packaging double-stranded DNA, was a paper by K. Koths and D. Dressler of Harvard University on packaging the single-stranded DNA of φX174. Their evidence shows that the preformed protein capsid is associated with the replicating DNA, apparently as part of a complex at the replication fork of a rolling circle, where it takes up the DNA as it is made. Replication and packaging of DNA are tightly coupled in this case, and it is tempting to speculate that the driving force for packaging might be derived from replication. This is in marked contrast to the case of double-stranded phages where replication and packaging are clearly separable.

Two models were presented for how DNA is moved into the heads of double-stranded DNA phages (L. Black, University of Maryland; R. Hendrix, University of Pittsburgh). These, if nothing else, reflect the current state of experimental evidence on the problem, they both differ from previous models in postulating that the force that drives the DNA into the head is applied by a small proteinaceous machine that sits in the head shell at the point where DNA enters (thought to be the point at which the tail later attaches).

The most stimulating paper at the meeting, to my taste, was one by J. Shaw and H. Murialdo (University of Toronto) which admits phage lambda to the club of viruses with overlapping genes. They find that the lambda head gene *Nu3* is contained within the last one-third of the *C* gene. The two corresponding proteins, gpNu3 and gpC, are read in the same phase and presumably use the same translational termination signal (that is gpNu3 is identical to the C-terminal one-third of gpC). The real interest in these results probably lies not in the fact that they give yet another example of overlapping genes but in the fact that it may be relatively easy to decipher the functional significance of the overlap. gpC is most probably part of the head initiation complex on to which the scaffold protein gpNu3 assembles, and it is easy to imagine models in which the C-terminal portion of gpC might serve, for example, to nucleate the assembly of the gpNu3 scaffold.

Much of the research in phage assembly in past years has dealt with working out pathways, measuring compositions of intermediate structures, and otherwise defining the outlines of assembly processes. It was evident in Toronto that the emphasis is now moving toward more detailed mechanistic questions at the level of how proteins and parts of proteins interact with each other and with nucleic acids. For example, two elegant structural studies addressed the question of how the protein subunits of the head shell change their conformation as the shell expands during DNA entry. S. Casjens (University of Utah) used freeze-etch electron microscopy to argue that the major head shell protein, gp5, of P22 consists of two domains and proposed that head expansion could be accomplished by the flexing of a hinge connecting the two. A group from the University of Basel (U. Aebi, R. van der Broek, P. R. Smith, B. ten Heggeler, J. Dubochet, V. Mesyanzhinov) examined the analogous lattice expansion in T4. By using electron microscopic image processing techniques and antibody fragments, they were able to visualise a specific antigenic site on the T4 major head protein gp23. They found, surprisingly, that on lattice expansion this site moves from the inside to the outside surface of the head.

The Toronto meeting was noteworthy for the consistently high quality of the papers, most of which have necessarily been skipped over in this report. It was particularly gratifying to see that for a number of the interesting problems of phage assembly there is now a large body of information from each of several phages. This has made it possible to begin to decide which features of a given assembly process are fundamental and which are variations on a theme. The general impression was that the groundwork for understanding assembly of phages has been solidly laid and that future work will be progressively more concerned with problems that can be generalised to other biological systems.

Muons and muon trapping by solid-state imperfections

from A. M. Stoneham

THE positive muon has an obvious potential in solid state physics. Its spin polarisation can be monitored to give data such as the site it occupies, local magnetic fields, diffusion rates and Knight shifts. If a suitable beam is available from a meson 'factory', the experiments themselves do not need especially sophisticated equipment. So it is not surprising that the μSR field is very active (see *News & Views* **276**, 324; 1978) both in an attempt to understand the way muons behave in solids and to exploit muons to understand better the solids in which they decay.

Several groups have found evidence that muons can probe defect and impurity properties in metals. Since the defects include deformation-induced dislocations and damage from neutron irradiation, and since the impurities include both alloying metals and trace impurities like oxygen, the muon promises to be a very versatile tool. Many gaps remain. To understand these, one must look at the principal processes involved. The first is the slowing-down process in which the muon comes to rest. Usually the muon will end in an interstitial site, self-trapped by the lattice distortion it causes, and vibrating like any normal chemical impurity. The second process is diffusion. Presumably this is described by the quantum theory developed for light interstitials by Flynn and Stoneham; the features of importance here are that the rate should increase with temperature, as a power law at low temperatures and thermally-activated at higher temperatures. One might expect μ^+ diffusion to resemble diffusion of H^+, D^+ or T^+, with a suitable isotope effect, though present data are too limited to check in detail. The third process is defect trapping, due to the strain fields of imperfections or to their perturbation of the electronic structure. At high temperatures, release from traps occurs. There is also a fourth process, independent of the solid: the muon decays with a characteristic time of 2.2 μs, and this imposes limits.

If there is only a single type of trap, one can outline the way the depolarisation rate should vary with temperature. Four main regimes are expected. In regime I, at the lowest temperatures, the muon does not diffuse significantly; it merely comes to rest, and measures an average property of the solid. In II

Primaeval magnetic monopoles

from P. C. W. Davies

One of those curious apparent imperfections of nature is the lopsidedness of electricity and magnetism. The world abounds with electric particles (all atoms are made of them) but nobody has ever seen a pure magnetic particle Magnetic fields can, it seems, only be produced by moving electricity, that is, electric currents Consequently, when magnetism occurs, magnetic charge always appears in tandem (north and south), never singly Tandem charges are called dipoles and single charges, if they exist, are known as monopoles. Matter is built out of subatomic electric monopoles, but magnetic monopoles elude us. This is all the more surprising because of the celebrated mathematical symmetry built into our theory of electromagnetism.

The great nineteenth century physicist James Clerk Maxwell unified electric and magnetic fields, and discovered the principles which govern their interplay, but his beautiful theory is marred by the asymmetry of the monopoles. In the 1930s Paul Dirac gave an argument, subsequently developed by Julian Schwinger, that if magnetic monopoles exist they will have magnetic charge only in fixed multiples of a fundamental unit, simply related to the fundamental unit of electric charge, such as we find on the electron A few years ago the Soviet and Dutch physicists A. M. Polyakov and G 't Hooft argued that magnetic monopoles could exist on subatomic particles with masses in excess of five thousand proton masses.

There has always been room in theory for magnetic monopoles, but elaborate searches among ordinary matter have persistently failed to detect any. Despite a recent flurry of excitement that one had been found in cosmic ray debris, the monopole remains perhaps the most significant non-discovery of the century.

Sometimes negative evidence can be useful in revealing information about other physical systems. The non-detection of quarks, for example, has been used as a motivation for theories of subatomic particle structure In a recent paper (*Phys Lett.* **79**B, 239; 1978) the Soviet mathematical physicist and astronomer Ya. B. Zeldovich, and a colleague at the Institute of Applied Mathematics in Moscow, M. Yu. Khlopov, have argued that the experimental absence of magnetic monopoles raises serious doubts either about their existence or the popular understanding of the origin of the Universe. The central idea is the theory that the Universe began with an intensely hot big bang. Indeed, so energetic was this event that we can be sure that any subatomic particles that can exist would have existed at sufficiently early moments (that is, sufficiently high temperatures) And this includes magnetic monopoles, despite their predicted enormous masses

Zeldovich and Khlopov calculate that inside the first 2×10^{-11}s the monopoles would have been in thermodynamic equilibrium at a certain concentration among all the other matter, but that as the explosive expansion rapidly cooled the primaeval cosmological material, the temperature fell too low to sustain the monopoles, and they started to annihilate each other. The annihilation is a consequence of fundamental physics that a magnetic north pole is the antimatter image of a south pole, and close encounters between them result in mutual destruction.

In the subsequent phases of the expanding fireball, most of the monopoles would have disappeared as a result of this mechanism But not all. Merely on statistical grounds some monopoles would have avoided their opposite numbers and escaped this demise. This is because both the density of matter, hence monopoles, was falling rapidly, and the temperature, hence speed, of subatomic particles also plummeted. The authors calculate the residue of relic monopoles coughed out of the big bang which should still exist. The annihilation ceases after about 10 ms, leaving a total concentration today of around 4×10^{-19} cm^{-3}, or less than one monopole per million million atoms Small though this is, it is enormously greater than the experimental upper limits already set ($10^{-19}-10^{-28}$ cm^{-3}) from examination of lunar and terrestrial matter, and cosmic ray studies.

There seem to be two alternative explanations of this inconsistency. One is that nature truly is lopsided, and that magnetic monopoles simply do not exist in isolation (There is still the possibility that for some obscure reason monopoles exist in permanently confined multiplets, like quarks) The second is that the standard hot big bang model of the Universe is badly wrong, at least in some of its details We thus have an additional motivation for seeking out monopoles, for their discovery as free particles would, unless the previous abundance estimates are a fluke, tell us much about the first micromicrosecond of the Universe.

One of the ironies about papers of this type concerns the central role played by aesthetics Belief in magnetic monopoles stems primarily from a deep-rooted desire that nature should be elegant and symmetrical. Similarly in cosmology, sweeping assumptions are made about the structure of the primaeval Universe which, once again, stem from the yearning for simplicity Now we see that cosmic simplicity (primaeval thermodynamic equilibrium) and subatomic symmetry are in conflict The resolution cannot be found by aesthetics alone. Only experiment can decide which assumption is wrong

P. C. W. Davies is in the Department of Mathematics, King's College, London.

---

the muon diffuses faster and faster as the temperature rises, and the rate at which it samples different internal magnetic fields affects the depolarisation rate and can be measured. This regime ends at a temperature fixed by the trap density, and in region III, the muon monitors properties of the trapping site. Finally, in region IV, release from traps and motional-narrowing occur Obviously, behaviour gets more complicated when several distinct traps are involved, but the principles are the same. Many workers have obtained results fitting this qualitative description of the temperature dependence.

For this picture to be useful, it is important that the muon can indeed diffuse to the traps of interest. The muon lifetime sets a limit here. In most metals studied (V, Nb, Ta, Cu, Fe) at accessible temperatures the muon hopping time between diffusive jumps is in the range 10^{-8}–10^{-7} s corresponding to a mere 0.2 to 20 jumps in a lifetime. Diffusion from a random stopping site to any trap present in low concentration is negligible. And indeed the irradiation of Cu and the doping of Nb by Ta have little observable effect on muon properties Two metals are different, and appear to show very fast diffusion : Cr, with a hopping time around 10^{-11} s and Al, where motional narrowing appears to be complete even at the lowest temperatures, with times such as 10^{-10} s at 10 K and 10^{-12} s at 50 K indicated.

Several groups have studied trapping

0028–0836/79/0277—0174$01.00

in Al, including workers at laboratories in America, Sweden and Germany. Two results are particularly interesting. One was reported by Seeger at a recent Rutherford Laboratory meeting, and is from Stuttgart workers, who looked at neutron-irradiated Al. The point here is that the basic defects, and hence the traps, can be modified by annealing. Reversible changes with temperature reflect the muon motion, whereas irreversible ones indicate changes in defect structure and can be related to previous damage work. Two traps were detected in Al : one was shallow, possibly an interstitial cluster; the other trap was deeper and is not yet identified. The second result comes from a collaboration among five of the American laboratories (*Phys. Rev. Lett.* **41,** 1558; 1978). The experiments showed the effects of Cu impurity and of deformation. The dislocations act as deep traps, with a binding of around 0.2 eV, and also seem to show the rapid pipe diffusion known from conventional diffusion studies. The Cu appears to give rise to some four different shallow traps (binding the muon by less than 1/50 eV) even at the low concentrations used (420 and 1,300 p.p.m.). The authors argue these traps are microclusters of Cu, and that the clusters are present at levels far above random. If so, the muon technique is giving new information about alloy structure in circumstances hard to match otherwise.

What then are the prospects? If the interpretations are right, muon spin resonance adds another tool to the study of alloy structure, complementary to positron annihilation, neutron scattering and various forms of electron microscopy. Clearly muon experiments need a large accelerator, and cannot be as portable as techniques like positron annihilation; applications to macroscopic defect structure, as in nondestructive testing, will have to be reserved for special cases. There are also some open questions. Are there really so many microclusters in Al:Cu? Are there systems where such muon results can be checked by other methods, like magnetic or Mössbauer techniques? If these microclusters are real, do they affect mechanical properties? Another question is in how many systems can the muon probe defects and impurities? Diffusion rates mentioned earlier suggested that the success with Al was the exception, not the rule. This need not be so. Slow diffusion only prevents the muon probing a trap if the stopping site is random within the crystal. However, a slowly-moving muon may be stopped preferentially near defects, by its interaction with their strain field or otherwise. This may be why results on vanadium are very sensitive to interstitial oxygen. In such cases the muon will probe the defects, but will give little information about the perfect host. Non-metals present their own special problems. Ionisation-enhanced diffusion in semiconductors may ensure the muon can always reach a defect; recombination-produced vacancies and interstitials in ionic crystals may ensure there are always defects to be reached. All in all, the exploitation of muons promises to yield scientific problems as well as solving materials ones. ☐

A hundred years ago

INVALIDS will be glad to learn that, amidst the severe weather, a comparatively mild climate exists in a part of their own country. A bouquet arrived from Glengariff on Saturday, the 11th instant, comprising wallflower, primrose, primula, stocks, chrysanthemum, scarlet geranium, arbutus-berries, and a rose-bud, all picked from an exposed garden. In Madeira—but five days' journey—ripe bananas and custard-apples are hanging on the trees. Many of the gayest flowers are in full bloom.

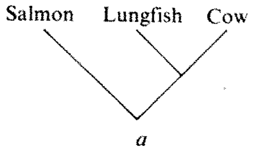
The salmon, the lungfish and the cow: a reply

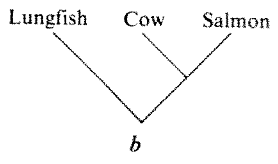
THE debate on cladism has smouldered in specialist journals for over a decade, and we are glad that Halstead has brought it to *Nature* (*News & Views* **276,** 759; 1978). An adverse review (Cain *Nature* **216,** 412; 1967) of Hennig's book (*Phylogenetic Systematics* University of Illinois Press, 1966) is about the only previous sign of the controversy in this journal. As participants in the meeting at Reading, named in Halstead's report, we find his account seriously defective in two respects—as a description of the meeting, and as a summary of the claims of cladism and the history of the controversy.

On cladism in general, Halstead's report reveals several assertions and misunderstandings about aims and methods that were common in the early days of the controversy, and have been fully discussed in *Systematic Zoology* and other journals. Rather than repeat those arguments, we should like to focus on what is, in our view, the principal source of acrimony between cladists and evolutionary systematists, a problem neatly summed up in a question raised at the Reading meeting and reported by Halstead: 'according to the cladists a lungfish is more closely related to a cow than to a salmon'. Halstead correctly reports the exasperation with which the accusation was put, and the complacency with which one of us accepted it. If experienced comparative anatomists can disagree on so simple and fundamental a question, either there is revolution in the air, or words are being used in different ways.

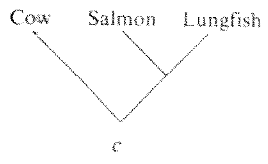
Given three taxa—for example, a lungfish, a salmon and a cow—a cladist will draw up the three cladograms showing the three possible 'more closely related' pairs.



a



b



c

Each of these concepts has its advocates, but at Reading, *a* was the preferred solution of the cladists, us included, and *c* was the preferred solution of Parrington and Halstead, whom we shall refer to as evolutionary systematists, following Mayr (*Z. Zool. Syst. Evolforsch.* **12,** 94; 1974). Since we do not believe that evolutionary taxonomists disagree with us over the characters of lungfish, salmon and cattle, the disagreement is evidently over the meaning of the concept 'relationship'. Although 'relationship', 'affinity' and cognate words have been freely used in the evolutionary and pre-evolutionary literature of biology, Hennig was the first, to our knowledge, to give an unambiguous definition of the concept. Mayr (*op. cit.*) summarised Hennig's definition of relationship; 'the measure of phylogenetic relationship is the relative recency of common ancestry'. Stung to give precision to a concept they had previously used in various senses, evolutionary systematists seem to have settled on 'genes in common' as the measure of phylogenetic relationship (Mayr (*op. cit.*) 'inferred amount of shared genotype'). Ignorant as we are of the correspondence between the genotype and phenotype, and of the genotype in the vast majority of organisms, 'genes in common' is a rationalisation of 'characters in common', or overall similarity. Hence, when evolutionary systematists prefer cladogram *c*, they mean that lungfish and salmon are more similar than lungfish and cows. And in preferring cladogram *a*, cladists mean that they infer that lungfish and cows shared a more recent common ancestor than lungfish and salmon. This inference is drawn from the fact that lungfish and cows share derived characters (synapomorphies such as internal nostrils, an epiglottis, a two-chambered auricle and so on (*Kesteven Proc. Roy. Soc. Vict.* **59,** 93; 1951)) not found in salmon.

Given their reliance on overall similarity, it is not surprising that evolutionary systematists find that many of the groups they recognise are grades, nor that these grades 'happen to coincide with the major classes of the vertebrates' (Halstead *op. cit.*). Yet these vertebrate classes were recognised and named by pre-Darwinian systematists, who also used overall similarity as their guide, naturally enough. Overall similarity may be modernised or dignified by calling it 'genes in common' or 'shared genotype', yet when we do have access to comparative information on genes, as in globin sequences (Goodman *et al. Nature* **253,** 603; 1975; Romero-Herrera *et al. Nature* **261,** 162; 1976), the biochemists present their information in the form of cladograms, and use the same genealogical concept of relationship as Hennigians. Darwin (*Origin of Species*: see also Nelson *Syst. Zool.* **23,** 452; 1974) wrote 'our classifications will come to be, as far as they can be so made, genealogies; and will then truly give what may be called the plan of creation'. He might be surprised that after 120 years, some palaeontologists would be occupied with the defence of pre-Darwinian concepts and classifications.

Halstead's report contains many misunderstandings and ambiguities, a few of which cannot be allowed to pass unchallenged. It is not, as Halstead says of cladistics, "axiomatic that . . . sister groups are given identical ranks"; it is however a logical consequence if a formal classification is required. Nor does cladistics insist on a classification which reflects all of the ideas embodied in the cladogram. Cladists do not assemble characters subjectively into a hierarchy: though we suspect that the hierarchy of which Halstead speaks is a reference to character weighting, not favoured by cladists. Halstead also accuses cladists of belittling the significance of parallelism. But this is outside the scope of cladism since the recognition of such an evolutionary event presupposes that we already know the phylogenetic relationships of the organisms concerned.

Concerning Halstead's report of the meeting itself, we were surprised to read that papers delivered by two of us 'were demolished within hours'. Freedom of speech goes a little too far here, and we request that Halstead justify his assertion by saying who did the demolition work, and how it was done. Halstead charges us with 'religious fervour', but the charge might be reversed, for to us his statement that cladists 'are already entrenched in some of the major museums in the world' has an offensive taint of McCarthyism and the witch-hunt.

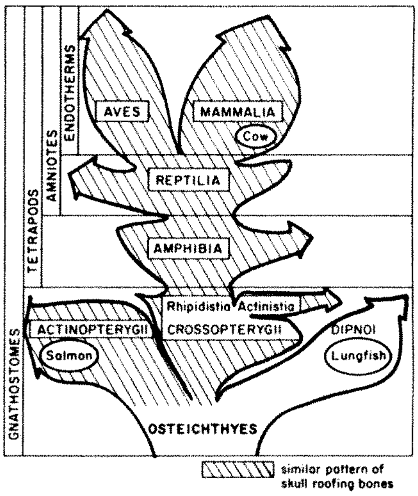
L. B. HALSTEAD AND COLLEAGUES REPLY: The mutual relations of salmon (an actinopterygian), lungfish (a dipnoan) and cow (a mammal, a class which can be traced back to rhipidistian crossopterygians by way of reptiles and amphibians) are certainly worthy of serious consideration. Gardiner *et al.* draw up "three cladograms showing three possible 'more closely related' pairs". Cladogram *a* is their preferred solution, but it is certainly not true to claim, as they do, that "*c* was the preferred solution of Parrington and Halstead". The cladists simply omit the possibility that none of the three pairings shared a more recent common ancestor, than any of the others, but rather were all derived from a pre-existing common stock, a view previously commended by Miles (*Palaeozoic Fishes,* 1971).

Assuming that cow, salmon and lungfish were derived from such a common ancestral stock, we would still insist that lungfish are closer to salmon on the grounds of neither having advanced significantly beyond the common heritage of all primary aquatic jawed vertebrates. In marked contrast, the cow is separated from both lungfish and salmon by several structural grades. The figure summarises these relationships.

At the meeting Gardiner presented a cladogram which purported to demonstrate that lungfish were more closely related to tetrapods than were either coelacanths or certain rhipidistian crossopterygians. The near structural identity of crossopterygians and early tetrapods makes it impossible for them to be separated by the uniquely specialised lungfish. Later in the meeting T. S. Westoll demolished this particular cladogram and pointed out that most of the features that Gardiner claimed were absent in coelacanths were in fact present in the material Westoll himself was studying.



Janvier's agnathan cladogram was a reflection of Stensiö's mistaken notion of the myxinoid affinities of the heterostracans, which has been discussed and firmly rejected by workers in the field (see *Biol. J. Linn. Soc.* **5,** 339–349, 1973; *Biol. Rev.* **48,** 279–332, 1973, for a summary of this issue).

The current Hennigian orthodoxy brings to mind the situation at the beginning of the present century. Then Haeckel's Biogenic Law and the attendant preoccupation with genealogies, had a stultifying influence on the whole of biology. 'When the results of a science are produced by methodological assumptions rather than by the evidence available, it is not science' as A. J. Cain remarked in his review of Hennig's book in *Nature.*

Cellular interactions in haematopoiesis

M. J. Cline & D. W. Golde

Division of Hematology-Oncology, Department of Medicine, University of California School of Medicine, Los Angeles, California 90024

In vitro *culture of haematopoietic cells has provided some surprising insights into critical interactions of blood-forming cells. Subpopulations of lymphoid cells have been shown to produce colony-stimulating activity, to interact with macrophages, and to have important effects on the very early stages of erythropoiesis. Macrophages have multiple influences on the proliferation and differentiation of other haematopoietic cells.*

PRIMITIVE pluripotent haematopoietic stem cells have the capacity to form all the blood elements, including myeloid cells, erythrocytes, and immunocytes[1]. In mice the stem cell for erythroid and myeloid lines is assayed by its ability to form haematopoietic spleen colonies in irradiated syngeneic recipients (hence, the stem cell is often called CFU-S, colony forming unit-spleen). The derivation of colonies from a single precursor cell was established by using a mouse with chromosome abnormalities as the cell donor. The same abnormalities were found in replicating cells of lymphoid tissues diffusely distributed in the spleens and lymph nodes of the recipient mice. Further evidence was derived by retransplantation of non-immunocompetent spleen colonies. Colonies developing in secondary host animals contained immunoglobulin-producing cells with the T6 chromosome marker of the original bone marrow donor. Direct evidence for a single stem cell common to the myeloid and lymphoid lines has recently come from reconstitution experiments in mice in which chromosome markers were induced in donor bone marrow cells by irradiation[2]. Myeloid spleen colonies and T and B lymphocytes in reconstituted animals had the chromosome marker of a common precursor. The appearance of the Philadelphia chromosome in cells of the granulocytic, mononuclear phagocytic, erythroid, and megakaryocytic lines of patients with chronic granulocytic leukaemia is evidence for the existence of pluripotent stem cells in man[3,4].

The process of commitment of pluripotent stem cells to one or another line of development is poorly understood. For example, the pluripotent stem cell is not responsive to erythropoietin but at some point in development it gives rise to an erythropoietin-responsive stem cell. Such a cell is unipotent and exclusively committed to maturation along the erythroid pathway. An analogous situation holds for granulopoiesis and responsiveness to colony-stimulating activity. In a certain sense, commitment may be defined as the acquisition of responsiveness to a specific haemopoietin. Under the influence of specific haemopoietins, there is further cellular proliferation and maturation until appropriate numbers of functional end-cells are produced. It is likely that in physiological circumstances most haematopoietic regulation occurs at the level of the committed stem cells. It has become apparent in the past few years that a diversity of cellular interactions can influence the formation of mature blood cells from stem cell precursors. The characterisation of these interactions had to await methodology for *in vitro* culture of haematopoietic cells. Of particular importance has been the development of a semi-solid gel culture system[5,6] for the growth of monocyte stem cells and of granulocytes (CFU-G,M). (In this review the term granulocyte is taken to mean neutrophilic granulocyte, although, strictly speaking, it encompasses neutrophilic, basophilic, and eosinophilic granulocytes.) With the subsequent development of *in vitro* techniques for assaying erythroid, megakaryocyte and eosinophil precursors and B and T lymphocytes[7], characterisation of the haematopoietic hormones which influence proliferation and differentiation has become possible. More recently, these techniques have been used to explore cellular interactions of combinations of purified cell populations or of the products of one cell lineage with the responsive cells of another lineage. Undoubtedly, some of the interactions reflect the requirements for cell growth under *in vitro* conditions; but others have physiological relevance.

Three major categories of cellular interactions have been defined thus far: the interaction between mononuclear phagocytes and a variety of other haemic cells; the interaction of T lymphocytes with progenitors of granulocytes, mononuclear phagocytes, erythroid cells, and eosinophils; and the cellular interactions of the stromal cells of haematopoietic organs.

Production of phagocytic cells

The principal phagocytic cells are the mature neutrophilic granulocytes and mononuclear phagocytes including monocytes and macrophages. The production of neutrophils is regulated by homeostatic mechanisms that normally maintain the numbers of

0028-0836/79/0277—0177$01 00

circulating cells within a narrowly defined range. The average neutrophil production rate for man is estimated at 1.6 × 10^9 cells per kg per day. Despite rapid turnover rate and high production volume, the neutrophil production system retains great flexibility in its response to inflammatory stimuli.

The production of neutrophilic granulocytes and mononuclear phagocytes are thought to be closely linked processes; both arise from a common precursor which forms colonies *in vitro* only in the presence of the haematopoietic factor, colony-stimulating activity (CSA)[8,9]. Increasing evidence suggests that CSA is also an important controlling factor *in vivo*[10]. Differentiation along one of the alternative cell pathways may be controlled by the type of CSA or its concentration. Furthermore, there seems to be a family of related glycoproteins with CSA activity, some of which have specificity for different target cells[11].

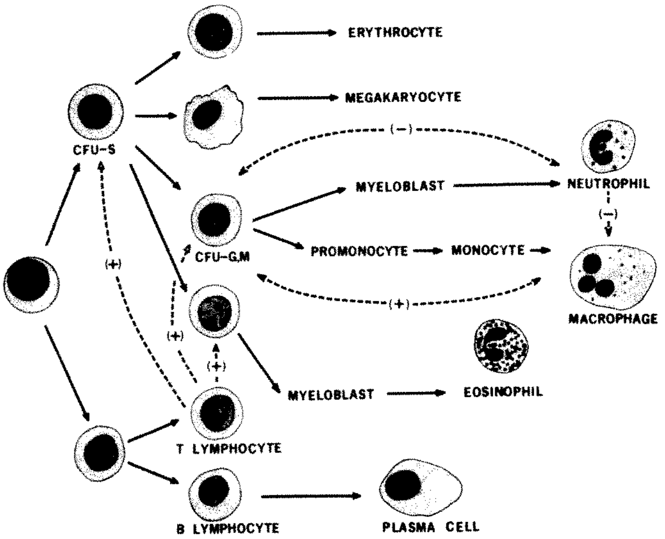

Fig. 1 Granulopoiesis is thought to be regulated by glycoprotein hormones (colony-stimulating activity, CSA) elaborated by monocytes, macrophages, and antigen-stimulated T lymphocytes. CSA acts on the committed myeloid stem cell (CFU-G,M) giving rise to both the neutrophilic granulocyte and the mononuclear phagocyte cell lines. Recent evidence also suggests that products of mature neutrophils may influence the production of both CSA and inhibitors of CFU-G,M by marcophages. If granulocyte chalones exist, they may also inhibit CFU-G,M. Stimulatory interactions are denoted by (+), possible inhibitory interactions by (−).

Only the placenta, certain fetal tissues, mononuclear phagocytes, and stimulated T cells have consistently been shown to serve as a source of CSA for human cells. Mononuclear phagocyte stimulation of granulopoiesis by CSA was the first important haematopoietic cellular interaction to be defined. The following features of this interaction are known: (1) blood monocytes, alveolar, hepatic and peritoneal macrophages all produce CSA[12-14]; (2) malignant monocytes of both mouse and man seem to retain CSA-producing capacity as long as some degree of monocyte differentiation is retained[15,16]; and (3) production of CSA is modulated by exposure of cells to endotoxin, PPD, zymosan, glucan and poly I:C (refs 17, 18). The production of CSA by mononuclear phagocytes has led to a concept of positive regulation of granulopoiesis and monocytopoiesis by products of the responding cells themselves (Fig. 1).

Another important source of CSA is the T lymphocyte. Early observations of granulopoiesis in mice indicated that serum CSA levels were increased in primed animals exposed to antigen. It was subsequently demonstrated *in vitro* that antigen- and mitogen-stimulated T lymphocytes produce CSA, thereby providing an explanation for the *in vivo* phenomenon[19-21].

Monocyte- and lymphocyte-derived CSA are similar and have higher molecular weight components than placental CSA[9]. We have recently established from a patient with a T-cell variant of hairy cell leukaemia (leukaemic reticuloendotheliosis) a line of T cells that produces potent CSA[22]. Production is increased, particularly after exposure of the cells to phytohaemagglutinin (Table 1). This human lymphocyte-derived CSA is sensitive to trypsin and is bound by concanavalin A (Con A).

We conclude that intense antigenic stimulation may stimulate neutrophilic granulopoiesis and monocytopoiesis by an interaction with T lymphocytes mediated by a particular species of CSA. Certain malignant T cells retain this stimulatory capacity.

Negative feedback

We have considered positive controls of the production of phagocytes. Various investigators have also emphasised theoretical reasons why granulopoiesis should be under negative feedback control and have adduced evidence for the existence of granulocyte chalones[23,24]. Chalones are defined as tissue-specific, species-nonspecific products of differentiated cells that selectively inhibit early cells of the same lineage[25]. A putative neutrophilic chalone would be a product of mature neutrophils that would specifically and reversibly inhibit the proliferation of neutrophil precursors but not other dividing cells. Although an inhibitory effect of human granulocyte chalone on human acute leukaemia has recently been reported[26], the existence of granulocyte chalones is controversial. For example, we were unable to find neutrophil-inhibitory products that demonstrate the requisite cellular specificity[27,28].

Another category of possible negative regulators of myeloid stem cells is that of neutrophil-derived factors that inhibit cells producing CSA. Broxmeyer *et al.*[29,30] reported that crude extracts of normal, but not chronic myelocytic leukaemic, neutrophils inhibit the production of CSA by monocytes and macrophages. They therefore postulated that negative feedback from the normal mature neutrophil acted at the level of CSA generation and not at the CFU-G,M level.

Prostaglandins of the E series (PGE_1 and E_2) are potent inhibitors of CFU-G,M proliferation (activity at 10^{-10} M), whereas those of the F series are often stimulatory. The effect of PGE can be overcome with CSA. Human monocytes and mouse macrophages produce both CSA and PGE. High concentrations of macrophages inhibit CFU-G,M growth, and this inhibition is overcome with indomethacin[31,32]. Based on these observations, Kurland and Moore have evolved an elaborate scheme whereby granulopoiesis is modulated by macrophage generation of stimulatory and inhibitory products which in turn is modulated by neutrophil inhibitors and CSA[29-32]. While this scheme remains tentative, the best-defined cellular interaction in granulopoiesis is the positive stimulation of granulopoietic progenitors by products of mononuclear phagocytes and stimulated T lymphocytes (Fig. 1).

Erythropoiesis

The primary control of erythrocyte production is determined by a balance between tissue-oxygen needs and the capacity of the oxygen delivery system, and is mediated by erythropoietin. Recent studies suggest that interactions between erythroid precursors and other cells, particularly the T lymphocyte, may also modulate erythropoiesis.

Two general categories of erythroid precursors have been identified *in vitro*; first, the erythroid colony-forming unit (CFU-E), which is an immediate precursor of the differentiated normoblast and is capable of only three to six divisions; second, the burst-forming unit (BFU-E), which is a more primitive committed erythroid stem cell with potential for many more divisions. The CFU-E is thought to arise from the BFU-E[33]. The CFU-E is sensitive to erythropoietin whereas the BFU-E is relatively insensitive. In the intact animal BFU-E proliferation is influenced by stimuli to marrow regeneration but not by changes in erythropoietin concentration[34]. BFU-E normally circulate in the peripheral blood of man and are found in the null-cell mononuclear leukocyte fraction[35]. When T cells are removed from this fraction, burst formation is diminished; when T cells are restored, so are BFU-E. Other evidence for T-cell–erythropoietic interactions comes from studies of diffusion chambers containing proliferating haematopoietic cells implanted intraperitoneally in mice[36]. Phytohaemagglutinin (PHA)-treated marrow cells or thymocytes added to bone marrow cell suspensions in such chambers greatly stimulate erythroid colony formation (Table 2). Pretreatment with anti-θ serum and complement eliminates the stimulatory effect of the mitogen.

A third line of evidence for a T-cell–erythroid interaction comes from a report that infusion of normal littermate bone marrow depleted of T cells does not cure the genetically determined anaemia of the W/W^v mouse, whereas addition of normal T cells to the marrow results in cure[40]. A fourth line of evidence comes from the observation that medium conditioned by an established T-cell line[22] has erythroid burst-promoting activity. The conditioned medium potentiates the effects of erythropoietin but cannot substitute for the hormone (Table 3). Erythroid burst-promoting activity is reported to be separable from CSA activity in other systems[41].

Several types of evidence therefore suggest that T lymphocytes and their products affect early erythroid progenitors and may thereby interact with erythropoietin in controlling erythropoiesis. Less strong evidence supports a role for mononuclear phagocytes in erythropoiesis. The evidence is essentially morphological and derives from the observation of macrophage-like cells within the bone marrow in the centre of islands of developing erythroid precursors[42]. The effect, if any, of macrophages may be mediated by the prostaglandins which they produce, as PGE_1 causes increased elaboration of erythropoietin by the kidney and has direct effects on stimulating glucosamine uptake and iron incorporation into red-cell progenitors. PGE_1 also stimulates erythroid colony formation *in vitro*. It has recently been suggested[43] that erythropoietin is produced by macrophages in the liver, the major source of extrarenal erythropoietin[44,45]. Alternatively, the generation of erythropoietin in the liver may depend on PGE_1 production by the Kupffer cell, which in turn regulates erythropoietin elaboration by hepatocytes. Circumstantial but not direct evidence therefore links mononuclear phagocytes to erythropoiesis.

Lymphocyte–macrophage interactions

The interactions between mononuclear phagocytes and T and B lymphocytes in antigen processing in the afferent limb of the immune response are so well documented[46] that it is only worth noting their cardinal features. First, they generally require close contact between the mononuclear phagocyte and the responding lymphoid cell. Intact viable mononuclear phagocytes are necessary for optimal response. Surface antigenic identity between the mononuclear phagocytes and the subsequently responding lymphoid cell is generally necessary. Mononuclear phagocytes potentiate the production of biologically active lymphokines, as well as B-lymphocyte antibody responses. Finally, in at least some *in vitro* culture systems, the requirement for mononuclear phagocytes can be replaced by mercaptoethanol and possibly other thiols.

Table 1 Production of CSA by an established human T-cell line

Addition to culture	Duration of culture (d)	Colonies per 10^5 marrow cells
—	2	130 ± 22
—	6	105 ± 20
PHA	2	260 ± 18
PHA	6	272 ± 24

Conditioned medium was prepared from a continuously growing human T-cell line cultured in the presence and absence of PHA and assayed for its ability to stimulate granulocyte–macrophage colonies from non-adherent human bone marrow cells.

The interaction between T lymphocytes and mononuclear phagocytes also operates in the reverse direction: T cells can influence mononuclear phagocyte proliferation, differentiation, and activation[46,47].

Eosinophilopoiesis

Basten *et al.*[48,49] demonstrated a role for large lymphocytes in the mediation of the eosinophilic response to *Trichinella* infection in rats. Irradiated animals developed an eosinophilia in response to parasitic challenge only when reconstituted with lymphocytes as well as bone marrow cells. Marrow alone did not suffice. When lymphocytes from sensitised donors were used together with normal marrow cells, a 'secondary' type of eosinophilic response occurred. In other experiments, neonatal thymectomy significantly reduced the capacity of both mice and rats to mount an eosinophilia in response to antigen[50].

These studies in intact animals have been refined by studies in diffusion chambers implanted in mice and by *in vitro* culture systems[51,52]. Ruscetti *et al.* added medium conditioned by sensitised splenic lymphocytes and *Trichinella spiralis* antigen to marrow cells from *Trichinella*-infected mice. They observed a three- to fourfold increase in eosinophils in liquid culture. The response was antigen specific as neither pokeweed mitogen nor PPD stimulated the release of eosinophil-stimulating factor. Collectively these experiments suggest that thymus-derived or thymus-dependent cells may modulate eosinophilopoiesis in response to antigenic challenge. In addition, T-lymphocyte products may influence eosinophil migration[53]. The granulopoietic and eosinophil responses to the soluble products of sensitised T lymphocytes are probably independent, as studies from *in vitro* culture of marrow from children with congenital neutropenia and other observations[54] support the notion of separate committed stem cells for neutrophils and eosinophils.

Table 2 Stimulation of erythroid colonies from murine bone marrow in diffusion chambers implanted in normal mice

Cells added to chambers	Erythroid colonies per chamber
Bone marrow	1.6 ± 0.8
Bone marrow + PHA	31.9 ± 7.2
Bone marrow + thymocytes	1.7 ± 1.2
Bone marrow + PHA + thymocytes	63.0 ± 22.0

Bone marrow cells (1×10^5) or thymocytes (2×10^4) were incubated for 30 min with or without PHA (0.01 ml per ml) and washed twice. In all cases 100,000 bone marrow cells were implanted in Millipore chambers containing a plasma clot. Erythroid colonies were counted 3 d after peritoneal implantation of chambers in host mice (ref. 36, and E. Niskanen, unpublished observations).

Cellular interactions with pluripotent stem cells

Relatively little is known about the factors influencing proliferation of pluripotent stem cells (CFU-S) or their commitment to a single line of differentiation. Under normal circumstances CFU-S do not actively proliferate. With increased demands for haematopoiesis, as after subtotal irradiation, the CFU-S compartment begins to expand. The signals for proliferation in the intact animal are not known. *In vitro*, PGE_2 has been reported to induce CFU-S to enter the proliferative cell cycle[55]. PGE is one of the biologically active products of the macrophage and, in theory, is a potential mediator of several haematopoietic cell interactions.

Table 3 Erythroid burst-promoting activity of medium from a human T-cell line

Addition to culture	BFU-E per 2×10^5 cells*
None	0
Epo, 3µl per ml	13±2
Epo, 3µl per ml + T-cell medium, 50 µl	42±3

*Light density human peripheral blood leukocytes.

Cerny[56,57] described another possible interaction. He reported that the number of CFU-S increased in spleen cell suspensions treated with phytohaemagglutinin (PHA). The effect was ablated by pretreatment with anti-θ serum and complement. Furthermore, conditioned medium from PHA-treated spleen cells increased the numbers of CFU-S in bone marrow two- to threefold. Pritchard[58] showed that thymocytes augment spleen colony formation when injected with marrow cells. Recent observations suggest that thymectomised mice or nude mice deficient in T cells may also demonstrate abnormalities of haematopoietic stem cell function[59]. If corroborated, these many observations suggest the existence of yet another T-cell interaction with haematopoietic stem cells.

Stromal cell interaction

Another important class of haematopoietic interactions is that between proliferating haematopoietic cells and the stromal cells of blood-forming organs. At present, this class of interactions is the least understood. After transplantation into irradiated syngeneic mice, haematopoietic stem cells proliferate with a doubling time of 20–25 h. The major sites of cellular proliferation are the spleen and the medullary cavity. The rate of stem cell replication and the direction of differentiation are partly determined by factors derived from the organ of lodgment and collectively referred to as the haematopoietic inductive microenvironment (HIM) or the 'stroma'. Some of the factors seem to be under genetic control[60,61].

The murine bone marrow and spleen stroma can support differentiation of pluripotent haematopoietic stem cells along four pathways: erythroid, neutrophilic, eosinophilic, and megakaryocytic[60,61]. Splenic haematopoiesis, however, is prominently erythroid, whereas granulopoiesis is more evident in the bone marrow. The effects of the stromal microenvironment on stem cell differentiation are presumed to be mediated by short-range cellular interactions.

An elegant and clear demonstration of the effect of the HIM on haematopoietic cell differentiation was provided by Wolf and Trentin[60]. They implanted plugs of bone marrow stroma in the spleen and studied the pattern of growth of transplanted haematopoietic stem cells growing across the junction of such implants. On the spleen side, the colonies were predominantly erythroid, and on the marrow side, predominantly granulocytic. Subsequent investigations have suggested that an abnormal HIM for erythroid differentiation is responsible for the genetically determined anaemia of sl/sl^d mice[37–39,61].

There have been few attempts to study organ influences of haematopoiesis *in vitro*. Metcalf found that lymphocytes and thymocytes potentiated colonial bone marrow growth *in vitro*. Subsequently, Chan and Metcalf observed that femoral bone shafts could condition medium to support the growth of marrow colonies[62]. Dexter *et al.*[63–65] have recently developed a liquid culture system in which proliferation of mouse haematopoietic stem cells can be maintained *in vitro* for long periods. In this system, marrow-derived adherent cells established in culture for three weeks are inoculated with freshly isolated bone marrow cells. The latter subsequently proliferate for several months and retain viable CFU-S and CFU-G,M. Their proliferation depends upon the adherent population comprised of phagocytic mononuclear cells, or 'epithelioid' cells, and giant fat-containing cells which seems to provide an *in vitro* microenvironment. Within this adherent layer, extensive cellular interactions occur. Marrow-derived adherent cells from a particular mouse strain can stimulate the growth of haematopoietic cells from genetically incompatible, as well as syngeneic, mice. Dexter and Moore have recently shown functionally abnormal adherent feeder layers derived from sl/sl^d mice[65].

We have also used suspension and agar cultures of mouse bone marrow to study the effects of organ stromal factors on cellular proliferation and differentiation *in vitro*[66]. Bone, spleen, and thymus fragments from irradiated mice were placed in contact with syngeneic bone marrow cells growing in suspension culture. Neutrophilic granulocyte numbers were greatest in the presence of bone or spleen. The stromal microenvironment of, those tissues thus influences haematopoietic cell differentiation as well as proliferation *in vitro*, possibly by means of a CSA-like factor.

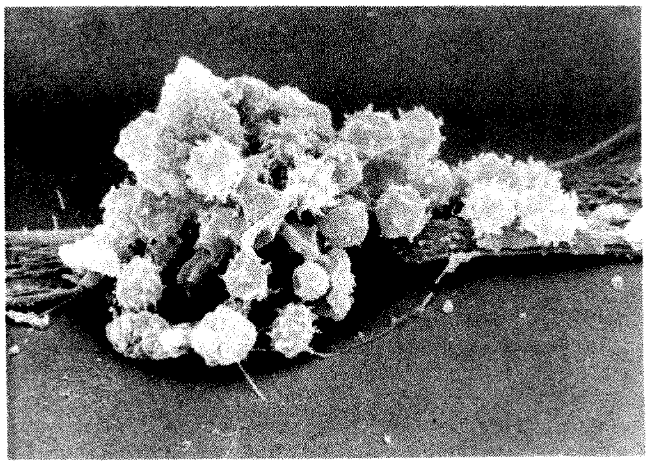

Fig. 2 Scanning electron photomicrograph of cells in long-term culture of human bone marrow. Adherent cells are established in culture before the system is 'recharged' with a fresh inoculum of bone marrow cells. The small round cells proliferate on the surface of larger adherent cells for several weeks and can be assayed in gel-matrix culture as CFU-G,M and CFU-E (photograph courtesy of Dr William Hocking and Shirley Quan of UCLA).

Recently the culture system developed by Dexter *et al.*[63–65] has been applied to the cultivation of human bone marrow. In this system, CFU-G,M and CFU-E are preserved for several weeks. As in the murine system, large stromal cells as well as smaller round proliferating cells are in intimate contact in the growing cultures (Fig. 2). The interactions between these cells which are crucial for proliferation and differentiation are still undefined. Nevertheless, these new culture techniques do provide the means to explore stromal cell interactions.

Leukaemia

In acute myeloid leukaemia, abnormal haematopoiesis results in anaemia, thrombocytopenia, and decreased granulopoiesis. Are the normal haematopoietic cells replaced by leukaemic cells in the blood-forming organs or are they suppressed by humoral factors produced by leukaemic cells? The latter explanation is suggested by cytogenetic studies which reveal that normal haematopoietic clones are present but do not expand until the leukaemic cell mass is reduced by chemotherapy.

Leukaemic cells co-cultivated with normal marrow cells suppress granulopoiesis[67,68]. The basis of this may be in the high molecular weight inhibitor of normal human granulocyte stem cells that we have identified in a previously described myeloid leukaemia cell line[69,70]. This inhibitor also affects mitogen-stimulated human lymphocytes but not erythroid precursors, normal fibroblasts, or various epithelial cell lines (Table 4). It has a molecular weight greater than 100,000, demonstrates species specificity, adsorbs to Millipore filters, and is inactivated by heat at 56 °C after 30 min. Its effect on sensitive stem cells is reversible in a time- and concentration-dependent fashion. It does not seem to affect either the S-phase of the cell cycle or mitotic events. We do not yet know if similar inhibitors are present in clinical leukaemia.

Another consideration is whether leukaemic cells retain responsiveness to normal cellular interactions and haematopoietic hormones. In general, human acute myeloid leukaemic cells in agar gel form small clusters of 4 to 20 cells rather than true colonies of 50 to several hundreds of cells. Nor is there much evidence of cytodifferentiation *in vitro*, although many leukaemias show both enhanced cluster and colony formation in response to CSA. It has been speculated that acute myeloid leukaemia sometimes results from a defect in the haematopoietic environment and its controlling hormones[71]; however, based on the observations cited and the demonstration that leukaemic cells retaining monocytic features can make CSA, it seems unlikely that the primary abnormality in leukaemia resides in the hormonal environment. The fundamental defect seems to be a loss of the ability to differentiate in response to normal hormonal signals and cellular interactions.

Concluding remarks

A variety of cellular interactions control the production of blood cells in haematopoietic organs. These interactions include the involvement of T lymphocytes in granulopoiesis, monocytopoiesis and erythropoiesis; and mononuclear phagocyte interactions in granulopoiesis, in T-lymphocyte differentiation, and perhaps in erythropoiesis. The stromal cells of haematopoietic organs provide a unique microenvironment which influences the development of stem cells.

The rich diversity of haematopoietic cellular interactions may serve as a model for interactions in other tissues and organs comprised of multiple cell types. Blood cell interactions have been elucidated *in vivo* in animal models and *in vitro* in recently developed culture systems applicable to human studies.

For several years cellular interactions affecting haematopoietic cell proliferation and differentiation have been described in terms familiar to cell biologists: for example, the activation of macrophages by soluble products of lymphoid cells is well established[46]. More recently, permanent lines of haematopoietic cells have provided tools for studying induced differentiation of eukaryotic cells at the molecular level[72,73]. It is likely that these model systems will provide the ultimate explanations of the influence of one cell upon the proliferation and differentiation of its neighbour. It is also possible that the techniques used to examine these interactions may have unanticipated benefits for the treatment of human disease. For example, it has recently been reported that mixtures of haematopoietic stem cells cultured for long periods *in vitro* can change their antigenic characteristics and subsequently proliferate in host animals which would ordinarily reject their growth[74]. This observation may have important implications for the biology and technology of human bone marrow transplantation for aplastic anaemia and malignant disease. Currently such transplantation is restricted to donors and recipients possessing haematopoietic cells which are closely similar in surface antigenic structure. The possibility that one could artificially alter that structure is challenging.

Table 4 Inhibition of proliferating cells by medium from a myeloid leukaemia cell line

Target cells	Inhibitor concentration v/v	Inhibition of growth (%)
Human CFU-G,M	1:100	98±2
Human CFU-E	1:10	64±4
	1:100	6±4
Mouse CFU-G,M	1:10	74±6
	1:100	23±5
Human fibroblasts	1:10	2±2
Human epithelioid cells 253J	1:10	0±2
Human T lymphocytes (PHA)	1:10	82±6

Superluminally expanding radio sources and the radio-quiet QSOs

P. A. G. Scheuer
Mullard Radio Astronomy Observatory, Madingley Road, Cambridge, UK

A. C. S. Readhead
California Institute of Technology, Pasadena, California 91125

We propose a model of apparent superluminal expansion based on straightforward relativistic motion. The model gives a natural explanation of the ratio of radio-quiet to radio-loud quasars.

THE expansion of the double structures of quasars revealed by VLBI[1,2] at apparent separation speeds exceeding $2c$, has posed an intriguing problem; the numerous suggestions that have been made for its solution have been classified and discussed by Blandford *et al.*[3]. Theories of the type they call 'ballistic', in which radio-emitting matter is projected at $v \sim c$ in directions making small angles θ with the direction towards the observer, have been current for a long time, and a version involving spherically symmetrical relativistic expansion was originally devised by Rees[4] to account for the rapid variability of certain powerful radio sources. In a two-component version of the theory, the approaching component has apparent transverse speed $v \sin \theta/(1-(v/c) \cos \theta)$ and apparent power $P_0\{\gamma(1-(v/c)\cos \theta\}^{-(3+\alpha)}$; for the receding component v is replaced by $-v$ (ref. 5) (P_0 is the radio power per Hz in the component's rest frame, and α its spectral index in the sense $P \propto \nu^{-\alpha}$). The maximum apparent transverse speed occurs when $\sin \theta = 1/\gamma$ and is γv; thus an apparent speed of $5c$ calls for γ a little >5.

The traditional difficulties with this type of model are: (1) if their intrinsic powers are at all similar, the receding component has a flux density very much smaller than that of the approaching component; even for modest v/c this ratio is large (see ref. 6) and for $\theta \sim 1/\gamma$ with $\gamma \geq 2$ the receding component should be quite unobservable. This totally disagrees with the reported fairly symmetrical double structure. (2) In a randomly orientated sample of sources, very few have axes sufficiently close to the line of sight to reach large v_{apparent}/c; for example, for $\gamma = 5$ the proportion with $\sin \theta < 1/\gamma$ is 2%. However, superluminal velocities are observed in a large proportion of the quasars that have been observed systematically by VLBI.

Lynden-Bell[7] has shown one way out: he postulates that the ejecta merely excite the surrounding (~stationary) matter to emit radio waves, thus avoiding difficulty (1), and removes (2) by using a large value of Hubble's constant, so that only modest γ's are needed.

Another way is to suppose that the observed VLBI 'doubles' consist of approaching components only. In this scheme the appearance of an expanding double is due to a bright knot in the approaching stream, together with radio emission continually regenerated near the quasar nucleus; a relatively small total energy is enough to provide observable radio emission from a very compact source near the nucleus, but the amount of radio emission there is limited by synchrotron self-absorption, so that we may expect the radio emission close to the nucleus to fluctuate rather less than the energy supply. Difficulty (1) is then irrelevant, and (2) is attributed to a selection effect, sources approaching with high γ and small θ being observed often because of their high apparent radio power. The much larger number of similar sources with large θ are then to be identified with some or all of the radio-quiet quasars, which are optically very similar to quasi-stellar radio sources (QSRS). We have favoured this model for some time, but the stimulus to working out its consequences more seriously came from recent work at Caltech[8-12] which shows that, in six out the eight cases observed, the VLBI structures in fact consist of a (so far) unresolved, self-absorbed component at one end, and a single 'jet' (with a steeper spectrum) emerging from it.

The six sources showing clear core-jet structure are 3C120, 3C147, 3C273, 3C286, 3C345, 3C454.3; the two other sources, CTA102 and 3C380, show no striking asymmetry, but have so far been observed at only one frequency.

Here we define the nature of the model we propose; compute the ratio of total optical QSO numbers to QSRS that it requires; examine the problem of compact central sources associated with large classical doubles; and point out some other observational consequences of the model.

The model

We postulate that the radio-emitting objects are ejected often, or continually, but by no means steadily, along one axis. Thus there is always some radio emission close to the QSO, but all the radio-emitters on the approaching side are moving with similar velocities. (A stationary nuclear component would have flux density independent of orientation, and thus defeat the model through difficulty (2)). We must suppose, however, that much of the light comes from a stationary source, as the line emission does not have large v/c (otherwise blueshifts would occur), and the line: continuum ratio does not vary really drastically from one quasar to another. The model would not be inconsistent with an appreciable fraction of the continuum originating in the relativistic jet in some cases, and indeed such an interpretation would be required if a strong trend for greater optical variability among QSRS than among QSOs as a whole (see ref. 13) is confirmed.

0028-0836/79/0277—0182$01.00

We need a range of γ extending up to at least 7 (to account for v_{apparent} in 3C345), and down to 1.5 or less to account for the less powerful but relatively common central components of classical double radio sources. Though most of our calculations refer to quasars with only a single value of γ (and also of P_0, α, and optical luminosity) and we concentrate on the distribution in θ, a more thorough treatment will require model-building with distributions of these parameters.

Blandford has pointed out that, if a succession of pairs of components is ejected, and each lasts a given proper time (after which its radio emission fades), then at any instant we observe more of those on the receding side than on the approaching side; thus one Doppler shift factor disappears from Ryle and Longair's formula[5] for the apparent radio power, that is, the exponent becomes $(2+\alpha)$ instead of $(3+\alpha)$. The VLBI observations indicate that we are generally observing several components at once, so that our model will generally correspond more closely to Blandford's picture than to that of Ryle and Longair; hence we adopt an exponent $(2+\alpha)$ in our formulae, and show numerical results corresponding to the strict two-component model by giving α values 1.0 in excess of normal spectral indices.

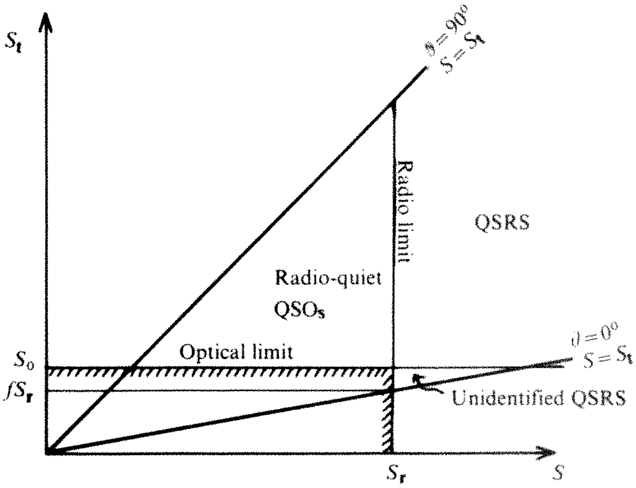

Fig. 1 The S (radio flux density) $-S_t$ (essentially optical flux density) plane. Sources exist between the lines marked $\theta=0^\circ$ and $\theta=90^\circ$.

The number of radio-quiet QSOs

In our model, the approaching half of the radio source gives essentially all its observed flux density S; if it lay transversely in the plane of the sky, it would have given a flux density S_t, where

$$S_t = S(1-(v/c)\cos\theta)^{2+\alpha} \tag{1}$$

(Thus a symmetrical double source with $\theta = 90^\circ$ would have flux density $2S_t$; as in our model the radio emission is very faint for sources with large θ, we shall ignore this fine distinction between S_t and $2S_t$.) We introduce S_t because it depends on distance like S, but is independent of θ, and for our standard quasar we can therefore regard S_t as a measure of the optical flux density.

For our rough estimate, we take the optical differential source count for quasars to be a power law

$$dN = KS_t^{-\beta-1}\,dS_t \tag{2}$$

The density of quasars in the S, S_t plane is then given by

$$\begin{aligned} dN &= KS_t^{-\beta-1}\,dS_t d(\cos\theta) \\ &= \frac{Kc}{v(3+\alpha)} S_t^{-\beta-1+1/(2+\alpha)} S^{-1-1/(2+\alpha)}\,dS_t\,dS \end{aligned} \tag{3}$$

(using equation(1)) in the band between the lines $S_t = S$ and

$$S_t = S(1-v/c)^{2+\alpha} = fS \tag{4}$$

Note that $f \ll 1$ even for modest values of γ: $f \lesssim 0.01$ for $\gamma = 2$ and $f \simeq (2\gamma^2)^{-(2+\alpha)}$ for large γ. If we set optical and radio limits of detection at S_0 and S_r, respectively, such that an appreciable fraction of the sources with $S > S_r$ are optically identified (Fig. 1), then $S_r \gg S_0$ and we find:

Fraction of QSRS with $S > S_r$ that are not optically identified =

$$\begin{aligned} &(1-f^{\beta-1/(2+\alpha)})^{-1}\{1-\beta(2+\alpha)(fS_r/S_0)^{\beta-1/(2+\alpha)} \\ &\qquad + ((2+\alpha)\beta-1)(fS_r/S_0)^{\beta}\} \end{aligned} \tag{5}$$

Fraction of QSO with $S_t > S_0$ which are also QSRS with $S > S_r$ =

$$\begin{aligned} &\frac{c}{v}\left\{\frac{\beta(2+\alpha)}{\beta(2+\alpha)-1}(S_0/S_r)^{1/(2+\alpha)} - (1-v/c) - \frac{1}{\beta(2+\alpha)-1}(S_0/S_r)^{\beta}\right\} \\ &\simeq \frac{1}{2\gamma^2}\left\{\frac{\beta(2+\alpha)}{\beta(2+\alpha)-1}(S_0/fS_r)^{1/(2+\alpha)} - 1\right\} \end{aligned} \tag{6}$$

We can safely set the first factor in equation (5) to unity; eliminating the quantity (fS_r/S_0) between equations (5) and (6) then lets us present the relationship between the fraction of unidentified QSRS and the fraction of QSRS in an optically selected sample in the simple form shown in Fig. 2.

Evidently, if most of the QSRS are optically identified (which is certainly true of flat-spectrum quasars), the ratio of total QSOs to QSRS is several $\gamma^2:1$; if all are identified $(S_0 < fS_r)$ the ratio exeeds $2\gamma^2\{\beta(2+\alpha)-1\}$ that is it is $>4\gamma^2$ for $\beta = 1.5$, $\alpha = 0$. The numerical factor does not depend critically on the proportion of unidentified quasars, or on β or α; thus if γ is typically 5, we expect about 1% of an optically selected sample to be radio sources. Furthermore, we expect the proportion to rise very slowly if we look with more sensitive radio telescopes; equation (6) shows that the proportion of QSRS rises roughly like $S_r^{-1/(2+\alpha)}$. This feature, too, is qualitatively entirely in agreement with observational experience.

The distribution of apparent velocities

We can gain insight into the apparent velocity distribution in a radio-selected sample by working in the approximation $\gamma \gg 1$, $\theta \ll 1$. To this approximation, the proportion of sources with radio flux density $S > S_r$ having $v_{\text{apparent}}/c > \gamma\sin\chi$ is

$$(\cos\tfrac{1}{2}\chi)^{2\beta(2+\alpha)-2} - (\sin\tfrac{1}{2}\chi)^{2\beta(2+\alpha)-2} \tag{7}$$

With $\beta = 1.5$, $\alpha = 0$ ($\beta = 1.8$, $\alpha = 1.5$), 87% (69%) of sources have $v_{\text{apparent}}/c > 0.5\gamma$ and 60% (31%) have $v_{\text{apparent}}/c > 0.8\gamma$. Thus apparent velocities comparable with γc are indeed expected to be very common in a radio-selected sample. (The exact figures are 82% (62%) and 39% (16%) at $\gamma = 2$, so the approximation is a fair guide even for small γ.)

Central components of classical double sources

In classical double radio sources, where the central component generally contributes little to the total flux density (especially at low frequencies), we should have a sample with random orientation of axes. However, a substantial fraction of such sources have central components whose properties seem to be qualitatively similar to compact sources without extended structure, and which are roughly aligned with the large-scale double in the few cases where VLBI measurements exist. No direct measurements of apparent expansion velocities exist yet. (We must exclude sources with extended structure on one side only, such as 3C273, also 3C345 and 3C454.3 (ref. 14) as in these, the extended structure might have substantial v/c). However, a few central components are known to be radio variables.

Clearly, very few of these central components can be sources with $\gamma \gtrsim 5$, as we have seen that for each such source there must be several γ^2 'radio-quiet sources'—here, doubles without observable central components—whereas it is observed that

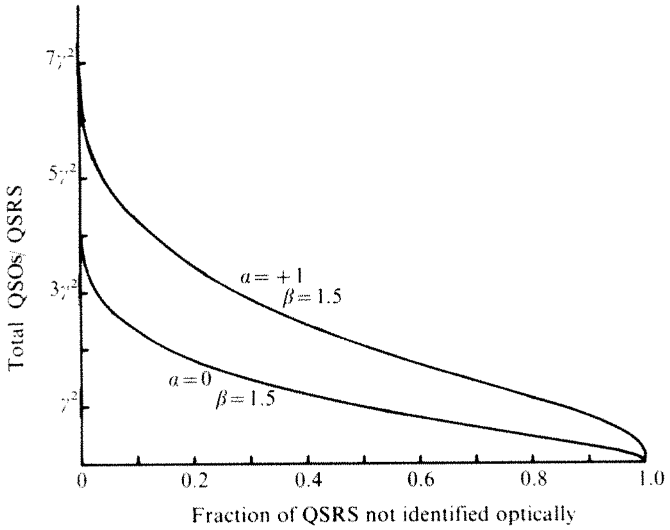

Fig. 2 The ratio of total quasars (radio quiet and QSRS) to QSRS alone, above given radio and optical limits, as a function of the fraction of unidentified QSRS in the radio-limited sample. The differential optical source count is assumed to be a power law with index $-(\beta + 1)$; the line $\alpha = 0$ represents flat-spectrum sources in mean, while the $\alpha = +1$ line represents either steep-spectrum sources or a strict 2-component model for flat-spectrum sources (see text).

~30% of 3C radio doubles (and more than half of the 3C quasars with extended double structure) have central components. We now make this argument a little more quantitative. For sources of identical γ, S_t and α, the distribution of apparent intensities due to their random orientations is given by

$$dN \propto d(\cos\theta) = \text{constant} \times S^{-1-1/(2+\alpha)}\, dS,\ S_t < S < S_t/f \tag{8}$$

and zero outside these limits. To estimate the largest γ we can allow as typical for central components, we compare equation (8) with the narrowest distribution we can find for S relative to some orientation-independent quantity, which is that of the ratio R of S to the flux density of the extended double structure. We use the complete sample of 166 3C sources selected at 178 MHz (listed in ref. 15). From it, we select those sources that: first, have large-scale structure on both sides of the optical position; second, are well enough resolved to yield an estimate or a useful upper limit for the flux density of the central component at 5 GHz (in some cases of doubtful interpretation, 15 GHz maps with 0.67" resolution have also been inspected); third, are identified with quasars.

We use only quasars because central components are commoner in them than in sources as a whole, so that they lead to a severer restriction on γ. (We should also exclude sources whose 178 MHz flux in extended structure alone would have fallen below the $S_r = 10$ Jy limit of the sample, but found no likely cases that had not already been excluded on other grounds.) The result (see Fig. 3) shows that a range of 64 : 1 in the ratio R is compatible with the observations; this corresponds to $\gamma = 2$. Even $\gamma = 2.5$ would be hard to reconcile with the observations: the total number of sources would then have to be six times the number in the top three octaves, that is, 36 instead of the 22 on our list. Of course, the true distribution is likely to contain a range of γ, extending from values close to 1 to $\gamma = 2.5$ and beyond; such a range of γ, together with a scatter in other instrinsic properties, would give a more bell-shaped distribution than equation (8).

We emphasise that there is no need to suppose that the central components of classical doubles are drawn from a population with a quite different γ distribution from that of the compact quasars; information available would allow us to ascribe the apparent difference solely to selection effects, for the central components by themselves would make very little difference to the counts of radio sources, or of quasars.

A more serious matter is the variability of central components. The observational evidence is still very sparse, and the most striking case we know is that of 3C111 at $z = 0.049$, whose central component has been known to vary by 2 Jy in 0.4 yr (R. G. Hine, personal communication). This rate of variation would be compatible with conventional electron synchrotron emission for a component speed corresponding to $\gamma \sim 2$, or rather less if the component is itself expanding with mildly relativistic speed.

The radio source counts at high frequencies

It is well known that the radio source counts at high frequencies (2.7 and 5 GHz) deviate much less from a power law with $\beta = 1.5$ than do the source counts at 408 MHz and lower frequencies (see ref. 16). There are two ways in which this fact could be related to the present model.

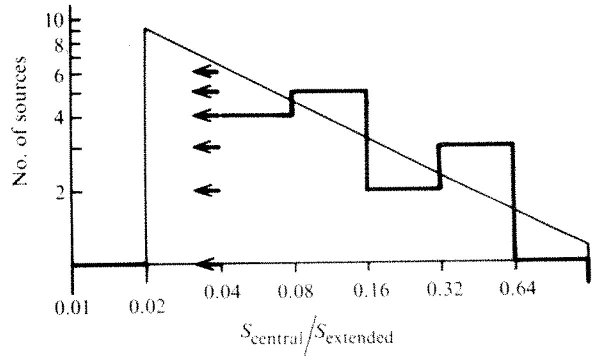
First, the distribution of S with orientation (equation (8)) introduces a broad scatter in apparent radio luminosity in addition to the intrinsic radio luminosity function. This might be expected to flatten out the hump in the graph of normalised source counts versus S (Fig. 1 of ref. 16) at high frequencies, where the source counts are dominated by flat-spectrum quasars, but not at low frequencies, where the source counts are dominated by classical doubles and orientation effects are therefore unimportant. In fact, this effect is far too small to account for the observed difference between low and high frequency counts, because the distribution in equation (8) is so much less steep than the source counts. Numerical convolution of the 408-MHz source counts (from ref. 16) with distributions given by equation (8) flattens the graph of normalised source counts slightly though noticeably at low flux densities, and changes its slope very little indeed at high flux densities.

Second, it is also well known that low-powered radio sources evolve far less strongly than high-powered radio sources. In the present model, the flat-spectrum quasars are sources of low intrinsic radio luminosity, promoted to high flux density by high speed and favourable orientation. Thus the present model may provide a link between the relatively slow evolution of flat-spectrum quasars and the relatively slow evolution of weak radio sources.

The curvature of the VLBI structure

Readhead *et al.*[10] have considered the VLBI structure of radio sources which have extended components on either side of the optical object, and of sources in which the extended structure, if any, is one-sided and a dominant compact (<0.1") radio

Fig. 3 Histogram of the numbers of classical double quasars with various ratios of central component flux density to extended component flux density (note log scales). The thin line is the predicted distribution for the model sources with flat spectra ($\alpha = 0$) expanding at $\gamma = 2$, fitted to the histogram; larger γ would require a larger range along the abscissa, and hence a greater number of sources without observable central components.



component is coincident with the optical object. They call these type S and type C objects, respectively, and find that, in those type S objects that have a sufficiently bright central radio component to be studied by VLBI, this structure is well aligned with the outer components (five cases). Conversely, in type C objects the compact component is generally curved (four cases). If our model is correct, the fact that curvature is seen at all implies that the opening angle of the jet is considerably less than $1/\gamma$. The curvature observed, projected on to the plane of the sky, will be the instrinsic curvature of the jet magnified by a factor cosec θ, that is a factor $\gtrsim \gamma$ according to our model. Thus our model leads us to expect much greater curvature in type C sources (large γ, small θ) than in type S sources (small γ, random θ). The curvature observed in type C sources ranges from 20° to 45°.

Conclusions

We believe that the model suggested here is consistent with the known facts about quasars. The model lacks ingenuity, and we regard that as one of its merits. The model is a fragile one; the clearest and cleanest evidence against it would be the detection of large superluminal apparent expansion velocities in the central components of even a few quasars with extended double structure. As a preliminary to looking for such evidence we hope to encourage more extensive monitoring of flux density variations in such central components.

We note that the high speeds of approach in the present model increase the limit on apparent surface brightness imposed by the onset of inverse Compton scattering; thus it is rather easier to account for rapid variability below 1 GHz[17,18] than it would be in models in which the radio emitters are static.

Much more detailed model-building will be required to find out whether the model is consistent with all aspects of quasar statistics, such as their distribution in redshift and in optical luminosity. We have also treated the radio components as being ejected into an infinitesimal cone at a single value of θ; ejection into a finite range of θ could have substantial effects on the statistics. The different typical γs required for compact quasars and quasars with extended double structure seem at first to be a very contrived feature of the model, but it seems to us that this difference can arise largely or entirely as a result of the different methods of selection. We are much less happy about the need to attribute relativistic speeds to the single-ended extended structures in 3C273, 3C345, and 3C454.3, though we are consoled by the facts that (1) these extended structures are in all three cases on the same side of the most compact components as is the jet, and (2) two such structures (in 3C273 and in 3C274 (M87)) are also distinguished from other extended radio structures by their strong optical continuum emission.

We thank Drs R. D. Blandford and J. V. Wall.

The observed dielectric response of most materials is seldom in accord with Debye behaviour, but has been found experimentally to exhibit a remarkable 'universality.' It is proposed that this universality is a consequence of some ubiquitous correlated states which exhibit an infrared (IR) divergent-like response to induced transitions of the polarising species.

IN a recent detailed survey[1-4] of the dielectric response of a wide range of solids, it was concluded that the time or frequency response departs strongly from the Debye response and that it falls into a remarkably common or 'universal' pattern in which the frequency dependence of the dielectric loss follows the empirical law

$$\chi''(\omega) \propto \omega^{n-1} \quad \text{with} \quad 0<n<1 \tag{1}$$

extending over several decades of frequency from the lowest audio and sub-audio range to $\omega/2\pi \simeq 10^9$ Hz, in a remarkably wide range of different materials. The corresponding time-domain response of the depolarisation current is given by the Fourier transform of equation (1) and has been known for many years as the Curie–von Schweidler law:

$$i(t) \propto t^{-n} \tag{2}$$

The universal response applies to permanent dipoles and to hopping charge carriers of electronic, polaronic and ionic nature. It is valid in solids with covalent, ionic and molecular bonds, in single crystals, polycrystalline and amorphous structures, and hence is apparently independent of the particulars of the material. At higher frequencies, in excess of 10^9 Hz, quantum effects involving lattice mode excitations and/or electronic excitations become prominent but these will not interest us in the present context.

The various types of dielectric response are summarised[4] in Fig. 1. We note the virtual absence of the pure Debye behaviour. In dipolar materials the universal response, equation (1), is followed at low frequencies by a loss peak of either the α or the β type, while in systems dominated by hopping charge carriers

0028–0836/79/0277—0185$01.00

another universal response with very small values of n, typically between 0.1 and 0.3, follows at low frequencies[5].

The totality of these experimentally ascertainable facts is not compatible with any of the numerous theories that have been proposed in the last half-century to explain the behaviour of this or that particular class of materials and the need to invoke many-body interactions to account for the generality of equation (1) has been suggested[2-4]. The possible connection of this behaviour with infrared divergent response has also been conjectured (K. L. Ngai, unpublished).

This state of affairs has motivated us to seek a more fundamental understanding of the universal behaviour in terms of physically simple and 'elementary' properties. We will present here several elementary principles which when combined will enable a derivation of the universal law shown in equation (1) to be made regardless of the physical, chemical and geometrical properties of the solids, and also regardless of the nature of the electrically active species responsible for polarisation, whether dipoles, electrons or ions. We will also discuss several examples of low energy excitations expected in various systems that satisfy these elementary principles. We shall derive the universal response (1) and briefly mention the possible presence of a loss peak at lower frequencies.

IR divergence and the universal law

IR divergence phenomena, although not commonly observed in physics, have been seen in several instances, notably in quantum electrodynamics as bremsstrahlung[6], and in solid state physics[7,8] as the peculiar shape of X-ray absorption edges of metals[9]. These examples are not exhaustive but the subjects they cover demonstrate that IR divergence is not uncommon.

The features common to systems exhibiting the IR divergence are: (1) the sudden application of a potential, or a sudden change of the potential or the hamiltonian; and (2) the availability of low-energy excitations of the system and its response to the sudden potential change dominated by the emissions of these low-energy excitations.

In the time domain, the phenomenon is the transient response[10-12] of the system to that abrupt change of potential. IR divergence occurs whenever the suddenly switched on potential V excites some low energy excitations, with a density of states $N(E)$ for excitation energy E, which is such that $V^2(E)N(E) \propto E$. In this instance there is an increasingly high probability of exciting decreasingly small energy excitations and this causes a power-law divergence of the response in the frequency domain, equation (1), or its time-domain equivalent, equation (2). In the X-ray edge problem in metals an absorbed X-ray photon suddenly switches on a hole–core potential V for the conduction electrons. The low-energy excitations here are the electron–hole pairs.

We shall propose later that within a broad classification of dielectrics some ubiquitous states exist that, for convenience, we shall refer to as correlated states. Low energy excitation of the correlated states with excitation energy E consists of removing an 'occupied' state to an 'unoccupied' state and is the analogue of the electron–hole pair excitation in the X-ray edge problem. Due to induced transitions of the charged particles or dipoles responsible for the polarisation of the dielectric, a potential V is turned on acting on these correlated states. Hence the response of the dielectric involves emission of correlated state excitations. We shall argue in a specific example given that the low energy excitations of these correlated states have a density of states $N(E) \propto E$, and the potential change V has little or no E dependence. Furthermore, V may be taken as suddenly applied as the polarising species of the dielectrics should undergo quantum transitions, including changes in their positions/orientations, between preferred states in an abrupt manner by hopping or jumping movements[1-4] such that the time $1/\nu$ taken by the actual transition is negligible in comparison with both (1) the time spent on average in the respective preferred states, and (2) the time characteristic of the low energy excitation of the correlated states. Condition (1) is invariably satisfied in solid dielectrics. That condition (2) is also satisfied will become clearer after we have considered the nature of the correlated states. It then follows that the requirements for an IR divergent dielectric response of the correlated states are satisfied. The mean number p of correlated state excitations is then $p = b\int_0^{E_c} V^2 N(E)dE/E^2$, which diverges logarithmically, where E_c is the upper 'cut-off' at the correlated state excitation energy.

It is interesting that the IR divergence problem when considered in the time domain as a transient response problem[10-12] does lead to the time decay of the response function for large times as t^{-n}. The derivation of the complete dipolar loss peak response will be discussed elsewhere, meanwhile we discuss the correlated states in a broad classification of dielectrics.

Correlated states

We have connected the universal law, equation (1), to an IR divergent response of correlated states. For this interpretation to follow, such states must be prevalent in dielectrics and have characteristic response times long in comparison to the switching of the hamiltonian. Below, we discuss several examples of such correlated states which can reasonably be expected to be present in many dielectrics. Note, however, that although these examples are quite general, they are by no means exhaustive. Furthermore, the first class of correlated states which we discuss (those related to spin density fluctuations) is not the most general as the majority of dielectrics are diamagnetic. We have chosen this class for initial consideration because the resultant analysis facilitates the treatment of the more important classes of correlated states considered subsequently.

(1) Dielectrics with localised spins: new concepts and ideas on low-energy excitations in spin glasses (and real glasses) have been recently introduced by Anderson *et al.*[13], Phillips[14] and by Anderson[15]. They propose the existence of a statistical distribution of localised tunnelling levels and/or modes. In a spin glass, spins are considered as classical dynamical quantities with a potential energy surface that is a function of the simultaneously specified orientations of all the spins; local minima in the energy correspond to metastable states of the spin glass associated with different spin configurations. A tunnelling mode (TM) in a spin glass[13,15] is defined in spin configurational space as two local minima of energy difference ΔE separated by a quantum-mechanical energy barrier. Tunnelling between one local minimum and another, if it occurs, involves the rearrangement of several spins. The 'low' temperature linear specific heat observed in spin glasses comes from TMs with energy barriers that are sufficiently great so that resonant tunnelling of spins (atoms) between the local minima does not occur, but small enough so that tunnelling between the two levels can take place during the time span of the specific heat measurement.

Let us examine the transient response of these spin TMs to a sudden potential change, V, caused by fast quantum transitions of some charged species. Tunnelling modes whose alternate states are separated by more than $\sim \hbar\omega_0$, with $\omega_0 = 10$ GHz, can be eliminated at the outset for consideration of IR divergent response as our interest is in the low frequency dielectric behaviour where ω is smaller or much smaller than 10 GHz. Also, we need to consider only the very low energy TMs with quantum-mechanical energy barriers large enough so that the characteristic response time of the TM to V is long in comparison with the jump time of the polarisable species. This class of TMs should exist. Anderson[15] pointed out that as the configurations of the spins (atoms) is random, there must be very many locations (of order N; the number of spins or sets of spins), where there are two possible configurations of very similar energies E_1 and E_2. If E_1 and E_2 are independent random, variables, then the probability $P(\Delta E)$ of finding $\Delta E = |E_2 - E_1|$ is finite as $\Delta E \rightarrow 0$. But physically this is not true because it is possible to tunnel between the two alternate levels with a tunnelling matrix element T_{12} even though this is small for the TMs under consideration. The energy level separation will be at least $\Delta E \geqslant |T_{12}|$; the off-diagonal matrix element between the alternate levels. For the low frequency dielectric response (that

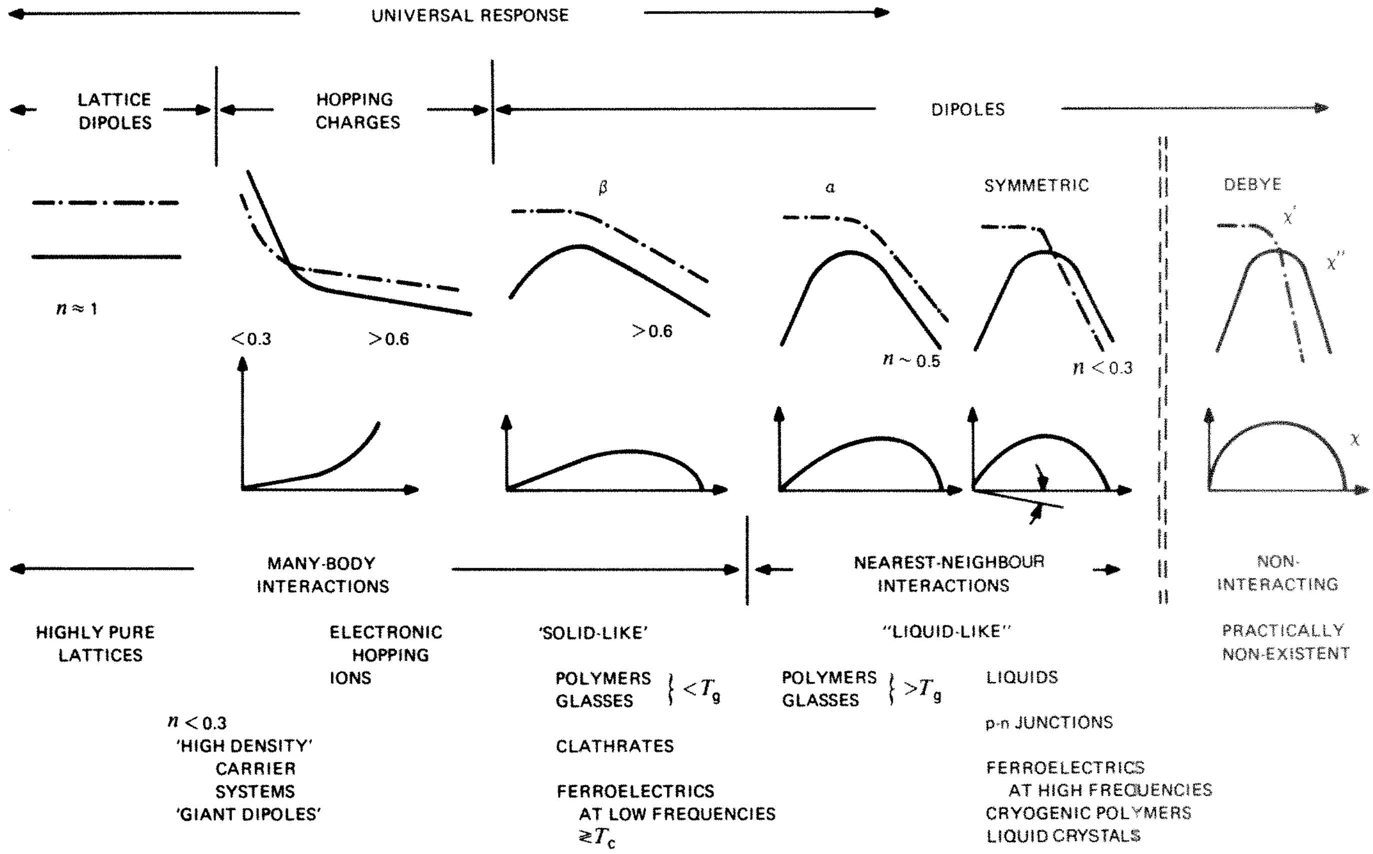

Fig. 1 A representation of the various observed types of dielectric response in the entire range of solids. The upper set of diagrams represent the shapes of the logarithmic plots of $\chi'(\omega)$ (chain–dotted lines) and $\chi''(\omega)$ (solid lines), ranging from the ideal Debye through the α and β peaks and on to the universal dependence for charged carrier systems. The limiting forms of behaviour are represented by the strong low-frequency dispersion with small values of n and by the limiting case of frequency-independent 'lattice response' with $n \approx 1$. The lower set of diagrams represents the corresponding complex χ plots. The various types of materials obeying the respective types are shown and the presumed polarisation mechanisms are indicated. For further details and source references see ref. 4.

is, < 10 GHz) we are particularly interested in the $\Delta E = |T_{12}| \rightarrow 0$ limit. It has been argued by Anderson[15], that T_{12} being a complex matrix element acts like the x and y components of the random field, as it has real and imaginary parts. The probability that the mode energy ΔE lies in the interval $|T|$ and $|T| + d|T|$ is then proportional to $|T|d|T|$. Thus, the density of states of very low energy, tunnelling modes, $N(\Delta E)$, is proportional to ΔE. Now the sudden potential change that induces transitions between the two alternate levels should on the whole not depend on ΔE. Thus, within this class of tunnelling modes, the condition for IR divergence $|V_{12}|^2 N(\Delta E) = n\Delta E$ is satisfied and the universal law follows for spin-glasses. Note that here, and henceforth, (unless otherwise stated) the two states of the TMs are considered thermodynamically accessible to each other. The possible role of thermodynamically inaccessible correlated states in contributing to the divergent dielectric response will be pointed out later. Also note that quite generally systems describable, for example, by a random Hubbard model would be expected to exhibit magnetic properties describable in terms of spin glass states with an example being perhaps impurity bands in crystalline semiconductors.

(2) Dielectrics with atom–atom or molecule–molecule or ion–ion or dipole–dipole interactions: spin–spin interaction models can often be transcribed to other physical models with non-spin interactions[17]. Well known examples include the Ising model equivalence to a lattice gas and to a binary alloy. A lattice gas is a collection of atoms (molecules) whose positions can take on only discrete values which form a lattice. Each lattice site can be occupied by at most one atom. In general the potential energy of the system of atoms corresponds to a gas in which the atoms are located only on lattice sites and interact through a two-body potential $v(|\mathbf{r}_i - \mathbf{r}_j|)$. The correspondence between the lattice gas and the Ising model is then practically immediate[18].

Consider dielectrics were atom–atom, molecule–molecule or ion–ion interactions are important. In the 'lattice' gas and/or binary alloy modelling of dielectrics with random interactions, the essential equivalence to the spin glass Ising model implies that a dielectric state corresponding to the spin glass state exists. Such dielectrics will have, in analogy to spin glasses, very low energy tunnelling modes which correspond to the change of the atomic (molecular or ionic) occupancy of several sites in getting from one energy minimum to the other. This class of tunnelling modes again should satisfy the criterion for IR divergence and hence yields the universal law. The lattice gas and binary alloy model should be good representations of many dielectrics including the class of solid state ionic conductors[19,20] or solid electrolytes such as AgI, CaF and Na β-alumina. In fact, ionic conductivity for these solids has been calculated in the lattice gas model[21]. In the case of Na β-alumina, there is the repulsive interaction among the diffusing sodium ions and also the attractive interactions between the ions and their randomly distributed, compensating defects. These properties imply a lattice gas with random interactions. There is ample experimental evidence[22,23] for the existence of tunnelling modes in alkali β-alumina as well as Ag β-alumina. In particular there is an excess low temperature specific heat[23,24] contribution just as in the case of the spin glasses.

(3) Dielectrics with electron self-trapping states: the concept of local electron self-trapping largely arises from the observation that by and large if a particular electronic state is singly occupied the atom or atoms principally associated with this state will adjust their positions in such a way as to lower the energy level of this state relative to its value when unoccupied. A traditional example is provided by those ionic solids where strong local coulomb interactions between the electron and lattice constituents induces a local lattice distortion leading possibly to

the self-trapping of the electron and the formation of a small polaron. This tendency is not simply restricted to ionic materials but is much more general. Well known examples lying outside the usual small polaron mechanism are provided by the reconstruction of semiconductor surfaces[25,26] and electron pairing states in amorphous glasses[27,28]. The origin of the self-trapping in these instances is essentially a dehybridisation energy[25,26,29,30] arising from concepts inherent in covalency and stereochemistry. The electron–lattice interaction may be strong enough to make it energetically much more favourable to self-trap electrons in pairs rather than singly and such systems have been described by Anderson[27] through a negative U Hubbard model. Let us restrict our attention for the moment to the negative U electron pairing states which should be the physically most important due to the prevalence of diamagnetic systems in nature. in this instance several subgroups of possible correlated states can be identified with properties leading to the desired behaviour in χ'' where, in each case, the response time of these states is expected to be acceptably slow due to the lattice coordinates involved.

Consider first those systems where there are a continuous density of pairing states, the number of which exceeds the number of available electrons. In these instances one can envision very low energy TMs corresponding to different arrangements of the electrons over the pairing centres. By direct analogy with the spin glass TMs these electron-pair TMs should exhibit the desired properties; that is $N(\Delta E)\propto\Delta E$, $V(E)=$ constant.

Another not completely orthogonal subgroup of bipolaron derived TMs that could contribute to the ω^{n-1} behaviour of χ'' is realised when the system is such that bipolaron states are essentially degenerate with, for example, non-distortive extended states. Furthermore, in those instances where the coulomb repulsion dominates, heavily favouring single self-trapping of the electron, various subgroups of correlated states can be identified which are completely analogous to the bipolaron ones outlined above. Intermediate subgroups can also be defined where, for example, one envisages very low energy excitations which entail disassociation of a bipolaron into two singly self-trapped electrons or vice versa.

Consider now an example of a thermodynamically inaccessible correlated state which could produce the desired functional dependence in χ''. For this purpose assume a smooth density of electron pairing states in the neighbourhood of the 'Fermi level' and suppose that a field induced hop of the polarisable species introduces a coupling between these states which is largely independent of energy. In this instance one will expect an ω^{n-1} dependence in χ'' from very low energy excitations that involve the transfer of an electron pair from an occupied to initially unoccupied pairing centre. This behaviour, however, will be completely smeared out at experimental temperatures unless we suppose that the energy barriers between pairing states is sufficient to prevent thermally assisted tunnelling. Thus the system at finite temperature is presumed locked into a metastable state and this could happen for large enough negative U. This case is complementary to our previous examples where it is supposed that each TM has equal probability of being in either of its two states. Note that the possibility of low lying excitations which are thermodynamically inaccessible over at least the time of a specific heat measurement has already been pointed out[15] and in amorphous materials metastable states may persist almost indefinitely. Furthermore in this metastable regime the response of the system should depend on its history.

Although in this section we have considered primarily amorphous systems where one expects an appreciable number of weaker/stronger bonds, lone pairs, and so on, to be present giving rise to the correlated states, it is also reasonable to expect that such low-lying excitations occur and are important in more nearly crystalline solids where, for example, the remaining pairing centres in these materials could partially pin the Fermi level in their vicinity. Another relevant point is the probable presence of an appreciable density of correlated states at various interfaces such as oxide–semiconductor[29], and metal–semiconductor[30]. Thus, although interface or contact effects are usually ignored, we expect that such systems should also exhibit a dielectric loss obeying the 'universal law' and a systematic study of the details could provide a powerful probe of the interfacial structure, so important in device physics.

Low frequency IR divergent dielectric response

Having argued that dielectrics with diverse interaction types should have invariably some very low frequency excitations that contribute a time dependence of the form t^{-n} at large t to some correlation function, we examine further the properties of the dielectric response function. Here we focus on the behaviour of $\chi''(\omega)$ starting several decades above any associated loss peak that may exist, since this is the region where the universal ω^{n-1} dependence is found (see Fig. 1). In doing this we do not exclude those dielectrics which have associated with them the presence of charge carriers of an electronic or an ionic nature. In this regime the dielectric loss is simply related to the probability of exciting the correlated states and is given by $\chi''(\omega)\propto \int_{-\infty}^{+\infty} \mathrm{d}t\, \mathrm{e}^{i\omega t} e^{-\phi(t)}$ where $\phi(t)$ describes the time response of the correlated states due to the sudden potential, V. The function $\phi(t)$ has been obtained many times[7,8] and in our notation takes the form $\phi(t)\equiv\int_0^{E_c} V^2N(E)\,(1-e^{-iEt})\,(dE/E^2)$. The existence of some class of correlated states in the dielectric with $V^2N(E)\equiv nE$ produces an IR divergence in the number of low energy correlated states excited and for large E_ct, $\phi(t)$ can be approximated by $n\ln(iE_ct)$. Putting this result back into the expression for χ'' leads immediately to the universal law $\chi''(\omega)\propto\omega^{(n-1)}$. Note that the loss peak observed in dipolar solids before the universal response can be accommodated as well within the present framework and will be discussed elsewhere. In addition, dielectrics with hopping electronic or ionic charge carriers would be expected to show a strong low-frequency dispersion, in accordance with experimental evidence.

Conclusions

We have arrived at a fundamental mechanism for the universal dependence of the dielectric loss in nearly all dielectrics at frequencies above any loss peak that may be present and the mechanism is operative independent of the physical structure and chemical bonding in the materials. We emphasise the importance here of not only the identification of the Curie–von Schweidler law as an IR divergence phenomenon but also the subtle task of finding the correlated state excitations that are responsible for it.

The entire empirically determined range of values of the exponent, $0<n<1$, can be accounted for in the present theory depending on the values of the exciting potential V arising from the transitions of the charged species and of the density of states of correlated state excitations. The appearance of the limiting form of the Debye response may be expected in situations where V or $N(E)$ are negligible. Our approach then produces a general scheme for classification of dielectrics based on the type of dominant correlations and correlated states they render. In particular, a discussion of correlated states associated with electron–electron, electron–lattice, ion–ion correlations as well as various subgrouping have been given. There may still be other types of correlations leading to correlated states with the same properties. In any event, dielectric loss should provde a powerful probe into details of the correlated states of the type we have considered here. We acknowledge financial support from the NSF and SRC.

Correlation of the Eemian (interglacial) Stage and the deep-sea oxygen-isotope stratigraphy

Jan Mangerud, Eivind Sønstegaard & Hans-Petter Sejrup

Department of Geology, Allégt. 41, 5014 Bergen-Universitetet, Norway

A complete interglacial sequence in coastal marine sediments in western Norway is correlated with the Eemian Stage by means of pollen stratigraphy, and with deep-sea cores by means of marine fossils. The Eemian is correlated with isotope stage 5e.

THE correlation of deep-sea and continental records is one of the most important problems in Quaternary stratigraphy. Because nearly all cores from the deep-sea floor can be correlated using the $^{18}O/^{16}O$ record[1,2], oxygen-isotope stratigraphy is also the most valuable method of correlation with the continents. The general principles in the correlation of glacial/interglacial periods with oxygen-isotope stages are known[1]. However, the correlation of real stratigraphical units defined on land, and the oxygen-isotope stages remains problematic beyond the range of ^{14}C dating.

Here we correlate the Eemian Stage of North-west Europe with the oxygen-isotope stage 5e as follows: a complete interglacial sequence in coastal marine sediments in western Norway can be correlated with the Eemian by means of its pollen stratigraphy, and the marine fauna of the same section can be correlated with the biostratigraphy of cores from the Norwegian Sea[3], in which the oxygen-isotope stratigraphy has also been established[4,5].

Shakleton[6] first argued for the correlation of 5e with the Eemian, and his conclusion has been accepted by most scientists. Confirmation has, however, been lacking, and discussion of alternative correlations has continued. Off the Pacific coast of North America the correlation of 5e with the forest vegetation period of the last interglacial has been demonstrated[7].

Definition and stratigraphical position of the Eemian

The Eem interglacial is now generally accepted as a chronostratigraphical unit with stage rank: the Eemian Stage[8-10]. The type locality is along the river Eem, near Amersfoort, Netherlands[11]. The lower boundary is defined as where a subarctic park landscape at the type locality is replaced with a closed forest and the upper boundary is placed where the forest at the type locality is replaced by a more open vegetation.

The Eemian in North-west Europe is clearly recognisable by its typical pollen stratigraphy[12,13]. This approach could create confusion if the vegetational development during two interglacials were very similar. However, this does not seem to be a serious problem for the Eemian.

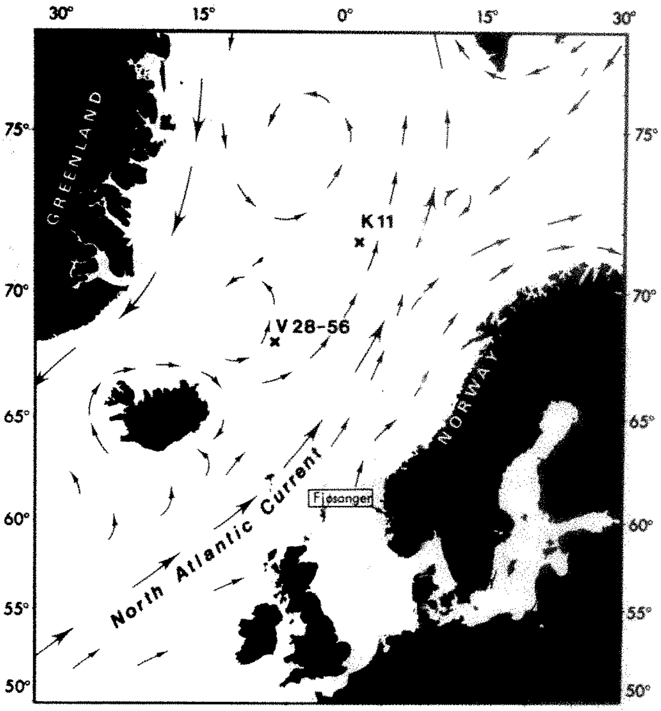

Fig. 1 Map of the Norwegian Sea and surrounding areas. The location of Fjøsanger and the cores mentioned in the text are indicated. The oceanic surface currents are also shown.

0028-0836/79/0277—0189$01.00

Until recently it had been agreed that the Weichselian Stage immediately followed the Eemian. As the type area for the Weichsel glaciation is in Poland, some correlations are, however, necessary for this interpretation. It is also clear that glaciers reached Poland only during parts of the corresponding chronostratigraphical unit, the Weichselian Stage. If the Weichselian follows the Eemian, the type locality for the Eemian would also be the best boundary stratotype for the Eemian–Weichselian Stage boundary, and it has been used as such for a considerable time. We accept this definition based on the abundant evidence from North-west Europe for this sequence. Woillard[14] has suggested, however, that interglacials exist between the Eemian and the Weichselian. She carried out thorough studies of the most complete pollen sequence through the Upper Pleistocene in western Europe, the Grand Pile, France, and recognised that the Eemian was succeeded by two warm periods which she defined as interglacials St Germain I and II. The lower (St Germain I) is further divided into two warm phases, with a short cooling between.

St Germain I and II can be correlated with the Early Weichselian interstadials, the Amersfoort, Brørup[11,15] and Odderade[16]. The arguments for this correlation are: (1) their stratigraphical positions immediately above the Eemian are identical. (2) The vegetation during the St Germain I and II indicates a colder climate than does the Eemian vegetation at the same site. (3) Considering the southern location (47° 44′ N) of the Grand Pile, it is possible to correlate the vegetation during the St Germain I and II with the vegetation in North-west Europe during Amersfoort, Brørup and Odderade.

To avoid any confusion which may arise if the above statements about the Eemian and Weichselian should be shown to be erroneous, we have defined local chronostratigraphical units, which we subsequently correlate with the Eemian and the Weichselian (Fig. 2).

The Fjøsanger Interglacial, and its correlation with the Eemian

The Fjøsanger locality is situated along the shore of a small fiord, just outside the city of Bergen, western Norway (Fig. 1). Preliminary descriptions of the section have already been given[17,18], and a detailed description will be published else-

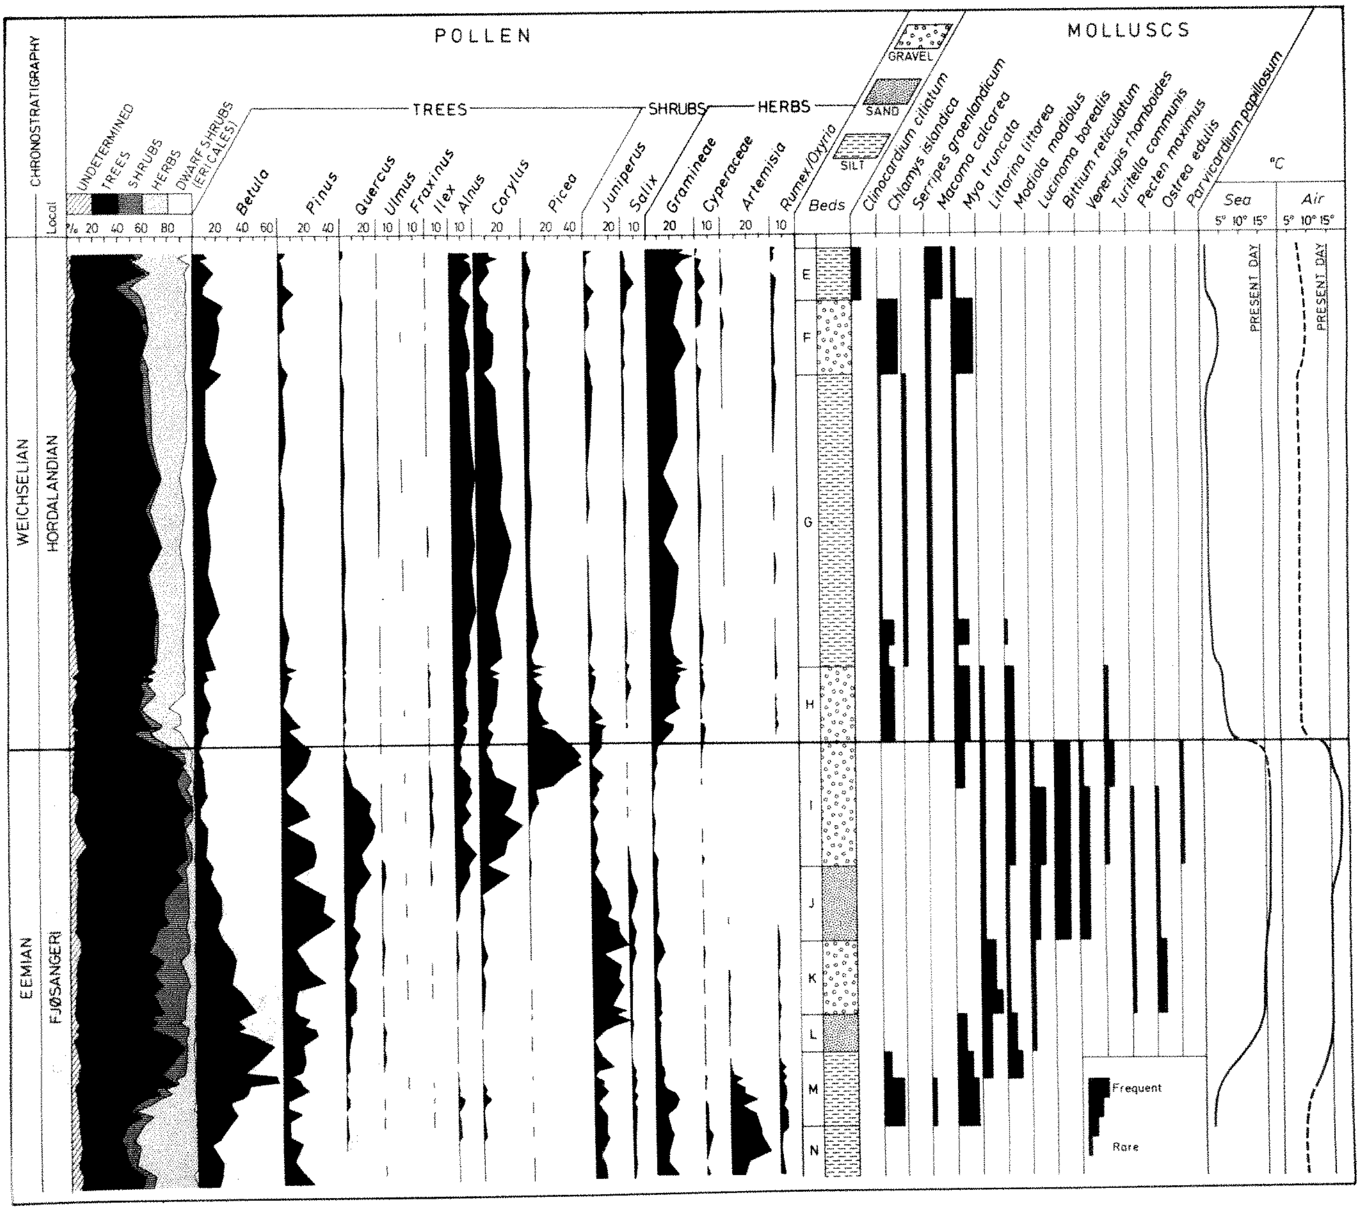

Fig. 2 The stratigraphy of the Fjøsanger site. The lithology of the beds is simplified and only the most important species of pollen and molluscs are shown. The temperature curves indicate mean air and sea temperatures for the warmest months, July and August respectively. The atmosphere curve is deduced from pollen data, the sea curve from molluscs and benthic foraminifera.

where. Two till horizons are located at the base of the sequence. Above these follows a sequence of marine sediments (beds N–E, Fig. 2), deposited in a fiord at depths of between 10 and 50 m during an interglacial and the earliest part of the following glacial period. The sediments consist of silt, sand and gravel (Fig. 2). However, even the coarse-grained sediments have a matrix of clay and silt, and both the benthic foraminifera and the pollen stratigraphy support an interpretation of continuous deposition of the clay–silt fraction throughout the marine sequence. The section is capped by a till.

We (in preparation) have defined the Fjøsangerian Stage with a lower boundary at the base of bed N (Fig. 2) and an upper boundary between beds I and H. The latter is also the lower boundary for the Hordalandian Stage.

The main criterion for the correlation of the Fjøsangerian Stage with the Eemian is the pollen stratigraphy (Fig. 2), the most significant features of which are: (1) the very distinct successional phases. (2) Early immigration of *Quercus*. (3) Development of a dense *Quercus–Corylus* forest, with very sparse occurrence of other QM-constituents. (4) *Alnus* increased at the same level as *Corylus*. (5) Late immigration of *Picea*, with a peak very late in the interglacial. The only main feature of the Eemian which is lacking is the *Carpinus* phase, which is almost certainly due to the northerly latitude of the Fjøsanger locality. The vegetation during the deposition of gravel I, indicates a mean summer temperature slightly higher than at present (Fig. 2).

At the type locality, the lower boundary for the Eemian Stage is placed at a horizon when a closed forest was established[12]. By comparison with the Holocene vegetational development it may be assumed that the spread of *Betula* woodland at Fjøsanger took place slightly later than at the type locality in the Netherlands. Actually, Fjøsanger was still covered by ice at the Weichselian–Holocene boundary. Bearing this in mind, we have placed the lower boundary for the Eemian immediately after the deglaciation of the site, and we assume that the error in this time correlation should not exceed some few hundred years.

We have correlated the Eemian–Weichselian boundary with the Fjøsangerian–Hordalandian boundary where the NAP-pollen increases from ~5% to 30%. This clearly represents a complete deforestation of the area, and we assume that all tree pollen types above this level, except possibly some *Betula*, are redeposited.

The molluscs and benthic foraminifera lead to very similar conclusions, and therefore only the mollusc diagram is presented here (Fig. 2). The fauna indicates cold polar water in the lower part of the Eemian (silt M, Fig. 2) and thereafter a rapid increase in temperature due to the appearance of the Atlantic Current. In beds I and J the fauna indicates warmer water than along the coast today, and also species not known from Norwegian waters were (for example, *Parvicardium papillosum*). As some of the mulluscspecimens are only referred to bed I, and the benthic foraminifera indicate a shallowing during the deposition of the upper part of this bed, it is difficult to detect a possible fall in temperature during the deposition of the upper part of bed I, but this must in any case have been very modest. From the deposition of bed I to that of bed H a drastic fall in temperature occurred, but the influence of the Atlantic Current is still detectable. In silt G, a polar fauna dominated, and during the deposition of this bed, glaciers were calving in the fiord. The fauna in gravel F indicates that the glaciers had retreated and this bed is assumed to correspond to an interstadial. Silt E represents another glaciomarine facies, above which the till follows. Whether or not a hiatus exists below the till is impossible to determine.

Three features of the Fjøsanger section are of major importance for correlation with the Norwegian Sea stratigraphy: (1) an oceanic circulation pattern similar to that of the present was established in the lower part of the Eemian. (2) During most of the Eemian, coastal waters were as warm, or warmer, than at present. (3) A drastic cooling of the sea water occurred at the Eemian–Weichselian boundary.

Correlation with the deep-sea record

Kellogg[3,19] studied cores from the Norwegian Sea. Mainly by means of two faunal indices (Fig. 3), he has shown that only once during the past 450,000 yr has the surface water of the Norwegian Sea been as warm, or warmer, than during the Holocene.

The $^{18}O/^{16}O$ ratio has been measured in two of the cores from the Norwegian Sea, and one core from the Denmark Straight[4,5]. The younger oxygen-isotope stages used in the world ocean stratigraphy were clearly recognised in these cores (Fig. 3).

The dominant factor determining the surface temperature of the sea both in the eastern Norwegian Sea and along the coast of Norway is the Atlantic Current. From a theoretical point of view, it is clear that faunas from the Norwegian coast, and the surface of the eastern Norwegian Sea, can be correlated by means of their temperature requirements. This is in accordance with knowledge of the present-day zoogeography, and also with geological correlations of the major change in the current pattern 10,000–13,000 yr ago[20–23].

The 'warm pulse' described by Kellogg can therefore be unambiguously correlated with the warm-water phase at Fjøsanger. The warm pulse in the Norwegian Sea appears at the same level as the oxygen-isotope stage 5e. As the warm-water phase at Fjøsanger occurred within the Eemian, the Eemian Stage can be correlated with the oxygen-isotope stage 5e.

Concerning a more precise correlation of the boundaries, the 6–5e boundary in the cores V 28–56 and K-11 (Fig. 3) is

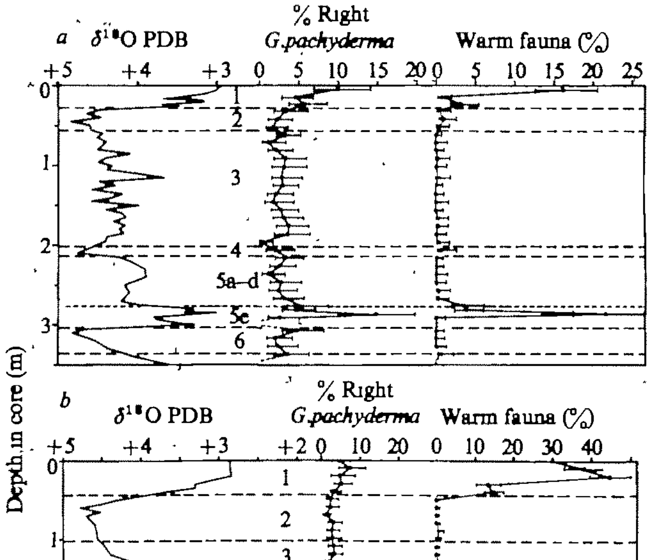

Fig. 3 The stratigraphy of two Norwegian-Sea cores (Fig. 1): *a*, K-11; *b*, V 28–56; according to Kellogg, Duplessy and Shackleton[4]. The curves represent (from the left): the $^{18}O/^{16}O$ curve; the oxygen-isotope stages (numbers), % right-coiling species (warm) of *Globigerina pachyderma*; and % warm-water foraminifera species.

significantly below the warm pulse. At Fjøsanger there is also a cold fauna in the lower Eemian. We have deduced, however, a high sedimentation rate for this part of the stratigraphy, and thus a short time period. This would indicate that the lower boundary for the Eemian is slightly above the 6–5e boundary.

In the cores from the Norwegian Sea (Fig. 3), the upper boundary of the warm pulse is very close to the 5e–5d boundary. At Fjøsanger the dramatic cooling of the seawater also occurred at the Eemian–Weichselian boundary, indicating that the Eemian–Weichselian boundary is nearly synchronous with the 5e–5d boundary.

These correlations are also supported by sea-level data from the North Sea area, for which Zagwijn[24] has given the best data. A major part of the transgression took place within the Eemian, indicating that the Eemian started long before the peak of the ^{18}O/^{16}O curve. Around the Eemian–Weichselian boundary, Zagwijn[24] found a drop in sea level of 32 m, of which half took place within the Eemian. Compared with the ^{18}O/^{16}O sea-level curve derived by Shackleton and Opdyke[1], this suggests that the Eemian–Weichselian and the 5e–5d boundaries are synchronous.

The sea-level data are also a very stong argument, independent of the main theme of this paper, that the Eemian should be correlated with 5e, and not a larger, or other part of stage 5.

The onset of the last glaciation

The forests at Fjøsanger during the later part of the Eemian indicate a climate which excluded the growth of any large ice-masses in Scandinavia. The drop in sea level during the Eemian thus indicates that the growth of ice sheets started earlier in North America and/or Antarctica than in Scandinavia.

At Fjøsanger the glaciomarine silt G (Fig. 2) confirms that glaciers approached Bergen early in the Weichselian. From the present day topography and climate, one can conclude that these first glaciers descended from mountains in the vicinity, and were not outlets from an inland-ice. These glaciers retreated at least once (bed F, Fig. 2) before Fjøsanger was covered by ice.

The vegetational succession during the upper part of the Eemian indicates, in our opinion, a climatic deterioration. However, the drastic fall in temperature at Fjøsanger occurred simultaneously in the sea and on land at the Eemian–Weichselian boundary. There can be no doubt that the cause of the sudden cooling was a weakening of the flow of the Atlantic Current into the Norwegian Sea. If the Atlantic Current was 'switched off' the sequence described would result, whether or not this event was preceded by, or caused by, a climatic deterioration.

The radiometric age of the Eemian

From the ^{14}C isotope enrichment method, the age of the early Weichselian interstadials has been estimated as 55,000–70,000 yr BP[25], and the Eemian is commonly assumed to be slightly older.

Another approach is correlation with tropical coral reef terraces, dated with the U-series methods. Shackleton and Matthews[26] showed that the oxygen-isotope stage 5e can be correlated with the Barbados III terrace, dated to 125,000 yr BP. Accepting the correlation of 5e with the Eemian, this age should also apply to the Eemian.

There is a significant discrepancy in the results from the two methods. At present we find the U-series ages most probable.

We thank Dr N. J. Shackleton and K. Bjørklund for helpful criticisms and Dr B. Robins for correcting the English. The project was supported by grants from The Royal Council for Scientific and Industrial Research and The Norwegian Research Council for Science and Humanities.

Nucleotide sequence of a region of human mitochondrial DNA containing the precisely identified origin of replication

Stephen Crews, Deanna Ojala, James Posakony, Jerry Nishiguchi & Giuseppe Attardi

Division of Biology, California Institute of Technology, Pasadena, California 91125

A fragment of HeLa cell mitochondrial DNA containing the origin of replication has been sequenced. The precise position of the origin in this sequence has been identified by determining the nucleotide order in the 5′-end proximal portion of the heavy strand initiation fragment (7S DNA), and by aligning the two sequences.

MITOCHONDRIAL DNA synthesis in animal cells has been shown to have very distinctive features. In mouse L cells, where this process has been studied in most detail, DNA replication starts at a site located near the 5′-end of the 12S rRNA coding sequences with the displacement synthesis of a daughter H-strand, which grows in the direction away from the rRNA genes. When the nascent H-strand is at least two-thirds complete, synthesis of the complementary L-strand DNA begins at a point

0028–0836/79/0277—0192$01.00

approximately 67% of the genome length from the H-strand origin, proceeding in the opposite direction, and ultimately replication is completed[1,2]. The same type of asymmetrical replication of mit-DNA has been observed in other animal cell systems such as HeLa cells, chick embryo, chick liver, rat liver, *Xenopus* cells and sea urchin oocytes[3]. However, the degree of asynchrony in the replication of the two strands varies considerably between different systems and also in the same system. Furthermore, in most systems investigated, including rat liver and rat hepatoma cells[4], sea urchin oocytes[5], *Drosophila melanogaster*[6] and HeLa cells (D. Carré and G. A., unpublished observations), a varying, though generally small, proportion of mit-DNA molecules has been observed to undergo a synchronous unidirectional replication of the two strands, resulting in totally duplex replication forms. The significance and possible regulation of this variability in the degree of asynchrony between displacement synthesis and complement synthesis in mit-DNA replication are unknown.

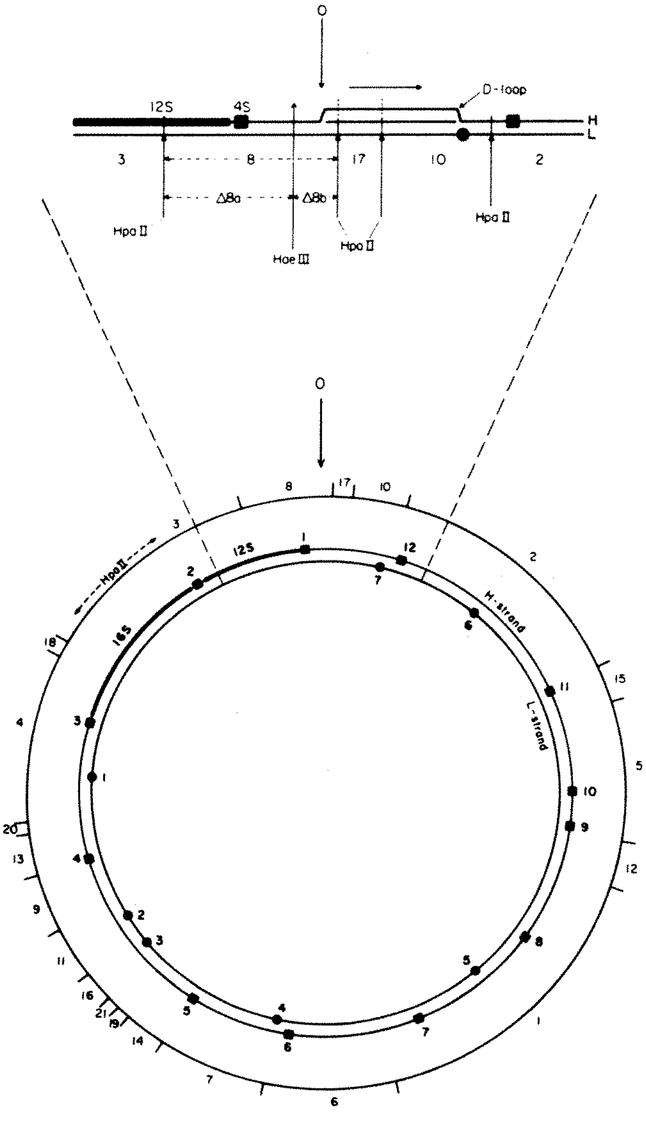

Fig. 1 Physical and genetic maps of HeLa cell mit-DNA. The restriction endonuclease map determined with the enzyme *Hpa*II[12] has been aligned with the *Eco*RI and *Hin*dIII maps[14] and with the map of the positions of the complementary sequences for the 12S and 16S rRNA on the H-strand and for 4S RNAs on the H(■) and L strands (●)[15]. In the upper part, a region of the *Hpa*II physical map of HeLa cell mit-DNA has been expanded to show the precise positions of the origin of replication (vertical arrow [marked O]) and of the D-loop. The rightward arrow indicates the direction of H-strand synthesis. H: heavy strand; L: light strand. The arrows marked *Hpa*II indicate *Hpa*II cleavage sites; the arrow marked *Hae*III indicates an *Hae*III site in *Hpa*II fragment 8 (modified from D.O. and G.A.[13]).

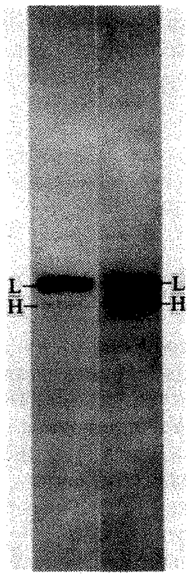

Fig. 2 Autoradiograph of the separated strands of 5′-end labelled fragment $\Delta 8b^{Hae}$. The restriction fragment $\Delta 8b^{Hae}$ was obtained by cleaving purified *Hpa*II fragment 8 with *Hae*III and electrophoresis of the digestion products on a 1.5% agarose gel in 0.032 M Tris, 0.02 M sodium acetate, 0.002 M EDTA, *p*H 7.4, for 4 h at 4 V cm^{-1}. The fragment was eluted by diffusion at 37 °C in 0.001 M Tris-HCl. *p*H 7.4, 0.001 M EDTA. In the left track, fragment $\Delta 8b^{Hae}$ was labelled, without prior dephosphorylation, with [γ-^{32}P]ATP and T4 polynucleotide kinase (PL Biochemicals) using the exchange reaction. In the right track, $\Delta 8b^{Hae}$ was dephosphorylated with 4 μg of bacterial alkaline phosphatase (Worthington BAPF) in 100 μl of 0.01 M Tris-HCl, *p*H 8.0, at 37 °C for 1 h (freed of divalent cations by treatment with BioRad Chelex 100)[19]. The phosphatase was removed by extraction with phenol–chloroform–isoamyl alcohol (50:50:1), or inactivated by the addition of nitrilotriacetic acid to 0.005 M at 25 °C[20]. The dephosphorylated 5′-ends were 'kinased' by the procedure described by Maxam and Gilbert[16], which included a heat denaturation step in the presence of 0.001 M spermidine. The labelled fragments were denatured in 0.001 M Tris-HCl, *p*H 7.4, 0.001 M EDTA for 5 min at 90 °C, quickly cooled in an ice bath and, after addition of a Ficoll–bromphenol blue mixture, electrophoresed on a 6% polyacrylamide (1 : 30 bisacrylamide) gel in 0.05 M Tris-borate, *p*H 8.3, 0.001 M EDTA. The gel was run at 4 °C for 15 h at 6 Vcm^{-1}. The two separated strands were excised from the gel and eluted by diffusion at 37 °C in 0.5 M ammonium acetate, 0.1% SDS, 10^{-4} M EDTA. In later experiments, *Hpa*II fragment 8 was cleaved with *Hae*III, and the products were directly kinased and subjected to strand separation as above.

Equally unique to mit-DNA of most animal cells investigated so far is the presence, in a substantial portion of the molecules, of a displacement loop (D-loop) near the origin of replication. This loop results from the synthesis of a short segment of H-strand DNA which displaces the parental H-strand[7]. These single-strand segments of DNA (referred to as 7S DNA because of their sedimentation coefficient in sucrose gradients) have recently been shown to exist as discrete size classes ranging between 500 and 700 nucleotides depending on the cell type. In mouse L cells, most of the 7S DNA molecules have a common 5′-end with a variability in length at the 3′-end[8], whereas, in human cells, the variability has been reported to be at the 5′-end[9] or at both ends[8]. In L cells there also seems to be a microheterogeneity at the 5′-end of each predominant size class[8]. Recent studies have shown that the 7S DNA is unstable, with a half life of about 1 h in L cells[10] and 2.8 h in human KB cells (D. Bogenhagen and D. Clayton, personal communication). Therefore, if 7S DNA is a primer for DNA replication, only a small fraction of the 7S DNA molecules can serve this role, as mit-DNA is known to be stable. The true function(s) of 7S DNA is still unknown. It may reflect a need for the cell to be able to recognise the origin or to continuously expose the single-stranded parental H-strand for initiation of transcription. Conceivably also, the D-loop may be involved in the recently discovered interaction between the mitochondrial inner membrane and the origin of mitochondrial DNA replication[11].

This article describes a sequence analysis of the region surrounding the origin of mit-DNA replication in HeLA cells. In these cells, by electron microscopic mapping of the D-loop with respect to certain restriction enzyme cutting sites, the origin of mit-DNA replication had been previously located in one of the three *Hpa*II fragments, 8, 10 or 17 (ref. 12). More recently, by using 7S DNA as a template for fragment-primed DNA synthesis by *Escherichia coli* DNA polymerase I and by carrying out a polyacrylamide gel electrophoretic analysis of the *in vitro* products after restriction enzyme cleavage, it has been possible to localise the position of the 5′-end of the 7S DNA in *Hpa*II fragment 8, at about 80 nucleotides from the *Hpa*II cutting site between fragments 8 and 17 (ref. 13). It has been further shown that *Hpa*II fragment 8 can be subcleaved by *Hae*III into two smaller fragments designated as $\Delta 8a^{Hae}$ (~560 base pairs) and

$\Delta 8b^{Hae}$ (~200 base pairs), and that the origin is contained in $\Delta 8b^{Hae}$ (ref. 13). This information, summarised in Fig. 1, has thus provided the foundation for the sequencing work described here.

Sequence analysis of the region of mit-DNA containing the origin of replication

The approach followed here to sequence the region of mit-DNA around the origin of replication involved isolating the restriction fragment $\Delta 8b^{Hae}$, labelling the 5′-ends with [γ-^{32}P]ATP and T4 polynucleotide kinase, separating the strands and sequencing both strands by the technique of Maxam and Gilbert[16]. As the fragment $\Delta 8b^{Hae}$ was known to be around 200 nucleotides long, we hoped that by ordering more than 100 nucleotides from each end, we could sequence the entire fragment with a substantial sequence overlap. Fragment $\Delta 8b^{Hae}$ was isolated by gel electrophoresis, eluted and subjected to two kinds of kinase reactions: (1) the exchange reaction[17,18], which does not require prior dephosphorylation of the 5′-terminus of the DNA, and (2) removal of the 5′-phosphate with bacterial alkaline phosphatase and then treatment with polynucleotide kinase[16]. Figure 2 shows the results of the kinase reactions on strand separation on a polyacrylamide gel. Significantly, in the DNA labelled by the exchange reaction, the faster migrating band contained only 15% as much radioactivity as the slower moving band, whereas DNA labelled after dephosphorylation revealed a faster migrating band labelled to the extent of about 65% of the slower band. As the incorporation into the slower migrating band was similar in the material labelled by the two procedures, in the present work, the DNA was routinely dephosphorylated before treatment with polynucleotide kinase.

After elution of the material in the two labelled DNA bands, aliquots of each sample were hybridised to an excess of either the heavy or the light strand of HeLa cell mit-DNA, incubated with S_1 nuclease, and the acid precipitability measured. The DNA from the faster migrating band hybridised to the extent of about 56% of the input c.p.m. to the H-strand and of 2% to the L-strand, whereas about 42% of the input c.p.m. in the material from the slower migrating band hybridised to the L-strand and 0.6% to the H-strand. The lack of complete hybridisation to mit-DNA of the two separated Δ8b strands is presumably due to the occurrence of some breaking at the ends of the hybrids, with the S_1 nuclease cleaving off a portion (40–50%) of the 5′-labelled nucleotides. On the basis of these data, we have designated the faster migrating DNA strand, $\Delta 8b^{Hae}(H)$, and the slower migrating DNA strand, $\Delta 8b^{Hae}$(L). It is not clear why the dephosphorylated and kinased $\Delta 8b^{Hae}$(H) contained a lower amount of radioactivity than $\Delta 8b^{Hae}$(L) (varying, in different experiments between 75% and 31%). This difference is probably due to incomplete dephosphorylation, or to renaturation and subsequent lower incorporation during kinase treatment at the flush end created by the *Hae*III enzyme relative to the staggered 5′-end produced by *Hpa*II, or to some other feature, such as secondary structure.

Sequence analysis of the labelled DNA strands was carried out by the Maxam and Gilbert procedure[16], using the G > A, A > C, C+T and C reactions. The sequence of nucleotides 2 to 25 was determined by fractionating the cleavage products on a 25% polyacrylamide–7 M urea gel; nucleotides 26 to 148 for $\Delta 8b^{Hae}$(L) and nucleotides 25 to 123 for $\Delta 8b^{Hae}$(H) were identified by fractionating the reaction products on 10% polyacrylamide–7 M urea gels (Fig. 3). The total length of the fragment was found to be 221 nucleotides, and thus it was possible to obtain an approximately 50 nucleotide overlap.

To complete the sequence, the end-labelled separated strands were digested exhaustively with endonuclease P_1, which generates 5′-mononucleotides[21], and the products were separated by one-dimensional chromatography on thin layer polyethylenimine strips. The results shown in Table 1 indicate that the 5′-terminal nucleotide of both the H and L strands is dCMP, as expected for the *Hpa*II and *Hae*III cutting sites. The complete sequence of the fragment $\Delta 8b^{Hae}$ is shown in Fig. 4.

In situ	2	5	3	89	ND	1	1	ND

5′-end-labelled $\Delta 8b^{Hae}$(L) and $\Delta 8b^{Hae}$(H) were dissolved in 15 μl 50 mM ammonium acetate, pH 5.4, and digested with 1 μg P_1 endonuclease from *Penicillium citrinum* for 1 h at 37 °C[21]. After addition of 10 nmol each of 5′-dAMP, dCMP, dGMP and dTMP, the mixture was applied to a PEI cellulose thin layer strip. After washing the strip in methanol, one-dimensional thin layer chromatography was carried out using 1 M acetic acid for 2 cm and then 1 M acetic acid–3 M LiCl(9 : 1) for 16 cm[22]. 7S DNA, with 15 μg of yeast tRNA carrier, was dissolved in 15 μl 50 mM ammonium acetate, pH 5.4. The mixture was digested with 2.5 μg of P_1 at 37 °C for 3 h. After addition of marker 5′-dNMPs, the digest was spotted onto a PEI cellulose plate and run in the first dimension as above. The plate was washed successively with Tris–methanol and methanol, and then run in a second dimension for 16 cm using 6 g $Na_2B_4O_7 \cdot 10H_2O$, 3 g H_3BO_3 and 25 ml ethylene glycol in 70 ml water[22]. All thin layer plates were examined by autoradiography sensitive enough to detect 1% of the input radioactivity (3 d.p.m. in a 1-mm^2 circle), and then the marker spots were visualised with a short-wave UV lamp and the spots cut out. They were eluted quantitatively with 1 ml of 0.02 M Tris-HCl, pH 7.4, 0.7 M $MgCl_2$ and counted in 10 ml of a Triton–xylene based scintillation fluid. ND, not detectable.

* The values refer to the radioactivity which migrated from the origin. The % of the input radioactivity recovered from the origin was, respectively, 0.5 and 4.9% for $\Delta 8b^{Hae}$(L) and $\Delta 8b^{Hae}$(H), not detectable and 1.2% for isolated 7S DNA (experiments 1 and 2, respectively) and 2.0% for the *in situ* labelled 7S DNA

Isolation and characterisation of 7S DNA

To precisely localise the origin of mitochondrial DNA replication in the $\Delta 8b^{Hae}$ fragment, the approach followed was to sequence the 5′-end portion of the 7S DNA and to align this sequence with that of $\Delta 8b^{Hae}$. Previous reports of 7S DNA size heterogeneity in human, mouse and other animal cells and also of an apparent 7S DNA 5′-end microheterogeneity in mouse L cells required that HeLa cell 7S DNA be first characterised in its size and 5′-termini.

Isolation of 7S DNA was carried out by the procedure of Kasamatsu *et al.*[7], in which the 7S DNA molecules are released from closed circular mit-DNA by brief heat treatment and then separated by sucrose gradient centrifugation. The material in the 7S DNA peak was further purified from RNA contaminants by RNase digestion or nitrocellulose chromatography[23], and then isolated by polyacrylamide or agarose gel electrophoresis in denaturing conditions.

Figure 5 illustrates the purification procedures used. Slot 2 shows the pattern obtained by electrophoresing through a 4% polyacrylamide–7M urea gel a sample of sucrose gradient-isolated 7S DNA labelled *in vitro* at the 5′-end with [γ-^{32}P]ATP and T4 polynucleotide kinase. A prominent band (indicated as 1) is seen migrating at a position corresponding to a length of about 680 nucleotides (estimated by comparison with marker HeLa cell *Hpa*II fragments). A fainter band (indicated as 2), corresponding to a size of about 630 nucleotides, can also be seen. The further purification achieved by nitrocellulose chromatography is shown in slot 3, where the discrete and heterogeneous components visible in the lower part of the gel and presumably arising from RNA contaminants have been

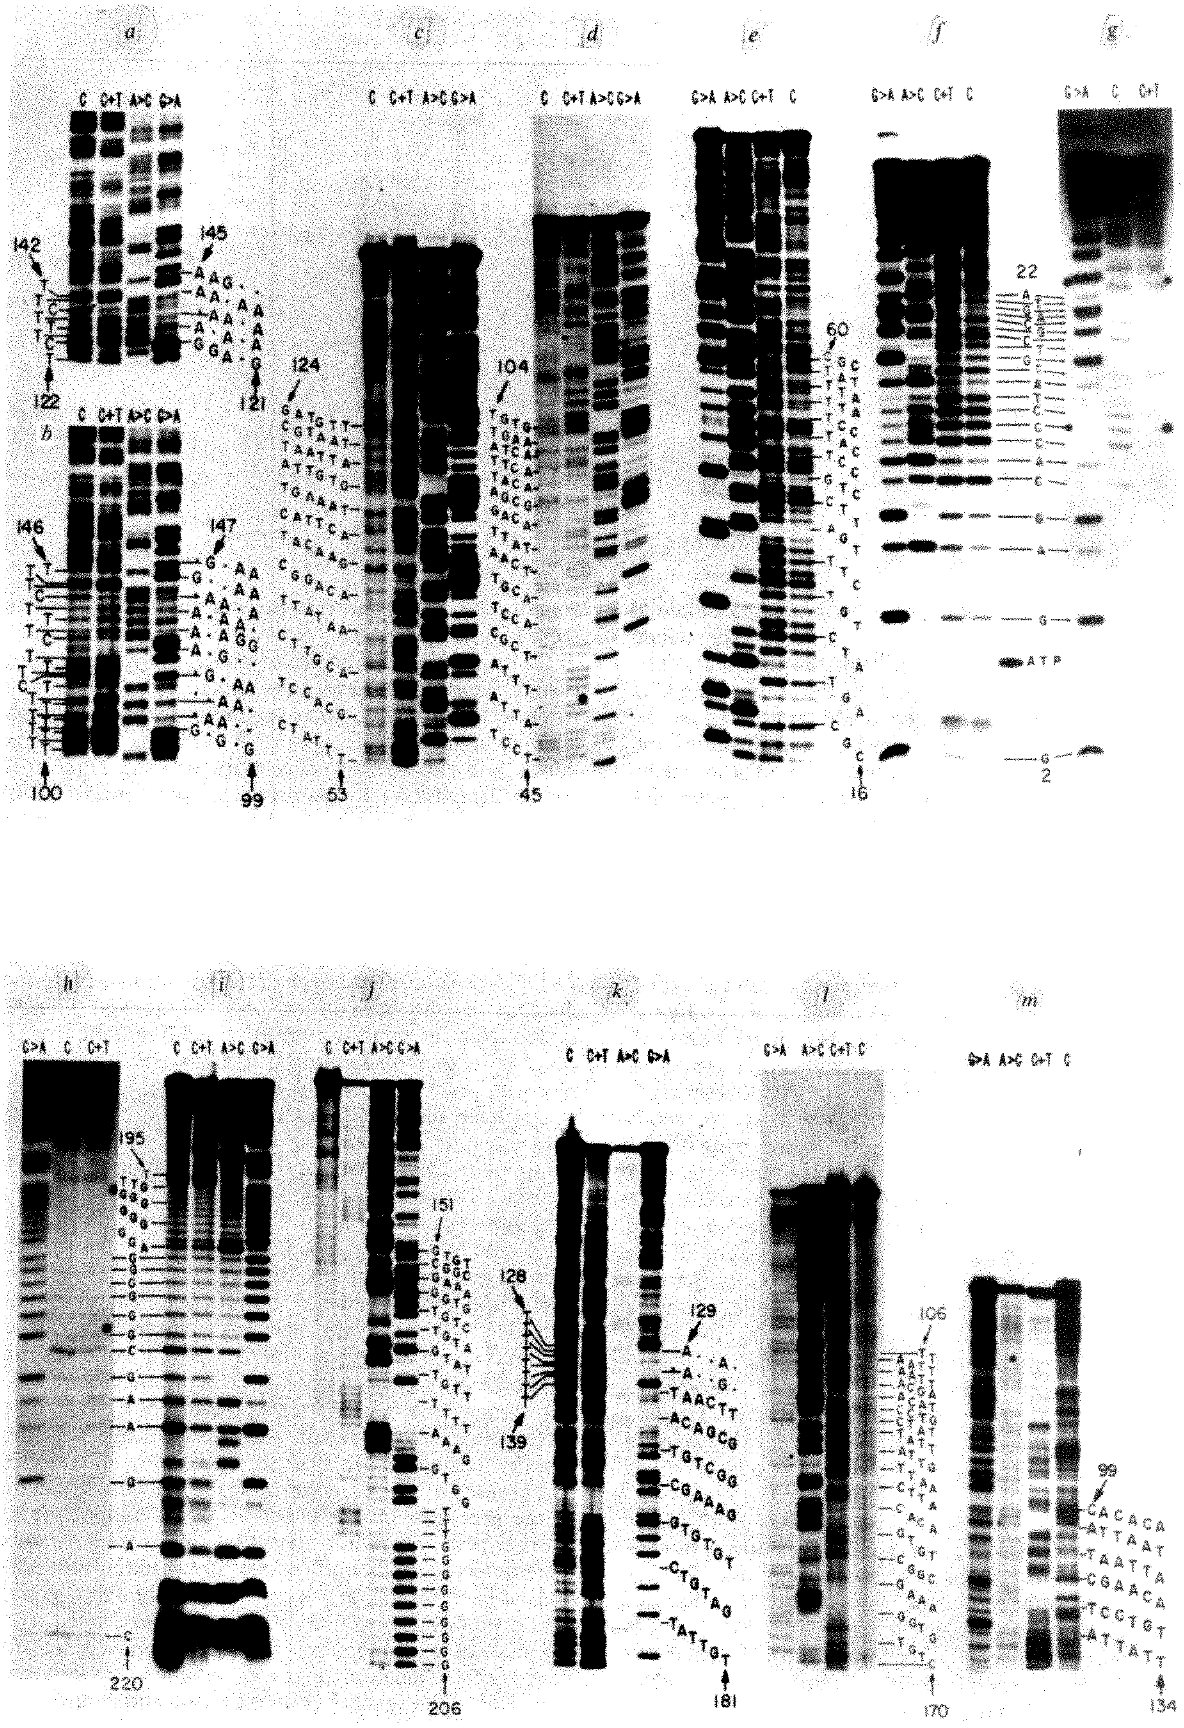

Fig. 3 Representative autoradiographs of sequencing gels of $\Delta 8b^{Hae}$(L) (*a–g*) and $\Delta 8b^{Hae}$(H) (*h–m*). The DNA strands, labelled at the 5′-end with [γ-^{32}P]ATP and polynucleotide kinase after alkaline phosphatase treatment (see text), were sequenced using the chemical methods of Maxam and Gilbert. The sequence reactions used and the times of reaction for the base modification step were G > A (10 min), A > C (10 min), G + T (15 min) and C (15 min). The degradation products were electrophoresed at 1,000 V for *a*, 15.5; *b*, 13; *m*, 12; *c*, *l*, 8.5; *d*, *k*, 7.25, *f–i*, 7 and *e*, *j*, 4 h on either 10% polyacrylamide (1 : 20 bisacrylamide)–7 M urea gels (*a–e*, *j–m*) or 25% polyacrylamide (1 : 30 bisacrylamide)–7 M urea gels (*f–i*) (40 × 30 × 0.15 cm) in 0.05 M Tris-borate, *p*H 8.3, 0.001 M EDTA, that had been pre-electrophoresed for 2 and 3 h, respectively, at 900 V. The gels were wrapped with Saran wrap and exposed at −70 °C using pre-fogged Kodak X-Omat XR-5 film with a DuPont Cronex Lightning-Plus intensifying screen.

Fig. 4 Nucleotide sequence of the fragment $\Delta 8b^{Hae}$ and of the 5'-terminal segment of 7S DNA.

eliminated. Slot 4 shows the electrophoretic pattern obtained with 7S DNA prepared, using the isolation procedure described above, from cells labelled *in vivo* with ^{32}P-orthophosphate. The pattern observed is very similar to that of the *in vitro* labelled material. Here, in addition to the two above mentioned bands, there is also a third faint band migrating at a position corresponding to a size of about 590 nucleotides. These observations on *in vivo* labelled material indicate that the appearance of the minor 7S DNA components is not due to artefacts introduced by the *in vitro* labelling conditions.

Comparison of the electrophoretic patterns of sucrose gradient-purified 7S DNA with those published by Brown *et al.*[9] and Gillum and Clayton[8] suggests that the major and the minor bands observed here correspond to the three major forms of 7S DNA detected by these authors in several human cell types. However, the relative intensities of the bands observed by the cited authors and those shown here are strikingly different. Instead of three components in approximately equal amounts, our material shows a preponderance of the largest, 680 nucleotide long, component. To exclude the possibility that this difference resulted from losses or degradation occurring during purification of the 7S DNA, the *in situ* labelling technique used by Gillum and Clayton[8] was followed. In this procedure, the 7S DNA is labelled without prior separation from closed circular mit-DNA. In Fig. 5, slot 5, where the results of this experiment are presented, the electrophoretic pattern seen is very similar to that of the *in vitro* labelled samples with the 680 nucleotide long component again being strongly predominant. Densitometric analysis of these autoradiograms indicate that this component represents 70–80% of the total 7S DNA in preparations labelled *in situ*, and more than 95% in preparations labelled after sucrose gradient isolation, assuming equal efficiency of *in vitro* labelling of the various components.

The fact that the relative intensities of the bands produced by the two labelling methods were comparable did not rule out the possibility that the difference in mobility between the 7S DNA components might be due to some factor other than heterogeneity in length. However, treatment with RNase (Fig. 5, slot 4) or pronase (in the presence of SDS) before electrophoresis failed to alter the observed number, relative abundance, or electrophoretic mobility of these components, thereby excluding any possible role of a covalently linked RNA primer or of DNA-associated protein in generating this phenomenon. In addition, when the *in situ* labelled component 2 and the *in vitro* labelled component 1 were isolated from the urea gel, heat denatured and re-run through a second urea gel in the same conditions (Fig. 5, slots 6 and 7, respectively), or through an agarose–CH_3HgOH gel[26] (not shown), they maintained the same relative electrophoretic mobility. The above results support the conclusion that the multiple bands arise from discrete length differences.

To investigate the possibility of 5'-end microheterogeneity (which would not have been detected by the above electrophoretic analysis), sucrose-gradient-isolated 7S DNA was labelled at the 5'-end with [γ-^{32}P]ATP and T4 polynucleotide kinase and subjected to digestion with the *Hpa*II restriction enzyme. (*Hpa*II is known to cleave single-stranded DNA[27], and previous experiments in this laboratory had indicated that the *Hpa*II site present in the single stranded portion of the D-loop (which is equivalent in sequences to the 7S DNA) is cut at a low frequency in standard digestion conditions[13].) The digest was analysed on a 7.5% polyacrylamide–7M urea gel; the results obtained (not shown) indicated that a small percentage of the 7S DNA molecules had been cut at a position corresponding to a distance of ~86 nucleotides from the labelled 5'-end (as estimated from the migration of the small fragment thus produced relative to that of denatured ΦX174 RF DNA *Hae*III fragments)[28]. As the resolving power of the gel electrophoresis used would have shown a difference of 1 or 2 bases in length, the above results indicate that the 5'-end of the main 7S DNA component occurs at a unique position within the mitochondrial genome. To obtain further evidence on this question, a 5'-end base analysis was carried out. 7S DNA was dephosphorylated at the 5'-end by alkaline phosphatase either *in situ* or *in vitro* after sucrose gradient isolation, labelled with [γ-^{32}P]ATP and polynucleotide kinase, purified by nitrocellulose chromatography and electrophoresed through a 4% acrylamide–7M urea gel. The main component was eluted from the gel and subjected to digestion with endonuclease P_1. The products were analysed by two-dimensional chromatography on polyethylenimine thin layer plates, and the results are given in Table 1. In the *in vitro* labelled sample, more than 90% of the counts recovered are represented by dTMP, confirming the conclusion that the 5'-end of the predominant HeLa cell 7S DNA component is unique. Furthermore, no radioactivity, or only traces of radioactivity, were detected in ribonucleotides. The results obtained for the *in situ* labelled sample are very similar, although a slightly larger proportion of radioactivity seems to be associated with deoxyribonucleotides other than dTMP; this may reflect the lower degree of purification of *in situ* labelled 7S DNA due to the omission of the sucrose gradient purification step.

Sequence analysis of 7S DNA

The main 7S DNA component was subjected to alkaline phosphatase treatment and the kinase reaction either *in situ* or after sucrose gradient purification, passed through a nitrocellulose column and then run on a polyacrylamide–urea gel. After elution of the 7S DNA from the gel, it was submitted to the Maxam–Gilbert sequencing reactions.

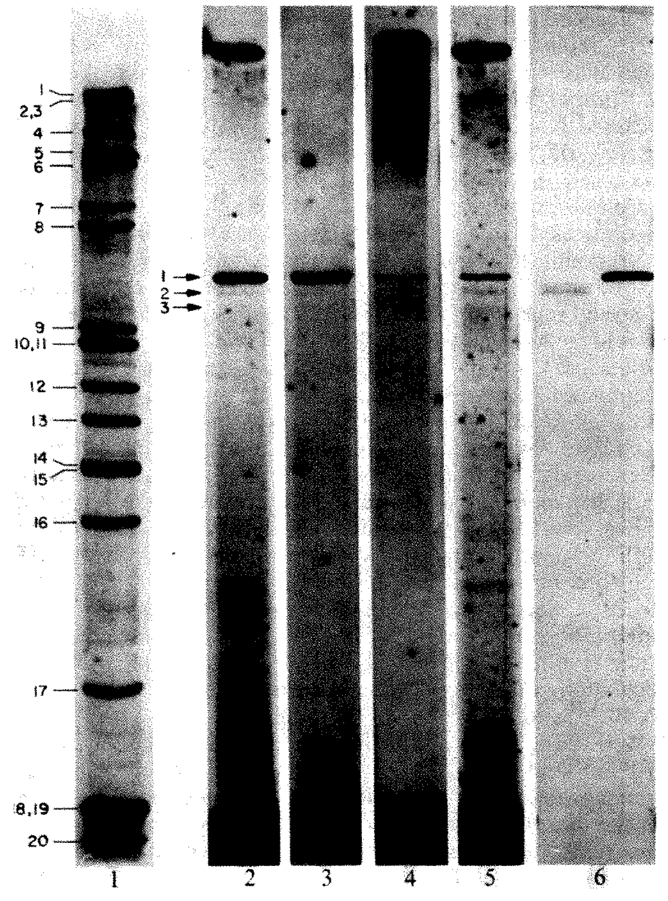

Fig. 5 Autoradiographs, after electrophoresis through 4% polyacrylamide–7 M urea gels, of HeLa cell 7S DNA labelled *in vitro* or *in vivo* and purified in different ways. All samples, in 0.001 M Tris-HCl, *p*H 7.4, 0.001 M EDTA, were adjusted to 6 M urea, heated at 100 °C for 1 min and loaded on a 4% polyacrylamide (1 : 30 bisacrylamide)–7 M urea slab gel. Electrophoresis was carried out at 5 V cm^{-1} for 15 h. *Slot 1*: *Hpa*II digest of HeLa cell mit-DNA labelled *in vitro* with [α-^{32}P]dNTP and *E. coli* DNA polymerase I[12]. *Slots 2 and 3*: 7S DNA was released from mit-DNA by brief heating, isolated by sucrose gradient centrifugation[7], and labelled *in vitro* at the 5′-end as follows: A sample of ~0.2 pmol of 7S DNA (estimated by assuming a proportion of about 10% D-loop containing molecules in HeLa cell mit-DNA preparations[24], and a complete recovery of the isolated 7S DNA) was dephosphorylated and 5′-end labelled as described in Fig. 2 legend. After ethanol precipitation, the pellet was dissolved in 0.001 M Tris-HCl, *p*H 7.4, 0.001 M EDTA. A portion of the sample was analysed directly (slot 2) and a portion was further purified by nitrocellulose (NC) chromatography. For this the sample (50 μl) was adjusted to 0.5 M KCl and passed through a 1.5 × 0.3 cm nitrocellulose column (Hercules, prepared as described by Boezi and Armstrong[25]) equilibrated with 0.5 M KCl, 0.01 M Tris-HCl, *p*H 7.4. The column was washed with equilibration buffer to remove all the unbound radioactivity, then eluted with 0.001 M Tris-HCl, *p*H 7.4, 0.001 M EDTA (slot 3). *Slot 4*: 7S DNA from 1.5×10^{8} cells labelled *in vivo* with ^{32}P-orthophosphate[12] was isolated by sucrose gradient centrifugation and run on gel after treatment with pancreatic RNase (40 μg ml^{-1}, 10 min at 25 °C). *Slot 5*: 7S DNA labelled *in situ* following the procedure of Gillum and Clayton[8]: a sample of 10 μg mit-DNA in 100 μl 0.01 M Tris-HCl, *p*H 8.5, 0.01 M NaCl, was incubated with 0.05 μg calf intestine alkaline phosphatase (Boehringer Mannheim) for 1 h at 57 °C, and then labelled with [γ-^{32}P]ATP and T4 polynucleotide kinase. *Slots 6 and 7*: 7S DNA components 2 and 1, which had been labelled at the 5′-end *in situ* or after sucrose gradient isolation, respectively, then purified by nitrocellulose chromatography, and run through a 4% polyacrylamide–7 M urea gel, were eluted and rerun in the same conditions.

Figure 6 shows a sequencing gel of 5′-end labelled, sucrose gradient-purified 7S DNA. A sequence of around 25 nucleotides could be determined unambiguously. This sequence is identical to the portion of the sequence of $\Delta8\mathrm{b}^{Hae}$(H) from residue 87 to residue 63. This alignment allowed the positioning of the 5′-end of 7S DNA to correspond with residue 87 of $\Delta8\mathrm{b}^{Hae}$. Sequencing experiments using *in situ* labelled 7S DNA gave identical results[28].

Discussion

In the experiments reported here, we have precisely located the origin of HeLa cell mit-DNA synthesis in the *Hpa*II map of this DNA and examined the sequence surrounding it. The location of the 5′-end of the 7S DNA, determined by sequence analysis to be at 87 nucleotides from the *Hpa*II cutting site between fragments 8 and 17, is in excellent agreement with the 7S DNA priming experiments that indicated the origin to be at approximately 80 nucleotides from the *Hpa*II site, and with the experiments in which 5′-end labelled 7S DNA was cut with *Hpa*II giving a labelled DNA fragment about 86 nucleotides long. The size of $\Delta8\mathrm{b}^{Hae}$ is 221 nucleotide pairs, which is about 10% longer than the value that was earlier derived from its electrophoretic mobility in agarose gels relative to that of *Hpa*II fragments.

There are several interesting features of the $\Delta8\mathrm{b}^{Hae}$ sequence (Fig. 4), although their significance is unclear. Beginning at nucleotide 215 and proceeding clockwise (the clockwise direction is here defined as the direction of H-strand synthesis), there is a stretch of 17 G·C base pairs in a row with an A·T pair interruption at position 207. Furthermore, there is a strong purine bias on the H-strand. Nearby, from position 189 to 181, there is a stretch of 9 A·T base pairs in succession. There is another A·T base pair stretch running from position 137 to 128, and, contained within it, an 8 nucleotide true palindrome from position 137 to 130. Closer to the origin is a 13 A·T base pair stretch which contains two true palindromes (113–104 and 116–105) and a sequence with a twofold axis of symmetry (115–104). Repeated sequences are relatively rare; the sequence $\begin{matrix}5'\,\mathrm{TTGTTAT}\,3'\\3'\,\mathrm{AACAATA}\,5'\end{matrix}$ at nucleotides 140–134 is repeated at positions 182–176, and the sequence $\begin{matrix}5'\,\mathrm{GTGGAAA}\,3'\\3'\,\mathrm{CACCTTT}\,5'\end{matrix}$ is found at nucleotides 166–160 and at 193–187. The sequence

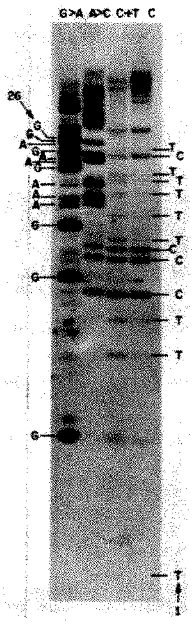

Fig. 6 Representative autoradiograph of 7S DNA sequencing gel. Sucrose gradient isolated 7S DNA was dephosphorylated and 5′-end labelled, as detailed in Fig. 2 legend, purified by nitrocellulose chromatography and then run through a 4% polyacrylamide–7 M urea gel. The main component (1) was eluted and subjected to the sequencing reactions G > A, A > C, C + T and C. Due to the low amount of radioactivity in the 7S DNA preparations, the base modification reactions were carried out for a time 10 times longer than used for the $\Delta8\mathrm{b}^{Hae}$ strands (legend to Fig. 3). This extended reaction time resulted in a decreased mobility of the products in the A > C reaction. The cleavage products were electrophoresed on a 25% polyacrylamide–7 M urea gel for 6.3 h.

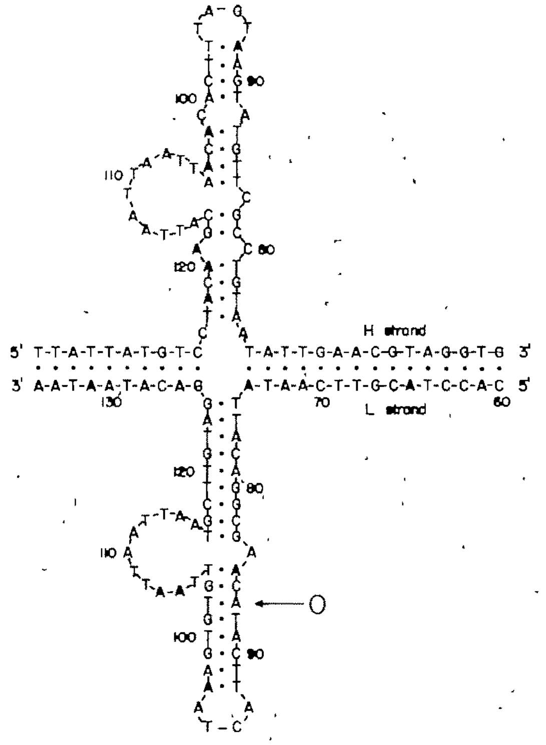

Fig. 7 Possible secondary structure of the region of fragment $\Delta 8b^{Hae}$ surrounding the origin of replication. The arrow (O) points to the nucleotide in the L-strand which is complementary to the 5′-end nucleotide of 7S DNA. The ΔG values of the L-strand and of the H-strand portions of the structure were calculated on the basis of the thermodynamic data for Watson–Crick nearest-neighbour sequences, loops, mismatches, and G·U pairs, as compiled for ribonucleic acids (see text) The free energies of base-pair addition were reduced by about 15% whenever the base-pair doublet included a G·C pair, in order to correct for the greater stability of the rG·rC pair as compared to dG·dC[34] In view of the many assumptions underlying these calculations, the ΔG values reported in the text have to be considered only as rough indicators of stability.

$$\begin{matrix}5'\,\mathrm{TATGATG}\,3'\\3'\,\mathrm{ATACTAC}\,5'\end{matrix}$$, often found to be associated with promoter sites[29], is located at nucleotides 178 to 172 and might possibly be associated with an L-strand promoter site.

The origin itself is preceded, going in a clockwise direction, by a 29-nucleotide long A·T rich region that extends 3 nucleotides past the origin, is followed by a 6-nucleotide G·C rich region and then by a 10-nucleotide long A·T rich region. A·T rich sequences have previously been noted near other origins of DNA replications; however, we do not detect any sequence characteristics in common with the other origins of replication and primer RNA–DNA junctions that have been accurately localised (ColE1[30] RNA–DNA junction, ΦX174 viral strand origin[31], fD[32] and G4 complementary strand[33] origins) nor with the L-cell 7S DNA sequence[8].

Computer analysis of the sequence data indicates a theoretically stable hairpin structure that could form when the DNA double helix is unwound, as occurs during DNA synthesis. As shown in Fig. 7, this looped structure contains the origin of H-strand replication and an interior A·T rich loop, 12 nucleotides long. As calculated using the rules of Tinoco *et al.*[35,36] and Gralla and Crothers[37], the ΔG of the L-strand hairpin structure is approximately $-13\ \mathrm{kcal\ mol^{-1}}$ and that of the H-strand hairpin is approximately $-5\ \mathrm{kcal\ mol^{-1}}$, with the difference being due to two A·C pair mismatches in the H-strand stem. Although this secondary structure is probably thermodynamically stable at 25 °C in a moderate ionic strength buffer at neutral *p*H, it is not known whether it is ever formed *in vivo*. However, the presence of the origin in the hairpin at only two nucleotides from the A·T rich interior loop is suggestive of a functional role for this structure. Secondary structure loops have been strongly implicated in the initiation of phage fD[32] and G4[33] complementary strand synthesis, and may be involved in the initiation and regulation of DNA replication in the mammalian papovaviruses SV40[38,39] and BKV[40].

We have not detected any ribonucleotides covalently attached to the 5′-end of the 7S DNA that might represent an RNA primer or residues of it. Clayton *et al.*[8] have presented evidence for the presence of an RNA primer in mouse L cell 7S DNA. The reason for this difference is unknown. In HeLa cell 7S DNA, we have also observed a greater homogeneity in size than previously reported in 7S DNA from other human cell types and other organisms. Nor have we detected the 5′-end microheterogeneity described in these systems. Our sequence analysis has not revealed any repetition of sequence or other structural features that might point to the existence of multiple initiation points, thereby explaining the existence of the multiple size classes. Instead, we think that the discrete size classes and the relative amounts of 7S DNA contained in each of them, the 5′-end microheterogeneity and the presence of RNA primer residues may reflect various rates or pathways of 7S DNA processing which could be dependent on cell type and/or physiological conditions.

This work was supported by NIH grants GM-11726 and ST32GM-07616. We thank A. Chomyn for the computer analysis of the DNA sequence, A. Maxam and W. Gilbert for advice on sequence determination, N. Davidson for valuable discussions and A. Drew for technical assistance.

Upper limits for γ-ray bursts from primordial black holes

PAGE AND HAWKING[1] have predicted that primordial black holes of mass $\sim 10^{15}$ g will evaporate, reaching an explosive stage at a mass which depends on the nuclear processes occurring. For the composite particle model 10^{34} erg of γ rays will be produced at energies of 100–1,000 Mev. For the elementary particle model 10^{30} γ rays of energy 5×10^{12} eV are expected. We have already set upper limits[2,3] for the rate of primordial black hole explosions in the Galaxy assuming the composite particle model. We report here upper limits from two other sets of data, assuming the elementary particle model and using the atmospheric Cerenkov technique as before.

In the first data set the Mt Hopkins 10-m reflector[4] was used with a field of view of 1°. Approximately 112 h of observation were analysed. As the detector has an energy threshold of 10^{11} eV it will respond to 5×10^{12} eV primaries over a large area. Events were recorded on analogue magnetic tapes together with a standard frequency and time markers. They were analysed by reconstituting the standard frequency with a phase-locked loop, and after scaling, deriving a 0.1 s clock signal. The number of events recorded in each successive 0.1 s interval was determined with a mini-computer and a distribution derived. The characteristic signature of a γ-ray burst would be a group of individual showers occurring together within 0.1 s.

At five points in the data bursts were observed which were incompatible with random Poisson expectation. Four of these were very large and had durations of 2–11 s. They were probably local in character and due to man-made interference. The fifth event was just above the burst threshold (12 showers) and lasted 0.1 s. Without a distant coincident detector this event could not be ascribed to a cosmic origin. We therefore derived an upper limit at the 99% confidence level of 6.1 events in 112 h, or 477 events yr^{-1}.

The collection area of showers of 5×10^{12} eV was estimated at 5×10^{9} cm^2 and the solid angle was taken conservatively at the geometric value of 2.4×10^{-4} sr. Twelve showers were required for a detectable burst, corresponding to 96 erg and giving a sensitivity of 1.9×10^{-8} erg cm^{-2}. The maximum detectable distance r is then given by $4\pi r^2 = 8\times10^{30}/1.9\times10^{-8}\ \text{cm}^2$, hence $r = 5.7\times10^{18}$ cm $= 1.9$ pc. The sensitive volume $V = \Omega r^3/3 = 5.5\times10^{-4}\ \text{pc}^3$. The upper limit for the explosion rate is then 8.7×10^{5} explosions $\text{pc}^{-3}\ \text{yr}^{-1}$.

In the second data set[5] two 1.5-m reflectors were used in coincidence aligned parallel to each other at varying zenith angles. The full field of view was 5°; 78 h of observation were obtained. The normal counting rate was about 300 showers min^{-1} at the zenith. The energy threshold for the system was 3×10^{12} eV and the collection area for 5×10^{12} eV γ-rays estimated at $3\times10^{9}\ \text{cm}^2$. Events were recorded on analogue magnetic tape as before.

No groups of events were recorded beyond Poisson expectation. Seven events would be required for a statistically detectable burst, corresponding at 5×10^{12} eV to 56 erg and giving a sensitivity of 1.8×10^{-8} erg cm^{-2}. The maximum detectable distance r is then given by $4\pi r^2 = 8\times10^{30}/1.8\times10^{-8}\ \text{cm}^2$ hence $r = 5.9\times10^{18}$ cm $= 2.0$ pc. The sensitive volume $V = \Omega r^3/3 = 1.6\times10^{-2}\ \text{pc}^3$. The upper limit at the 99% confidence level for zero bursts observed is 4.3 bursts in 78 h or 483 yr^{-1}. The upper limit for the explosion rate is then 3.0×10^{4} explosions $\text{pc}^{-3}\ \text{yr}^{-1}$.

Using particle detectors at sea level with a higher energy threshold, which required some assumptions about the primordial black hole emission spectrum, Fegan *et al.*[6] have found lower limits than those reported here. A further improvement in the Cerenkov method would require the use of one or more detectors with considerably larger collection area, and if possible, a wider field of view. A limit of about 1 explosion $\text{pc}^{-3}\ \text{yr}^{-1}$ is set irrespective of the nuclear model assumed, by observations of the isotropic γ-ray spectrum[1]. While the limit set with the Cerenkov technique assuming the composite particle model is only 4×10^{-2} explosions $\text{pc}^{-3}\ \text{yr}^{-1}$ (ref. 3), it seems likely that Cerenkov, particle, or satellite γ-ray detectors will probably not produce limits lower than about 10^{3} explosions $\text{pc}^{-3}\ \text{yr}^{-1}$ when the elementary particle model is assumed.

A non-singular quantum Universe

CLASSICAL relativistic singularities remain one of the most puzzling problems of contemporary physics. Although no consensus of opinion has been attained on their status, a great deal of work has been devoted to the search for physical mechanisms capable of eliminating the cosmological singularities, whose existence follows from the theorems of Hawking and Penrose[1,2]. The alternative view that the initial singularity of big-bang models is essential for the coming into being of the Universe, has also been advocated[3,4]. Some suggestions of cosmological singularity avoidance have recently come to light, in the 'classical' quantum regime (from 10^{-43}–10^{-23} s) (refs 5–8) or even without resorting to quantum effects[9]. The quantum gravitational period ($t < 10^{-43}$ s) remains potentially very interesting for searching for singularity avoidance mechanisms. An interesting approach is that of quantum cosmology, based on the hamiltonian formulation of general relativity (Dirac's[10] or Arnowitt, Deser and Misner's[11] (ADM) method). This approach was initiated by De Witt[12] and then followed by Misner[13] and many others (see refs 14,15) and is used here to derive a non-singular quantum cosmological model.

Much of the work done in quantum cosmology has been concerned with empty models. De Witt[12], however, in his particles treatment of a closed Friedmann Robertson-Walker (FRW) Universe, introduced a cloud of dust particles to support this metric. The initial singularity is avoided artificially in this model by postulating the existence of an infinitely steep wall at $R = 0$, (R is the 'radius' of FRW Universe) to exclude negative values of R. This choice forces the quantum wave function of the Universe to be zero at $R = 0$.

Misner's[13] pioneering work about quantum vacuum homogeneous models (Bianchi I and IX Universes), based on the ADM formalism, shows that the quantum gravitational fluctuations offer these models no escape from the classical singularity. The same conclusion seems to be true for the Bianchi Universes filled with a perfect gas with an equation of state of the type $p = (\gamma - 1)\rho$ (p and ρ denote respectively the pressure and total density of matter and γ is a constant between 1 and 2) if the matter is described by Ryan's [14] lagrangian which introduces no additional dynamical degree of freedom for the perfect gas. (Units are chosen so that $c = 1$, $G = 1$ and $h/2\pi = 1$.)

On the other hand, Schutz[16,17] has built a hamiltonian theory of the relativistic perfect fluid, based on the velocity-potential version of perfect-fluid hydrodynamics of Seliger and Whitham[18]. Schutz's canonical formalism introduces as dynamical degrees of freedom for the fluid the velocity potentials.

Lund[19] has used Schutz's formalism to study the effects of quantum gravitational fluctuations on the final issue of collapse of balls of dust ($p = 0$) and on the singularity of a closed dust-filled FRW Universe. He has taken the time variable from the matter variables, while Ryan's[12] time coordinate was Misner's[13] gravitational degree of freedom Ω. Ryan's method leads to a Klein–Gordon type equation for the wave function of the Universe, with its well known difficulties of interpretation while Lund's choice of time leads, in the cases he has considered, to a Schrödinger-like equation amenable to a probability interpretation (see ref. 20). By imposing the requirement that the corresponding mini-superspace[20–22] be geodesically complete, Lund concludes that, in this formalism, there is no inevitable singularity.

However, this Schrödinger equation, in the case of the closed FRW model, cannot be analytically solved and there is no guarantee that the wave function becomes zero for $R = 0$, which would be the case if it were impossible to find the Universe in the singular state. (For another possible definition of the absence of singularity in a quantum cosmological model, see ref. 23).

Thus, as far as we know, there has been no convincing evidence in the framework of quantum cosmology that the classical singularity could be avoided, under the influence of quantum gravitational fluctuations[24].

We give here an example of a non-singular quantum cosmological model, the 'dust-filled' Bianchi I Universe, "a behavioural paradigm for all anisotropic cosmological models"[25], quantised following the ADM method and with Lund's choice of time coordinate. The advantage of this model is that it can be analytically solved. As regards the hypothesis of a null pressure, it corresponds to the soft equation of state resulting from the Hagedorn[26] composite particle picture and it can also represent a cold, low-entropy early Universe filled with non-interacting baryons[27,28].

We use for the flat three-space theory of the Bianchi I Universe, Misner's[13] form:

$$\begin{aligned} \mathrm{d}l^2 = R_0^2\,\mathrm{e}^{2\mu}\{&\exp[2(\beta_+ + 3^{1/2}\beta_-)](\mathrm{d}x^1)^2 \\ &+ \exp[2(\beta_+ - 3^{1/2}\beta_-)]\mathrm{d}x^2)^2 \\ &+ \exp[-4\beta_+](\mathrm{d}x^3)^2\} \end{aligned} \tag{1}$$

R_0 is a constant and μ, β_+ and β_- are functions only of a time coordinate to be determined; μ, β_+ and β_- will be considered as the dynamical degrees of freedom.

We choose for the canonically conjugate moments to the g_{ij}, that is π^{ij}, the following expressions

$$\begin{aligned} \pi^{11} = &\left\{\frac{1}{12}[\pi_+ + 3^{1/2}\pi_-] + \frac{\pi_\mu}{6}\right\} \\ &\times R_0^{-2}\,\mathrm{e}^{-2\mu}\exp[-2(\beta_+ + 3^{1/2}\beta_-)] \end{aligned} \tag{2a}$$

$$\begin{aligned} \pi^{22} = &\left\{\frac{1}{12}[\pi_+ - 3^{1/2}\pi_-] + \frac{\pi_\mu}{6}\right\} \\ &\times R_0^{-2}\,\mathrm{e}^{-2\mu}\exp[-2(\beta_+ - 3^{1/2}\beta_-)] \end{aligned} \tag{2b}$$

$$\pi^{33} = \left\{-\frac{\pi_+}{6} + \frac{\pi_\mu}{6}\right\} R_0^{-2}\,\mathrm{e}^{-2\mu}\,\mathrm{e}^{4\beta_+} \tag{2c}$$

where π_μ, π_+ and π_- are the momenta conjugate to μ, β_+ and β_-, respectively. The action for the gravitational field and the matter (dust) can then be written as

$$\begin{aligned} S = \pi \int &[\pi_\mu\dot{\mu} + \pi_+\dot{\beta}_+ + \pi_-\dot{\beta}_- + \mathrm{p}^\phi\dot{\phi} - N(\mathscr{H}_\mathrm{V}^0 + \mathscr{H}_\mathrm{M}^0) \\ &- N_\mathrm{i}(\mathscr{H}_\mathrm{V}^\mathrm{i} + \mathscr{H}_\mathrm{M}^\mathrm{i})]\,\mathrm{d}t \end{aligned} \tag{3}$$

$\mathscr{H}_\mathrm{V}^0$ and $\mathscr{H}_\mathrm{M}^0$ are respectively the super-hamiltonian constraints for the vacuum[19] and for dust[16,19]

$$\mathscr{H}_\mathrm{V}^0 = \frac{R_0^{-3}\,\mathrm{e}^{-3\mu}}{24}[\pi_+^2 + \pi_-^2 - \pi_\mu^2] \tag{4a}$$

$$\mathscr{H}_\mathrm{M}^0 = 16\pi g^{1/2} N^2 (u^0)^2 \rho_0 = -N(u^0)p^\phi \tag{4b}$$

where ϕ is the only Seliger–Whitham velocity potential different from zero in this case; it is related to the four-velocity vector u_ν by

$$u_\nu = h^{-1}\frac{\partial\phi}{\partial x^\nu} \tag{5}$$

where h is the specific enthalpy of the fluid:

$$h = \frac{\rho + p}{\rho_0} \tag{6}$$

ρ_0 denoting the rest-mass density; p^ϕ is the momentum canonically conjugate to ϕ and N and N_i, respectively, the ADM lapse and shift functions; g denotes the determinant of the covariant spatial metric tensor and the overdots, in equation (3), the derivation with respect to the time variable, t.

Due to the homogeneity property of the t = constant surfaces of Bianchi-type universes, the supermomentum constraints: $\mathscr{H}_\mathrm{V}^\mathrm{i} + \mathscr{H}_\mathrm{M}^\mathrm{i} = 0$ are automatically satisfied.

Lund's method consists in choosing as time variable, the velocity potential ϕ:

$$T(t) = -\phi(t) \tag{7}$$

and imposing, in the framework of the ADM method, the coordinate condition:

$$t = T = -\phi \tag{8}$$

Then, solving the constraint: $\mathscr{H}_\mathrm{V}^0 + \mathscr{H}_\mathrm{M}^0 = 0$ for p^ϕ, we get for equation (3)

$$S = \pi \int [\pi_\mu\dot{\mu} + \pi_+\dot{\beta}_+ + \pi_-\dot{\beta}_- - H_\mathrm{ADM}]\,\mathrm{d}t \tag{9}$$

where the ADM hamiltonian, H_ADM is given by

$$H_\mathrm{ADM} = p^\phi = \frac{R_0^{-3}\,\mathrm{e}^{-3\mu}}{24}[\pi_+^2 + \pi_-^2 - \pi_\mu^2] \tag{10}$$

To quantise this model, we have to be careful: the usual choice of operators[14] corresponding to the classical conjugate momenta, for instance $\hat{\pi}_\mu = (1/i)(\partial/\partial\mu)$ is not appropriate here, as it would lead to a non-self-adjoint hamiltonian operator. However, if we introduce the canonical transformation

$$\begin{aligned} x &= 4(\tfrac{2}{3})^{1/2}\,\mathrm{e}^{3\mu/2} \\ \pi_x &= \tfrac{1}{4}(\tfrac{2}{3})^{1/2}\,\mathrm{e}^{3\mu/2}\pi_\mu \end{aligned} \tag{11}$$

the following hamiltonian operator

$$\hat{H}_{\rm ADM} = R_0^{-3}\frac{\partial^2}{\partial x^2} - \frac{4R_0^{-3}}{9x^2}\left[\frac{\partial^2}{\partial\beta_+^2} + \frac{\partial^2}{\partial\beta_-^2}\right] \qquad (12)$$

is self-adjoint with respect to the following inner product of wave functions of the Universe

$$\langle\Phi|\Psi\rangle = \iiint \Phi^*(x, \beta_+, \beta_-)\Psi(x, \beta_+, \beta_-)\,{\rm d}x\,{\rm d}\beta_+\,{\rm d}\beta_- \quad (13)$$

The Schrödinger equation to be solved for the wave function of the Bianchi I Universe is then

$$i\frac{\partial\Psi}{\partial t} = R_0^{-3}\left[\frac{\partial^2\Psi}{\partial x^2} - \frac{4}{9x^2}\left(\frac{\partial^2\Psi}{\partial\beta_+^2} + \frac{\partial^2\Psi}{\partial\beta_-^2}\right)\right] \qquad (14)$$

whose acceptable solutions for Ψ must be bounded in the complete domain of definition of the variable x, β_+ and β_-, that is

$$x \in [0, +\infty],\ \beta_+ \in [-\infty, +\infty] \text{ and } \beta_- \in [-\infty, +\infty].$$

The general solution Ψ of equation (14) can be written as a superimposition of particular solutions for the values E, p_+ and p_- of the separation constants

$$\Psi(x, \beta_+, \beta_-, t) = \alpha\iiint C(E, p_+, p_-)\Psi_{E,p_+,p_-}(x, \beta_+, \beta_-, t)\,{\rm d}E\,{\rm d}p_+\,{\rm d}p_- = \alpha\iiint C(E, p_+, p_-)\,{\rm e}^{-iEt}\cdot\exp[i(p_+\beta_+ + p_-\beta_-)]\cdot Y_{E,p_+,p_-}(x)\,{\rm d}E\,{\rm d}p_+\,{\rm d}p_- \qquad (15)$$

where $C(E, p_+, p_-)$ is the amplitude of the eigenstate of particular values E ($E < 0$; see equations (4b) and (10) see also Moncrief[30]), p_+ and p_- of the separation constants; α is an overall normalisation constant and $Y_{E,p_+,p_-}(x)$ is solution of

$$x^2\frac{{\rm d}^2Y}{{\rm d}x^2} + [\tfrac{4}{9}(p_+^2 + p_-^2) + R_0^3|E|x^2]Y = 0 \qquad (16)$$

This solution can be written as follows

$$Y_{E,p_+,p_-} = \bar{\alpha}x^{1/2}[AJ_{+(\frac{1}{4}-\frac{4}{9}(p_+^2+p_-^2))^{1/2}}(xC^{1/2}) + BJ_{-(\frac{1}{4}-\frac{4}{9}(p_+^2+p_-^2))^{1/2}}(xC^{1/2})] \qquad (17a)$$

With

$$C = |E|R_0^3 \qquad (17b)$$

Where J_ν is the Bessel function of order ν. A and B are constants determined by initial conditions and $\bar{\alpha}$ a constant of normalisation such that

$$\langle\Psi_{E,p_+,p_-}|\Psi_{E',p'_+,p'_-}\rangle = \delta(E-E')\delta(p_+-p'_+)\delta(p_--p'_-)$$

This solution is acceptable due to the asymptotic behaviour of $J_\nu(z)$ for $|z|\to\infty$. Moreover, by taking into account the behaviour of $J_\nu(z)$ for $z\to 0$, one deduces that

$$\Psi^*_{E,p_+,p_-}\Psi_{E,p_+,p_-} \xrightarrow[x\to 0]{} 0 \qquad (18)$$

We conclude that for a 'dust-filled' Bianchi I cosmological model, the classical singularity is avoided due to the presence of quantum gravitational effects in the sense that because $\Psi^*\Psi(x = 0) = 0$, it is impossible to find this Universe in the singular state.

For the isotropic version of the 'dust-filled' Bianchi I model, that is for the 'dust-filled' Einstein–de Sitter model ($\beta_+ = \beta_- = 0$), the wave function becomes zero at $x = 0$ only for a set of measure zero of models, which means that, in this case, the singularity will not be avoided.

The cause of possible singularity avoidance in the 'classical' quantum (or classical) regime[5–9], is usually ascribed to a violation of the energy condition of Hawking and Penrose's[1,2] theorems. We feel, however, that the non-singular character of the Bianchi I model studied here in the framework of quantum cosmology may be due to the fact that the quantum gravitational fluctuations do not allow the model to be sufficiently localised. Moreover, the singular Einstein–de Sitter models may be considered as very improbable (structurally unstable) models in the ensemble of all anisotropic Bianchi I Universes.

It would be interesting to extend the present work to the case of Bianchi-type models filled with a perfect fluid of equation of state: $p = (\gamma - 1)\rho$, which covers Zel'dovich's[30] stiff equation of state ($p = \rho$) as well as the hard equation ($p = \frac{1}{3}\rho$) characteristic of Collins and Perry's[31] 'quark soup'. This analysis would perhaps allow us to conclude as regards the truth of Wheeler's[32] conjecture "that every quantum solution for the problem of a closed universe within the framework of Einstein's field equations leads to a singularity". Work in this direction using Moncrief's[29] recent hamiltonian formalism for perfect fluids and Schutz's[17] formalism is in progress.

I thank Dr V. Moncrief for helpful comments and Dr P. Jasselette for interesting discussions.

Stability of quadruple junctions

THE analysis of triple junctions (points on the Earth where three lithospheric plates meet) has proved to be a powerful tool in deciphering the plate tectonic evolution of the Earth. In their classic paper on the evolution of triple junctions[1], McKenzie and Morgan dismissed the possibility of stable quadruple junctions existing more than instantaneously. We show here that quadruple junctions can be stable according to the vector velocity stability criteria of McKenzie and Morgan.

Consider the quadruple junction configuration of Fig. 1. Both spreading centres (A–B and C–D) extending into the junction

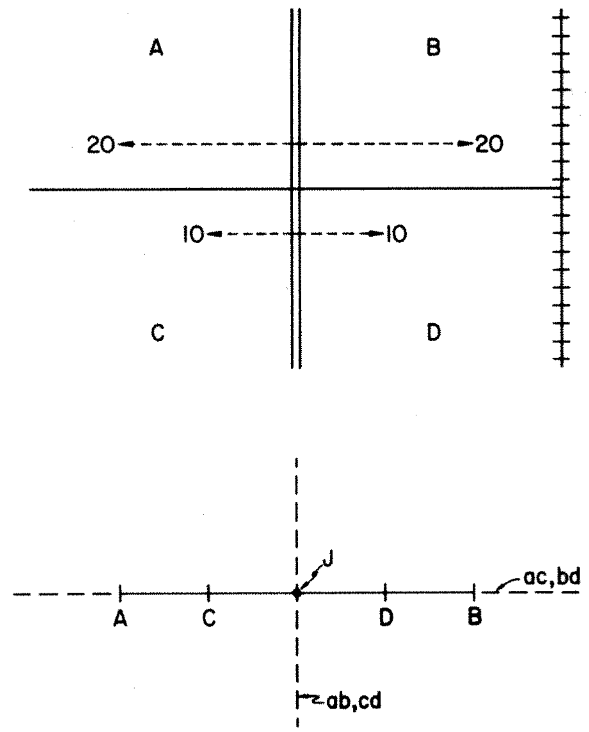

Fig. 1 Example of a stable quadruple junction and its representation in velocity space. Double lines are ridges, single lines are transform faults, hatchured line is trench. Arrows show relative plate motions. J represents quadruple junction.

spread symmetrically at the rates shown. Plate A therefore slips 10 mm yr^{-1} west relative to plate C and plate B slips 10 mm yr^{-1} east relative to plate D. This RFRF junction can clearly evolve continuously in this geometric configuration, which is confirmed by vector velocity analysis[1] (Fig. 1) or with scissors and paper. It is thus stable in the McKenzie–Morgan sense.

Many other stable quadruple junction configurations have been calculated by one of us (P.M.). Only the TFFF and FFFF junctions have no possible stable configuration. We note that stable quadruple and higher order *n*-tuple ridge junctions are possible if all *n* plate velocities fall along a circle in velocity space. All relative plate motions would be represented by chords of the circle, and the junction would have the vector velocity of the centre of the circle. Note that if this velocity criterion is met, the ridges can be at any orientations and the junction will be stable (the total angular spread of the ridges must be more than 180° if spreading is required to be non-oblique on all ridges; see ref. 3). If all four plate boundaries are orthogonal, five possible stable quadruple junctions may exist which do not require a specific ratio of plate velocities (RRRR, RFRF, RTRT, TTTF, and TTTT). In each of these cases, however, plate velocities are somewhat constrained by the geometric requirements; spreading is required to be symmetric and non-oblique, all transform faults are pure strike-slip, some subduction is required to be oblique and some non-oblique, and the subducted plate at each trench must be specified. These junctions are the only quadruple junctions which do not require both a specific geometry and specific plate velocities for stability. A possible situation in which a RRRR junction might be formed is during initial doming and rifting of a continent. If this happened, the subsequent establishment of normal seafloor spreading could result in a pair of failed rifts (aulocogenes) extending away from the quadruple junction.

There is a near quadruple junction today where the Pacific, Philippine, China and Australian plates nearly come together at the southern tip of the Philippine plate. There is also a near-juncture of the Pacific, Cocos, Rivera, and North America plates near the mouth of the Gulf of California. This could be a stable quadruple junction fixed with respect to the Rivera plate if the Pacific–Cocos spreading centre had the same vector velocity as the Rivera plate.

We agree with McKenzie and Morgan that quadruple junctions are unlikely to be of much importance in the Earth's evolutionary history, but a necessary step in identifying possible quadruple junctions is the recognition that they may exist.

Charge transfer by surface states in the photoelectrolysis of water using a semiconductor electrode

THE photoelectrolysis of water using n-type semiconductors such as TiO$_2$, (refs 1–4) SrTiO$_3$, (refs 5–7) and so on is of current interest and importance for the utilisation of solar energy to produce hydrogen gas for fuel. In steady state conditions under illumination and in the absence of H$_2$ and O$_2$ in the electrolyte, the rate of H$_2$ evolution on a cathode is proportional to that of O$_2$ evolution on a semiconductor anode. The O$_2$ evolution process is considered to proceed by electron tunnelling from electrolyte levels to holes in the semiconductor through the Helmholtz layer, which must take place between states of equal energy. If only isoenergetic electron transfer between holes and occupied electrolyte states overlapping in energy the valence band occurs, the hole currents for O$_2$ evolution at n-TiO$_2$ would be expected to be very low, because the equilibrium redox level of the H$_2$O/O$_2$ couple is considerably above (at 1.8 eV for $pH = 4.7$ (ref. 2)) the top of the valence band. Experimentally, however, the current of holes at the TiO$_2$-electrolyte interface is found to be quite high and the efficiency in charge transfer of holes at the interface is almost 100%[8]. To account for such a high efficiency, a contribution from some surface states has been proposed[8,9]. A possible importance of surface states in electrochemistry at TiO$_2$ electrodes has been described by Frank and Bard[10]. Also, a recent electroluminescence measurement made for n-TiO$_2$ indicates that occupied surface states exist near the midgap at the TiO$_2$–electrolyte interface[11]. At present, however, it is not understood which kind or character of surface states can improve the charge transfer efficiency for holes at the interface. We present here a theoretical treatment of electron tunnelling between the semiconductor and electrolyte by surface states. We apply a theory of surface states (more exactly interface states) in tunnel MOS (metal-oxide–semiconductor) devices of Freeman and Dahlke[12] to the semiconductor–electrolyte interface. A quite high efficiency for holes at the interface can be obtained when the electron population of the surface states is controlled by the electrolyte and the surface states are almost completely occupied.

The energy band diagram of an n-type semiconductor in an electrolyte under hole injection (by illumination) is shown in Fig. 1. For simplicity we assume that the surface states can be described by a single energy level E_t with a surface density of N_t. The charging of the surface states can take place by interaction with electrons in the conduction and valence bands of the semiconductor and by tunnelling of electrons between the surface states and electrolyte. In the steady state condition, the total

0028-0836/79/0277—0202$01.00

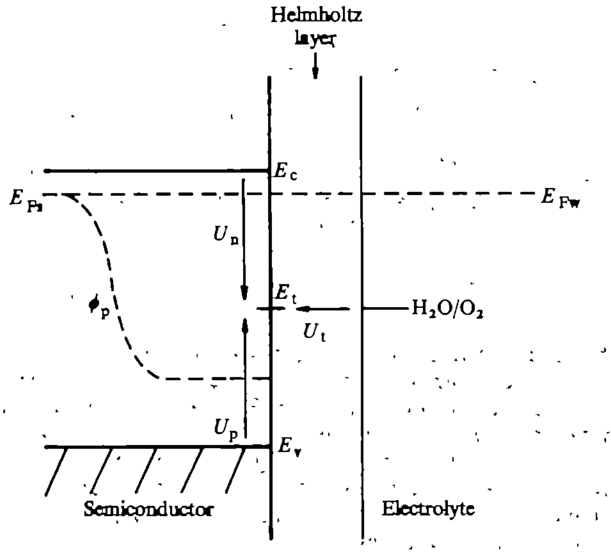

Fig. 1 Energy-level diagram for an n-type semiconductor–electrolyte interface with surface states at energy E_t and H_2O/O_2 redox level. The level E_{Fw} in the electrolyte and the Fermi level for electrons E_{Fs} in the semiconductor are aligned. The change in the quasi-Fermi level for holes ϕ_p is greatly exaggerated for clarity and indicates an increase in concentration of holes in the surface region of the semiconductor under illumination.

flux of electrons into the surface states must be equal zero. Then, the electron tunnel flux from the electrolyte into the surface states through the Helmholtz layer, which is proportional to the O_2 evolution rate, can be described as[12]

$$U_t = N_t(f_w - f_0)/(\tau_t + \tau_0) \tag{1}$$

Here, τ_t is a tunnelling time constant, f_w is an occupancy of the electrolyte states, and τ_0 and f_0 are constants characteristic of the surface recombination without tunnelling and are given by, respectively,

$$\tau_0 = [C_p(p_s + p_1) + C_n(n_s + n_1)]^{-1} \tag{2}$$

and

$$f_0 = \tau_0(C_p p_1 + C_n n_s) \tag{3}$$

where C_n and C_p are electron and hole capture coefficients, n_s and p_s are electron and hole concentrations at the surface of the semiconductor, and n_1 and p_1 are concentrations of electrons and holes to be expected when the Fermi level is at the surface state level.

If we assume that $\tau_t \ll \tau_0$ and $f_w = 1$, we have from equation (1)

$$U_t = N_t(C_p p_s + C_n n_1) \tag{4}$$

These conditions result in the situation that the electron population of the surface states is controlled by the electrolyte and the surface states are almost completely occupied. Furthermore, the condition of $\tau_t \ll \tau_0$ implies that the capture coefficients C_n and C_p in equation (2) should be sufficiently small.

Equation (4) indicates that U_t is determined by the hole capture from the valence band to the surface states and the electron emission from the surface states to the conduction band. In other words, an electron which tunnels from the electrolyte into the surface states either recombines with a hole in the valence band or enters the conduction band. The latter may be neglected compared with the former under illumination by which the surface concentration of holes p_s is increased, as n_1 is small when the surface state level is located near the midgap. Thus, U_t, that is the O_2 evolution rate is determined by the rate at which the almost completely occupied surface states capture holes at the semiconductor surface and is proportional to the surface concentration of holes, being in turn proportional to the light intensity of illumination, as observed experimentally. Because the hole emission from the surface states to the valence band is neglected in these conditions, it follows that all the holes reaching the semiconductor surface can be captured by the surface states and recombine with electrons in the electrolyte with the transfer probability of one. This can result in quite high efficiencies in charge transfer of holes at the interface.

Both the conditions of $\tau_t \ll \tau_0$ and $f_w = 1$ can be satisfied by the n-TiO_2 electrode, as the Helmholtz layer existing on the electrode is thin enough (of the order of 1 Å) to satisfy $\tau_t \ll \tau_0$ although the capture coefficients in TiO_2 are unknown, and $E_t = 1.5 \sim 1.24$ eV (ref. 11) and $E_{Fw} = 2.3$ eV (ref. 2) above the top of the valence band gives $f_w = 1$, where E_{Fw} corresponds to the Fermi level in the electrolyte. This explains the quite high transfer efficiencies observed at the TiO_2–electrolyte interface. But, it is not clear whether the surface states closely related to charge transfer at the TiO_2–electrolyte interface are pre-existing ones associated with surface $Ti^{3+}(3d^1)$ species[13,14] or some localised states occurring as a result of chemical bonding between the electrode and electrolyte. To clarify this point, further experiments for charge transfer at the interface using TiO_2 or $SrTiO_3$ electrodes with and without pre-existing surface states would be desired.

Finally, if we assume $\tau_t \gg \tau_0$, the U_t value is only a small fraction τ_0/τ_t of that for the case of $\tau_t \ll \tau_0$ and very low efficiencies in charge transfer are predicted.

High frequency radar observations of horizontal plasma waves in the equatorial ionosphere

THE anomaly observed on the magnetic field records in equatorial zones is due to a strong ionospheric current flowing around 105 km, called the equatorial electrojet. We have used coherent radar returns from electron density irregularities embedded in this current to measure electric fields in this region and to study plasma instabilities at the origin of these irregularities. We report here that strong anomalous reversals of the equatorial electrojet are sometimes observed and quasi-horizontal plasma waves have been detected for the first time during such an event.

Plasma instabilities have been previously investigated in the equatorial electrojet using VHF and HF radars[1,2] and *in situ* measurements during rocket launches[3] While a good height resolution is obtained with rocket measurements, wave spectrum information has only been obtained through radar measurements. However, due to Earth curvature, the classical VHF radar, as used at 50 MHz in South America, is not adapted to detect plasma waves moving at grazing angles below about

10° at the electrojet altitude of 105 km (ref. 4). It is only when HF radars are used that the refraction in the E region of the lower frequency radio rays is sufficient for a possible detection of these horizontal plasma waves, the properties of which are known from the theory to be specially interesting[4].

Such an HF experiment has been developed near the magnetic equator at Addis Ababa (Ethiopia) since 1976 using a phase coherent HF radar operating at 7, 14, 21 and 29 MHz. At the lower frequencies, radio rays are usually totally reflected by the E layer during daytime but, while classical oblique radar echoes have been observed almost every day[2] and identified as the so-called 'type 1' or 'type 2' echoes discovered previously at VHF[1], nothing typical was ever detected related to horizontal radio rays. It is only during a very strong counter-electrojet event described elsewhere[5] that very anomalous echoes were found to be associated with the horizontal radio rays.

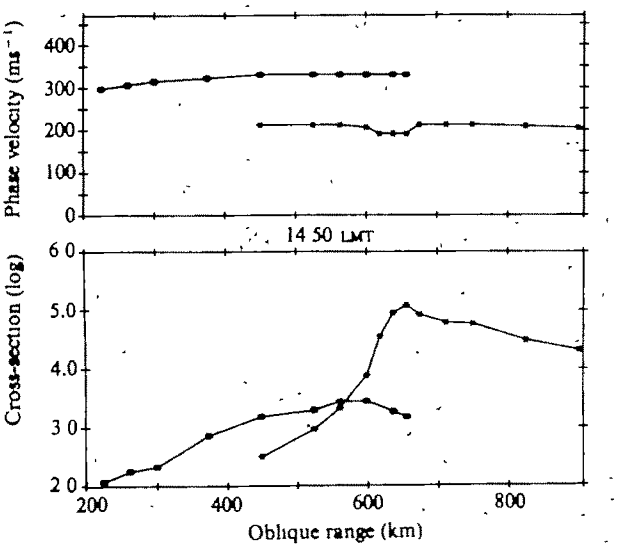
On 21 January 1977 coherent HF radar measurements were performed for the first time during a strong counter-electrojet. During such an event, the upward electron density gradient of the E layer is no longer destabilising due to the reversal of the electric field[6] and the cross-field instability cannot grow; however, the electron velocity is large enough (larger than the ion acoustic velocity in the medium) for the two stream instability to grow. It was then the first opportunity to investigate this instability without a background of turbulence due to the cross-field instability.

The spectral analysis of the radar echoes obtained at 14 MHz was performed at different time delays after the transmitted pulse corresponding to a variation of the zenith angle and a selection of different instability wave vectors (Fig. 1). The most striking and unexpected result is the discontinuity in both phase velocity and cross-section as a function of range and the simultaneous occurrence of two echoes for some ranges.

At the shortest ranges (or more oblique wave vectors) the phase velocity is larger and the cross-section much smaller than at the largest ranges (or more horizontal wave vectors). The shortest range echoes are similar to the usual 'type 1' echoes and are labelled accordingly (Fig. 1).

These experimental results can be considered in the light of a ray tracing of radio wave propagation for the conditions prevailing in the E layer at the time of the observations ($f_{oE} = 3$ MHz, $H_{max} = 105$ km). It is found (Fig. 2) that radio rays can be horizontal further than about 600 km, while strong refraction is still observed between 450 and 600 km. The strong amplitude and low phase velocity echoes labelled 'type H' on Fig. 1 can then be associated with horizontal and quasi-horizontal plasma wave vectors with a maximum cross-section for the horizontal waves. The association of the 'type H' echoes with the horizontal waves is confirmed by the time variation of the location of the amplitude maximum: the range of this maximum increases with time as given by the ray tracing when the E layer critical frequency decreases (that is, totally refracted echoes are observed at greater ranges).

Fig. 1 Phase velocity and scattering cross-section variation for type 1(O) and type H (•) echoes with the oblique range (in km) in the eastward direction at 14.50 LT on 21 January 1977 at Addis Ababa.



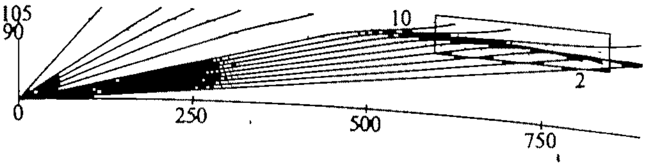


Fig. 2 Radio ray tracing at 14 MHz using a parabolic E layer ($f_{oE} = 3$ MHz, $h_{max} = 105$ km, $H = 7.5$ km) showing the horizontal radio rays further than 500 km.

The 'type H' echoes observed during the 21 January counter-electrojet event can then be associated with horizontal or quasi-horizontal plasma waves. The fact that such a phenomenon is not observed during normal electrojet conditions could be due to the turbulent state of the current flow when long wavelength cross-field instabilities grow in the normal daytime electrojet. When the electric field and the current are reversed during the counter-electrojet with no modification of the upward electron density gradient, the cross-field instability cannot grow and the turbulent mixing does not appear. The current flow is then always in a laminar state and the first waves appearing (the horizontal ones) will not have their growth rate modified by the turbulence as during normal electrojet conditions.

The characteristics of the 'type H' echoes cannot be definitely associated with either two stream (type 1) or cross-field (type 2) instabilities. On the one hand, the very narrow width of their spectrum, the strong amplitude and the lack of correlation between the phase velocity and the magnetic field variation are typical of type 1 spectra; on the other hand, the relatively low value of the phase velocity and the presence at the bottom of the layer are typical of type 2 echoes.

Among the two striking characteristics of type H echoes, the very strong amplitude is certainly associated with the fact that in a laminar electrojet the horizontal waves have the largest growth rate, but the other characteristic, the low value of the phase velocity, is still very puzzling and may be related either to some saturation effect similar to the quasi-linear reduction of the electric field[4] or to some secondary phenomena in the electrojet known to modify the phase velocity of the instabilities such as the presence of a strong neutral wind gradient with altitude or longitude or the occurrence of an anomalous gradient related to a thin blanketing sporadic E[7].

Gradual increase of oceanic CO_2

SINCE 1850, human activities, mainly the burning of fossil fuels and the clearing of forests, have increased the amount of CO_2 in the atmosphere by ~50 p.p.m.[1-5]. Although it is generally believed that the oceanic CO_2 has increased correspondingly[6-11], only very limited data[12-14] have shown the increase quantitatively. We present here a computational calculation of the variation of the preformed total CO_2 (ΣCO_2^0) for a water mass, the original amount of total CO_2 (ΣCO_2) at the time of its last contact with the atmosphere. The result for the Atlantic Ocean reveals that the older water masses have invariably smaller ΣCO_2^0 as compared to the more recently formed waters.

Assuming a parcel of seawater in contact with the air remains at a constant degree of equilibrium[15] with the atmospheric CO_2, the amount of ΣCO_2 in this water is defined as ΣCO_2^0, which depends on the partial CO_2 pressure in the air (p_{CO_2}) as well as the salinity and the temperature of the seawater. Once the water sinks, the *in situ* decomposition of particulate $CaCO_3$ and organic carbon adds dissolved CO_2 to the parcel[16,17]. Consequently, the measured ΣCO_2 becomes larger than ΣCO_2^0. The values of ΣCO_2^0 can only be calculated from the measured ΣCO_2 values by correcting for the influences of $CaCO_3$ and organic carbon, which in turn can be calculated using the titration alkalinity (TA) and the apparent oxygen utilisation (AOU) data. (The combined effect of decomposing x moles of $CaCO_3$ and y moles of organic matter in 1 kg of seawater on ΣCO_2^0, TA^0 and AOU can be represented as[16,17]:

$$\Sigma CO_2 - \Sigma CO_2^0 = x + 106y$$

$$TA - TA^0 = 2x - 17y$$

$$AOU = 138y$$

Eliminating x and y from the above equations yields equation (1). Note that the constant associated with AOU is 0.83 instead of the often misused 0.768.)

$$\Sigma CO_2^0 = \Sigma CO_2\ (\text{measured}) - 0.5[TA(\text{measured}) - TA^0] - 0.83\ AOU \qquad (1)$$

where TA^0 is the preformed TA value. The values for TA^0 probably do not vary with the atmospheric CO_2 variation but depend only on the salinity and temperature. Therefore, we have assumed that the present day surface TA values represent the values for TA^0 during the past 130 yr.

The Geosecs (Geochemical Ocean Section Study) Atlantic surface TA data have been fitted to a function of potential temperature (θ)[18].

We have calculated TA^0 (and other chemical properties) on the constant salinity (35‰) basis. The values of chemical properties, for example TA^0, are normalised to 35‰ salinity (S) using:

$$TA^0 = \frac{TA^0(\text{measured}) \times S(\text{‰, measured})}{35.000}$$

$$\begin{aligned} TA^0(\mu\text{Equiv. kg}^{-1}) &= 2{,}368 - 4.72\theta, & \theta < 17\,^\circ C \\ &= 2{,}287, & \theta > 17\,^\circ C \end{aligned} \qquad (2)$$

Combining equations (1) and (2) gives:

$$\begin{aligned} \Sigma CO_2^0(\mu\text{mol kg}^{-1}) &= \Sigma CO_2(\text{measured}) - 0.5TA(\text{measured}) \\ &\quad - 0.83\ AOU + 1{,}184 - 2.36\theta, \quad \theta < 17\,^\circ C \qquad (3) \\ &= \Sigma CO_2(\text{measured}) - 0.5TA(\text{measured}) \\ &\quad - 0.83\ AOU + 1{,}143.5, \quad \theta > 17\,^\circ C \end{aligned}$$

The values for ΣCO_2^0 for the Atlantic waters formed in 1972 have been assumed to be equal to the surface ΣCO_2 values determined in that year (Geosecs). They are represented by

$$\Sigma CO_2^0(\mu\text{mol kg}^{-1}, 1972) = 2{,}195 - 9.5\theta \qquad (4)$$

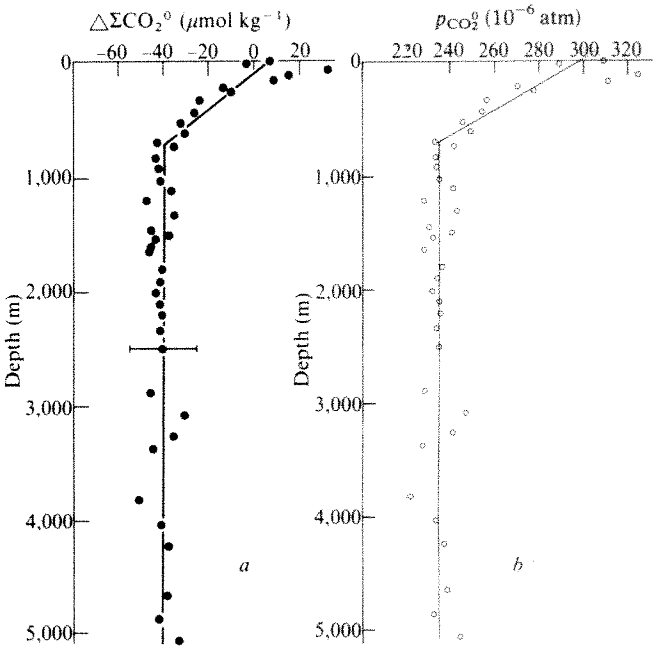

Fig. 1 Variations of $\Delta\Sigma CO_2^0$ (*a*) and $p_{CO_2^0}$ (*b*) with depth at 59°56.5′ S, 45°2.0′ W.

The difference in ΣCO_2^0 ($\Delta\Sigma CO_2^0$) between the older water masses calculated from equation (3) and the present day (that is 1972) values calculated from equation (4) is probably caused by changes in the atmospheric CO_2 concentrations. The uncertainty in $\Delta\Sigma CO_2^0$ is estimated to be ±15 μmol kg^{-1} due to the uncertainties in the measured chemical properties, namely ΣCO_2, TA and AOU.

The vertical variation of $\Delta\Sigma CO_2^0$ was calculated from a station in the Southern Ocean (Geosecs station 79; 59°56.5′ S, 45°2.0′ W). The values for $\Delta\Sigma CO_2^0$ decrease from approximately zero to nearly -40 ± 15 μmol kg^{-1} from the surface to 700 m, but remain constant from 700 m to 4,860 m (Fig. 1*a*). The decrease of roughly 40 ± 15 μmol kg^{-1} in $\Delta\Sigma CO_2^0$ with depth for the relatively young shallow waters reflects the decrease of atmospheric CO_2 with age. The deeper layer does not show depth-dependent variations in $\Delta\Sigma CO_2^0$, presumably because it was formed before the atmospheric CO_2 started to increase. The vertical profile for $p_{CO_2^0}$ (Fig. 1*b*) looks similar to the profile for $\Delta\Sigma CO_2^0$ and shows a decrease of 65 ± 30 p.p.m. from the surface to 700 m. Very little tritium, but large negative values for $\Delta^{14}C$ were found[19,20] below 600 m for waters south of 55° S, which confirms our conclusion. The variation in $p_{CO_2^0}$ is larger than the value generally accepted[1-5] or the value (50 p.p.m.) obtained by Brewer[14] using a similar approach.

Similar horizontal propagations of $\Delta\Sigma CO_2^0$ with latitude have been traced along the minimum salinity (Fig. 2*a*) and the minimum potential temperature (Fig. 2*b*) layers in the Atlantic Ocean. Figure 2*a* shows that the values for $\Delta\Sigma CO_2^0$ generally decrease from 45° to 20° S in the minimum salinity layer (~800 m deep). The break near 38° S is probably due to the change in flow patterns[21,22], as northwards flowing minimum salinity water turns eastwards at about 40° S and returns around the anticyclonic gyre. The water north of 38° S is significantly older than the water south of 38° S. There is probably another break at 22° S. The values of $\Delta\Sigma CO_2^0$ for water between 22° S and 25° N remain relatively constant at -40 ± 15 μmol kg^{-1}, indicating that there was no significant CO_2 variation in the atmosphere when this parcel of water was formed. The values

0028–0836/79/0277—0205$01.00

for $\Delta\Sigma CO_2^0$ increase with latitude north of 25° N due to the influence of the freshly formed North Atlantic Deep Water[23]. There are no significant differences between the waters in the western and eastern Atlantic Ocean.

The tritium data support our findings. The average tritium value is 0.47 tritium unit (TU) at the depths of interest south of 38° S. This value is higher than the average value of 0.15 found between 38° and 22° S, which in turn, is higher than the average value of 0.06 TU for stations between 22° S and 25° N. Tritium concentrations are high for stations north of 25° N.

The values for $\Delta\Sigma CO_2^0$ in the minimum potential temperature layer (roughly 4,500 m deep) are shown in Fig. 2*b*. Waters in the eastern basin all have $\Delta\Sigma CO_2^0$ values of approximately -40 ± 15 μmol kg^{-1}, indicating that these waters formed before the industrialisation. Waters in the western basin are apparently younger. The value of $\Delta\Sigma CO_2^0$ is $\sim -20 \pm 15$ μmol kg^{-1} near 50° S in the western basin which suggests that the water here has been influenced by the atmospheric CO_2 increase. In the south, values for $\Delta\Sigma CO_2^0$ show a northwards decrease in the western basin. The values decrease to -40 ± 15 μmol kg^{-1} and remain constant from 38° S to 10° N, then start to increase north of 10° N, presumably due to the influence of the rapidly sinking North Atlantic Deep Water. The value reaches nearly zero at 47°33′ N at a depth of 4,546 m which indicates that the water here is probably not much more than a few years old. The distributions of $p_{CO_2^0}$ (not shown) look similar to that of $\Delta\Sigma CO_2^0$.

The computational scheme given above represents only first approximations of the very complicated systems in the oceans. The Redfield–Kethchum–Richards model[24] has been assumed to be valid everywhere in the oceans[25], and the possible effect of sulphur on TA[16,17] has not been considered. Waters with the same θ have been assumed to have the same TA^0 and ΣCO_2^0 and the complicated effects of mixing and the slow vertical diffusive migration of CO_2 from the surface water to deep water regime (T. Takahashi, personal communication) have been neglected. Nevertheless, the method is simple and the results reveal details that have not been shown before. [The work of Brewer was brought to our attention during the preparation of this letter. Although his computational scheme is different from ours, the concepts fall on the same line. His results (his Fig. 2) are similar to part of our Fig. 2*a*.] Quantitatively, the results show that the oceanic ΣCO_2^0 has increased by as much as 40 ± 15 μmol kg^{-1} (or 65 ± 30 p.p.m. in $p_{CO_2^0}$) responding to the atmospheric CO_2 increase. Qualitatively, the results have indicated how far and how deep the human induced CO_2 has penetrated into the Atlantic Ocean. We hope this method can help us to understand better the global carbon cycles.

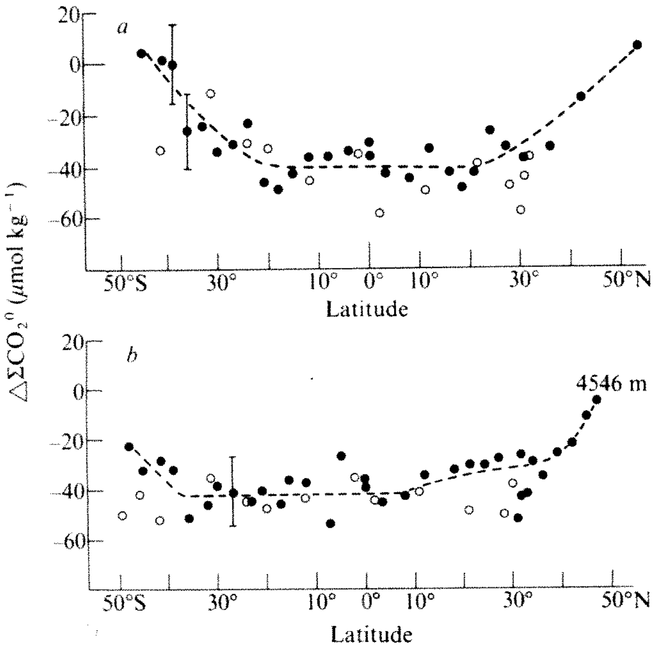

Fig. 2 Variation of $\Delta\Sigma CO_2^0$ with latitude along the minimum salinity (*a*) and minimum potential temperature (*b*) layers in the Atlantic Ocean. ●, Samples taken from the western basin; ○, samples from the eastern basin. The broken lines are drawn through the data in the western basin only.

Access to the Geosecs Atlantic data for alkalinity, ΣCO_2 and oxygen is acknowledged. We thank G. Ostlund, R. Fine, P. Niiler, L. Gordon and K. Johnson for assistance; C. Keeling, P. Brewer, T. Takahashi, R. Pytkowicz and E. Suess for helpful comments. Particulate uranium, plutonium and polonium in the biogeochemistries of the coastal zone

ALTHOUGH increasing attention has been paid to the role of inorganic solid phases in the chemistry of seawater, little quantitative data has been available to assess their involvement with living systems. We report here recent observations on the uptake of uranium, plutonium and polonium in coastal waters by organisms and submerged surfaces as traced by their isotopes. We show that the body burdens of these radioelements in some marine organisms are governed measurably by the uptake of their particulate forms. Furthermore, these elements are associated with different particulate phases as deduced from the rates at which they deposit on submerged surfaces.

The dissolved uranium content of marine waters seems to be related to the salinity[1]. For a salinity of 35‰, the uranium

0028-0836/79/0277—0206$01.00

concentration is 3·35±0·02 μg l^{-1},(2.48 d.p.m. l^{-1}). Moreover, the ^{234}U/^{238}U activity ratio is reported as constant at 1.14±0.02 (ref. 2). The disequilibrium of the uranium isotopes in seawater is a consequence of the daughter ^{234}U entering a more readily dissolvable state than its parent, ^{238}U, following its production in crustal rocks. There are several explanations for this phenomenon[3]. However, the important observation is that the ^{234}U/^{238}U activity ratio in river water is usually greater than unity, while in the residual solids it is usually of the order of or less than unity. Thus, any continental solid phases that are mobilised to the ocean through the rivers, winds or glaciers may be identified by a ^{234}U/^{238}U ratio, whose value is <1. The distribution of plutonium and polonium between soluble and particulate phases in California coastal waters is unknown.

We began exposing solid surfaces (for example, glass beads) to seawater in 1976 to ascertain whether plutonium, which seemed to accumulate on the giant kelps in relation to surface area[4,5], would be collected by 'non-living' material. The solids were immersed in seawaters off the Scripps Institution of Oceanography Pier in La Jolla for periods of up to a month, and assayed for plutonium, polonium, and uranium[2,4]. Independent of the type of material, glass beads, filter paper, alumina balls or PVC, there is a direct relationship between exposure periods and the amounts of uranium, plutonium and polonium picked up from seawater per unit surface area (Fig. 1). Moreover, the uranium ratio of the sorbed phases varies between 0.91 and 1.07, averaging 0.98±0.03, with probable errors (counting errors) of 0.03 or less.

In the process of attempting to identify the possible organometallic complex of uranium, a batch of glass beads was leached with a mixture of chloroform and methanol (2:1). Little of the uranium, plutonium and polonium dissolved in solvent mixture and little was retained on the beads. Instead, these radioactive elements were found in the small amount of particulate material that was released from the beads by the solvent. These elements were probably on particles that were fixed to the beads by some type of natural organic adhesive. Thus, submerged bodies, including living algae, may, by an organic coating on their surfaces, collect some fraction of the particles, and the associated inorganic elements, that impact their surfaces in proportion to exposure time and surface area.

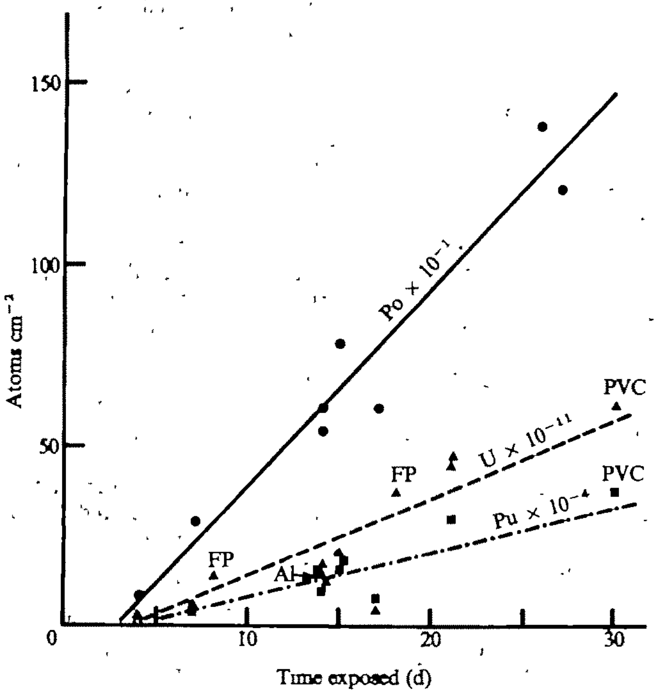

Fig. 1 Accumulations of uranium, plutonium and polonium in atoms cm^{-2} are plotted against the time exposed to seawater off the pier at Scripps Institution of Oceanography, except the 17-d exposure which is on a Navy platform one mile off shore. All points are for the exposure of glass beads except FP, Whatman 40 filter paper; Al, alumina balls; and PVC, polyvinyl chloride sheet. The accumulation rates are: U = 2.3×10^{11} atoms cm^{-2} d^{-1}; Pu = 1.2×10^{4} atoms cm^{-2} d^{-1}; and Po = 54 atoms cm^{-2} d^{-1}.

Table 1 ^{234}U/^{238}U activity ratio in particulates recovered from seawaters and in seawaters, from Southern California

Particulates collected					
By filtration (1 μm)	Date	^{234}U/^{238}U	^{238}U	$^{239+240}$Pu (d p m l^{-1})	^{210}Po
7,200 l	12/21/77	1 00±0.01	0.0022	0.000024	0.011
22,000 l	1/06/78	0 97±0 01	0 0023	0 000017	0 011
Collected by sedimentation and subsequently resuspended with overnight settling	11/10/77	1 00±0.02			
Collected by one month exposure of acrilan fibres	10/20/77	1.02±0.01			
Seawater					
Volume (l)					
unfiltered					
20	6/02/77	1.14±0 01			
20	7/22/77	1.15±0.01			
Dialysed					
20	9/01/77	1 16±0 01			
8	12/08/77	1.15±0.01			
8	12/19/77	1 15±0 01			

It is evident that a portion of uranium, plutonium and polonium in seawater is in particulate form. Of greater interest, however, is the difference in uptake slopes of all three elements on the solid surfaces (Fig. 1). This difference suggests that the elements, although in particulate form, may not be associated with the same solid phases.

Large volumes of seawater were pumped through 1 μm (nominal pore size) glass filters and the particulate material retained by the filters was found to contain concentrations of these elements in ratios roughly equal to those of the glass beads. The U/Po, U/Pu and Pu/Po ratios on an atom basis for the glass beads and seawater particulates were: 4.2×10^{9} and 2.4×10^{9}, 1.9×10^{7} and 2.1×10^{7}, 220 and 115 respectively. Moreover, the ^{234}U/^{238}U activity ratio of the particulates was unity (Table 1). Uranium isotopes were also determined on material that adhered to acrilan fibres exposed for one month in the kelp beds near Scripps and on sediment that collected in an 80 l barrel into which seawater flowed for a period of two months (Table 1). The barrel matter was resuspended in seawater and the fraction that did not settle overnight (<1–2 μm size fraction) was captured by centrifugation at 12,000g. The ^{234}U/^{238}U ratio of the particulates collected by these two methods was also essentially one (Table 1). In contrast, the total uranium in seawaters from the area has values of the ratio near 1.15 (Table 1). Volumes of seawater dialysed through membranes with molecular weight cut offs of 13,000 and 2,000 gave ^{234}U/^{238}U ratios of (1.15–1.16)±0.01 in the dialysate.

Thus, coastal seawaters near San Diego, California, possess a ^{234}U/^{238}U activity ratio of 1.15±0.01, while the particulate phases contained therein and originating on the continents have values around unity. Even though the particulate materials comprise <1% of the uranium content in the dissolved state, could their impact on the biosphere be quantified? To assess this possibility, the uranium in the soft tissues of filter feeding organisms was assayed for their uranium isotopic composition (Table 2). Brown algae were also analysed.

For most of the biological samples, the ^{234}U/^{238}U activity ratio is less than that of dissolved uranium (1.15). Note that the soluble uranium activities contributed by the water that constitutes the difference between the wet and dry weights were not subtracted and would only tend to enhance the role of particulate uranium if a correction were made. The largest deviation from the seawater is in scallops with a value of 0.96±0.01. On the basis of the uranium isotopic ratio, assuming uranium of dissolved origin has a ratio of 1.15 and particulate uranium a ratio of 0.98, all the uranium found in the scallops was due to the uptake of particulate uranium. Likewise, the observation that the mussels have an average value for the ratio of 1.13 indicates that about 11% of their uranium was taken up as solid phases. The mussels have remarkably high values of uranium in their byssal threads, over 10 times more than in their bodies on the average, and this uranium seems to have arisen primarily from the dissolved state in seawater.

The tunicates, on the other hand, have values of the $^{234}U/^{238}U$ ratio markedly lower than those of the mussels. These filter feeders have high hydrogen ion concentrations in their gut regions which could leach uranium from the particulate phases. Both bodies and gut were analysed in three samples. In every case the gut materials had lower values of the ratio but similar values of the uranium concentrations compared to the bodies. Clearly, the particulate phases in seawater contribute significantly to the uranium body burden of these organisms.

The $^{234}U/^{238}U$ activity ratio in the algae ranges from 1.09 to 1.16, indicating contributions from both dissolved and particulate uranium. The elk kelp blade (1.16) was thick relative to the macrocystis blades, and thus had less surface area per unit weight for particle deposition. The reverse is seen with the elk kelp scrapings, which maximise the area to weight and have the lowest ratio of the uranium isotopes (1.09)—indicating that 35% of the accumulated uranium was in the particulate form.

Polonium and plutonium are most probably taken up by the algae in a particulate state, by impact as opposed to active processes. The Pu/Po atom ratios on the glass beads and kelp are 220 and 280 respectively. The ratio for seawater particulates is 115, also roughly the same. Even more remarkable is that the rates of uptake of polonium and plutonium in atoms cm^{-2} d^{-1} by the glass beads and the kelp are essentially identical, Po = 54 and 52 (ref. 4) and Pu = 1.2×10^4 for both the beads and kelp[4].

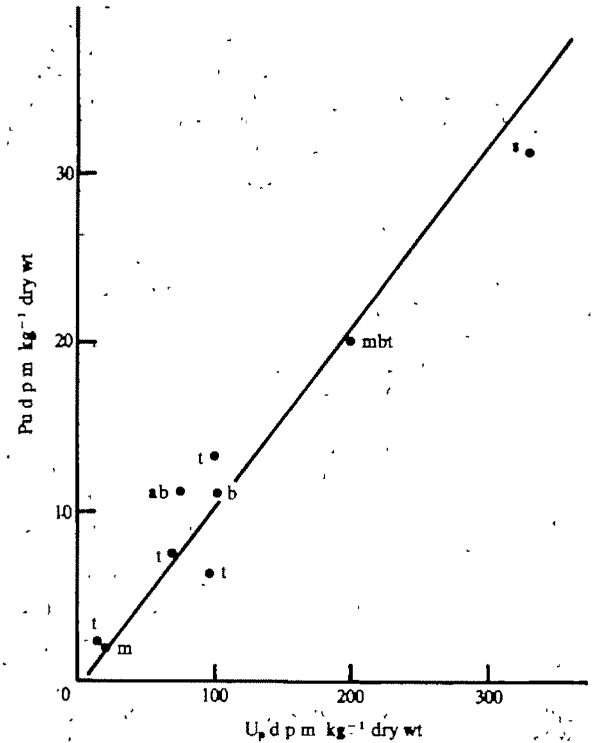

Fig. 2 The activity of plutonium and particulate uranium U_p are linearly proportional with a slope of 1/10. s, scallops; mbt, mussel byssal threads; t, tunicates; ab, abalones; b, barnacles; and m, mussels.

The plutonium concentrations in the other marine organisms are linearly proportional to the uranium of particulate origin (Fig. 2). Thus, the uptake of plutonium by these organisms may be related to the ingestion of this transuranic in a particulate form.

Clearly, uptake of particulates can significantly influence the uranium, polonium and plutonium content and the uranium isotopic ratio of coastal marine organisms. By simply measuring the uranium isotopic ratios, the extent to which particulate uranium is important can be quantitatively determined. Using the same approach, it may be possible to assess the role of particulate trace elements by comparing their specific activities, for example, ^{210}Pb/stable lead or $^{238}Pu/^{239+240}Pu$ on particulate phases in seawater and in the organisms.

These studies also point out that caution must be exercised in calculating a concentration factor for trace elements in organisms over the concentration of that element in seawater. For example, the scallops accumulate particulate uranium exclusively and, therefore, using the ^{238}U particulate concentration in seawater of 0.002 d.p.m. l^{-1} (Table 1), the concentration factor based on the dry weight of the organisms is 1.5×10^5. Had the total ^{238}U seawater concentration been used to calculate this factor, a value of roughly 150 would have been reported. Note that the build up on the beads after one month of exposure to seawater for uranium, plutonium and polonium is ~1×10^7, using the fact that 4.5 kg of beads collect nearly 1 g of dry particulates. On the other hand, the byssal threads of the mussels from Bodega Head, California, have a concentration factor for soluble uranium of 3.3×10^3 and one for insoluble uranium of 7.4×10^5.

^{10}Be in marine sediments, Earth's environment and cosmic rays

COSMIC RAYS create the long-lived radioactive nuclide ^{10}Be (half life: 1.5 M yr) continuously in the upper atmosphere as a result of nuclear disintegrations. It enters the oceans through various paths and finally deposits in deep-sea sediment in a time which is short compared to its half life. This isotope has been used to establish the chronology of geophysical events up to the Pliocene[1–7] or to suggest cosmic-ray intensity variations in the past[8,9]. This report shows that the ^{10}Be stratigraphy in marine sediments can be used as a time marker for geophysical events in the past, but not for delineating any time variations in cosmic-ray intensity unless one can learn how to delineate geophysical effects. Also the cosmic-ray consistency would be estimated from the limits of ^{10}Be variation implied by this data set.

A sediment core (KH68-4-18), 968 cm in length, was collected from a 5,390 m deep-ocean basin at 01° 59′ N, 170° 01′ W, central equatorial Pacific. Beryllium was separated from the sediment samples using an improved chemical method[10], and the β-ray activity of ^{10}Be was counted with two sets of low-level needle counters[11] and a low-level silicon detector; background count rates and counting efficiencies of these were $0.0082 \pm 0.0005\ \mathrm{min}^{-1}$, $51 \pm 3\%$, $0.0072 \pm 0.0005\ \mathrm{min}^{-1}$, $51 \pm 3\%$, $0.0372 \pm 0.012\ \mathrm{min}^{-1}$, $35 \pm 2\%$ (90–555 keV), respectively.

The absolute age $T(x)$ at a depth x was evaluated[12] from a rate of ^{10}Be participation, P (atoms cm^{-2} s^{-1}), onto sediment surface and the specific activities of ^{10}Be, $N(x)$ (d.p.m. cm^{-3} or atoms cm^{-3}), in all successive layers along the core down to a depth, x.

$$N(x)=\frac{P}{S(x)}\exp\left[-\lambda T(x)\right]. \qquad dT(x)=\frac{dx}{S(x)}$$

or

$$T(x)=-\frac{1}{\lambda}\ln\left[1-\frac{\lambda}{P}\int_0^x N(x)\,dx\right]$$

Here, λ is a decay constant of ^{10}Be and P is assumed to be constant and equal to 2.15×10^{-2} ^{10}Be atoms cm^{-2} s^{-1}, during the time interval considered for this core, and the sedimentation rate at a layer, $S(x)$, is assumed to have varied with depth or time.

The specific activities of ^{10}Be and the ^{10}Be ages are listed in Table 1 together with magnetic ages[13], differential sedimentation rates and the content of Be and Mn. The uncertainty in the specific activities was estimated on the basis of the uncertainties (1σ) in chemical determination of beryllium (8%), counting efficiency (5%), absorption correction (5%) and counting statistics (7–17%).

The ^{10}Be ages agree well with the magnetic ages at six reversal horizons (Table 1). The magnetic reversal pattern of core KH68-4-18 is very clear and consistent with palaeontological analysis[13]. These agreements show that the assumption of constant ^{10}Be precipitation would be correct and the cosmic-ray production rates integrated over the time intervals ($2–7 \times 10^5$ yr) between each adjacent reversals have been constant ($< \pm 10\%$

* *In situ* density is defined as the ratio of the dry weight of sediment to the *in situ* volume occupied by the sediment.

† The depth is measured from the top of clay sediment filled in core pipe, whereas the depth presented in ref. 5 where the magnetic age has been determined is measured from the top of core pipe; the difference is 15 cm. The magnetic age tabulated here is normalised to the present depth.

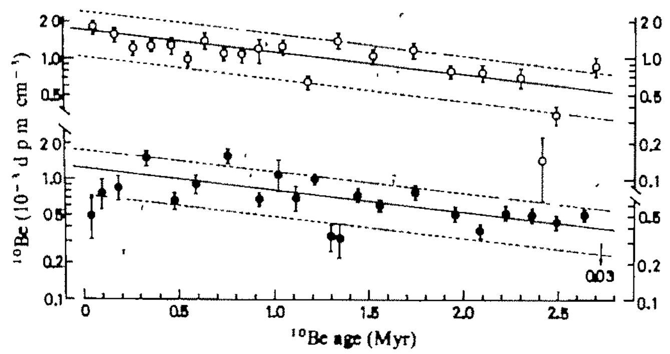

Fig. 1 Comparison of the ^{10}Be variations with time in two Pacific deep-sea sediment cores: ○, KH68-4-18; ●, KH68-4-25. Data for core KH68-4-25 taken from ref. 12. Mean decay lines are shown by solid lines, with ±40% limits of variation by dotted lines.

variation) up to 2.5 Myr BP. The differential sedimentation rates at different layers vary by a factor of 2 from ~2.5 mm kyr^{-1} to ~5 mm kyr^{-1} except for 15 mm kyr^{-1} at a layer 790–850 cm. The mean sedimentation rate is 3.5 mm kyr^{-1} consistent with the value of 3.4 mm kyr^{-1} (ref. 13) derived from magnetic stratigraphy.

The ^{10}Be activities in core KH68-4-18 (2° N, 170° W) and a previously investigated[12] core KH68-4-25 (20° S, 170° W) are plotted against the ^{10}Be ages in Fig. 1.

The ^{10}Be activities in the two cores do not parallel each other in the past. This fact rules out cosmic-ray intensity changes as the principal cause for the ^{10}Be variations. Another fact unfavourable to the simple cosmic-ray interpretation is that the rate of ^{10}Be precipitation at 2° N (2.15×10^{-2} atoms cm^{-2} s^{-1}) is twice as large as that at 20° S (1.14×10^{-2} atoms cm^{-2} s^{-1}, see ref. 12). If the ^{10}Be precipitation rate reflects the latitudinal variation of the overhead ^{10}Be fallout[14], the P values for the two cores would be reversed.

Non-parallelism of the ^{10}Be variations in the two cores is also unfavourable to a simple global climate change as a main cause for the ^{10}Be variations[15], although the glacial and interglacial effects in principle could influence the ^{10}Be content of ocean sediments in a relatively complex fashion.

One of the most significant differences between the two cores is the low ^{10}Be concentrations (Recent 0.27 Myr) at the top of core KH68-4-25, that do not occur for core KH68-4-18. Tanaka *et al.*[12,16] showed that the volcanism of Samoan island arc caused the decrease at the top of core KH68-4-25, on the bases of the abundance of volcanic glassy fragments and the variation of elemental abundances. In core KH68-4-18, there are no glassy fragments of volcanic origin and no correlation between the concentrations of ^{10}Be and elemental abundances; volcanism has little effect for this core. This equatorial core has plenty of fossils of faunal and floral species throughout (30–80% in volume under microscope), with exceptions at depth 415–465 cm (1.13–1.23 Myr) and 790–850 cm (2.39–2.43 Myr) where the fossil occurrences are sporadic (less than a few %) and the ^{10}Be concentrations are low (see Fig. 1). Biological productivity may cause changes in ^{10}Be concentrations.

Another set of analysis will be stated on the limits of ^{10}Be variation implied by this data set. The data show some scatter in the plot of log $N(x)$ versus time (Fig. 1), but the decay line (solid lines in Fig. 1) having the slope of a half life of 1.5 Myr which starts from the $N(0)$ value derived from the adopted P value and mean sedimentation rate seems to be representative for the data set. The limits of ^{10}Be variation from the mean line are ±40% for both cores, represented by dotted lines in Fig. 1. A few points beyond the limits can be explained by special effects such as the presence of volcanic fragments or the low biological productivity. The ^{10}Be variations are mainly affected by complex environmental factors, and the cosmic-ray intensity variations, if any, do not exceed at most ±40% for period of ~1×10^5 yr (sampling intervals) during the past 2.5 Myr.

The ^{10}Be variations with time and with oceanic location reflect complex changes in the Earth's environment such as volcanism, biological productivity, oceanic circulation, and climate. The cosmic-ray intensity variations, if any, do not exceed ±10% for periods of 2–~7×10^5 yr and ±40% for periods of ~1×10^5 yr during the past 2.5 Myr, and can not be delineated from this data set.

Human chimaera detectable only by investigation of her progeny

A CHIMAERA can be defined as an organism whose cells derive from two or more zygotes[1]. In man, two categories of spontaneous and permanent chimaeras are recognised: blood chimaeras which arise from the exchange of blood-forming cells between dizygotic twins, and dispermic chimaeras which are the result of the fusion of two zygotes and of their growth into one body (for review see ref. 2). Blood chimaeras are usually identified because of blood-grouping problems caused by the mixture of different erythrocyte populations, while dispermic chimaeras who often present sex abnormalities are mainly detected by cytogenetic studies, although they also carry a mixture of different blood cell populations. In contrast to these typical cases, we now report a unique human chimaera who shows no mixture of blood cells as far as the genetic markers investigated are concerned, and who is only detectable by the investigation of the blood of her progeny (family Eiw., Fig. 1).

This chimaera was brought to our attention because of an apparent mother–child exclusion in the ABO system: mother II.2: A_2B, child III.4: 0. Blood samples of the mother II.2, her husband II.1, her children III.1–III.4 and her parents I.1 and I.2 were typed for the following markers: ABO, rhesus, MNSs, P, Kell, Duffy, Kidd, Lutheran, Lewis, ABH- and Lewis-secretion, Xg, acid phosphatase acP-1, phosphoglucomutase PGM-1 (including the subtypes, PGM-1*, defined by isoelectric focusing on polyacrylamide gel[3]), adenylate kinase AK-1, adenosine desaminase ADA, glutamate pyruvate transaminase GPT, glyoxalase GLO-1, esterase D EsD, gammaglobulin groups Gm

Table 1 Genetic marker systems showing mother–child exclusions (family Eiw.)

† Mother–child exclusions without taking into account the father II.1.
‡ Mother–child exclusions taking into account the father II.1.

and Km, haptoglobins Hp, group specific components Gc, properdin factor B Bf and HLA.

It became evident that all four children III.1–III.4 did not fit genetically with their mother II.2 whilst there was no evidence for an exclusion of the father II.1. The systems showing mother–child exclusions without taking into account the father II.2 are listed in Table 1: III.1 is excluded by Kidd and HLA, III.2 and III.4 by ABO, PGM-1^a and HLA and III.3 by PGM-1^a and HLA. Accepting the paternity of II.1, the mother is additionally excluded from III.1–III.4 by Bf, from III.2 and III.3 by acP-1 and from III.3 and III.4 by rhesus (Table 1). Thus, the mother–child exclusions include genes governed by chromosome 1 (rhesus and PGM-1^a)[4,5], chromosome 2 (acP-1)[6], chromosome 6 (Bf and HLA)[7,8], chromosome 9 (ABO)[9], and possibly chromosome 7 (Kidd)[10]. Significantly, all the genes (or haplotypes) which must have been transmitted from the mother II.1 to her four children and which are not detectable in her blood can be found in the maternal grandparents: *O* potentially present in I.1 and in I.2, *CDe* and *Jk^a* in I.1 and I.2, acP-1 *P^a*, *Bf^F* and *HLA-A3*, *Bw35*, *Cw4* in I.2, and PGM-1^a *a*^{1} in I.2 and possibly in I.1. The four children III.1–III.4 are therefore genetically compatible with their father II.1 on the one hand and their maternal grandparents I.1 and I.2 on the other hand.

The results of unidirectional mixed lymphocyte cultures (Table 2) showed that I.2 is able to stimulate her daughter's (II.2) lymphocytes, although II.2 carries obviously in her organism both HLA haplotypes of her mother. The stimulation observed is in good agreement with a one HLA haplotype difference between both individuals. This lack of immunological tolerance demonstrates that all the cells of II.2 which express HLA-D gene products (lymphocytes, monocytes[11], epithelial[12] and endothelial cells[13]) do not possess the HLA haplotype *A3*, *Bw35*, *Cw4*.

Fibroblasts of II.2 have been cultivated from skin biopsies of both forearms. The typing results of all the markers tested for in these cells (acP-1, PGM-1^a, EsD, GLO-1 and HLA) were identical to the findings obtained using blood cells.

The karyotypes of all family members were analysed using Q-, G- and C-banding techniques. There was no evidence for numerical or structural abnormalities and, checking chromosome polymorphisms, no mother–child exclusion could be found. The mother II.2, in particular, showed in her lymphocytes and in her fibroblasts the normal female karyotype 46, XX.

Table 2 Results of unidirectional mixed lymphocyte cultures (MLC) in family Eiw. expressed in c.p.m. of ^{3}H-thymidine uptake

	Stimulators (X-irradiated)		
Responders	I.2$_X$	II.2$_X$	UR$_X$*
I.2	716	17,154	60,279
II.2	9,200	1,319	26,007
UR*	55,783	33,825	951

The numbers represent the mean value of ^{3}H-thymidine uptake in triplicate tests.
* Unrelated control person.

An interchange of all four children, *a priori* improbable, co be ruled out by interrogating the staff of the obstetric department in which the four children had been born. Furthermore the mother II.2 has no twin sibling and does not show in her circulation more than one erythrocyte and/or lymphocyte population.

The findings in this family clearly show that II.2 possesses in her organism at least two populations of genetically different cells, one demonstrable in her blood as well as in the fibroblasts, and the other one in her gonads; therefore, she must be considered a chimaera. Although the analysis of the genetic markers carried by the different cell populations of II.2 gives no evidence for the involvement of two sperms, the most simple explanation of this observation is to assume a dispermic chimaerism. The cells with the HLA haplotype *A3*, *Bw35*, *Cw4* present in the gonads of II.2 must have a rather restricted tissue distribution, as the cells of ectodermal and mesodermal origin studied do not carry the HLA-D determinant coded for by this haplotype.

Thus this family demonstrates the existence of chimaeras who do not show different populations of erythrocytes, lymphocytes and fibroblasts and can be detected only by the analysis of their progeny. Such individuals must be extremely rare, but the practical implications of this observation for problems of parentage are clear.

We thank Prim. Dr Müller-Hartburg for drawing our attention to this case, Dr H. Ludwig for skin biopsies and Dr C. Moser for the mixed lymphocyte culture.

ed-X method[3]. This yield stocks of flies in
have identical, mutagenised X chromosomes.
each stock were selected under CO_2 anaesthesia and
ed for testing 1–3 days later. To screen for mutants with abbreviated memory retention, we trained flies from each mutagenised population by exposing them 10 times to a chemical odorant, 3-octanol, in association with shock[5], then left them undisturbed for 45 min to give them an opportunity to forget. The flies were tested by running them alternately towards (1) a tube containing 3-octanol (O), the odorant they had been taught to avoid, and (2) a tube containing 4-methylcyclohexanol (M) a novel, control odorant. Figure 1 shows the number of flies which avoided each. To control for odour bias, flies which had been trained to avoid M were tested in the same apparatus. The index of learning, Λ, is the fraction of the population avoiding the shock-associated odour, minus the fraction avoiding the control odour, averaged for the two halves of the experiment. (All Λ values reported here are mean ± s.e.m. for 10 experiments.) In these conditions, wild-type flies learn and retain selective avoidance for 45 min. Seven hundred mutagenised stocks were tested; one, *amnesiac* (*amn*^{P1801}) gave reproducibly poor performance in this paradigm.

The *amnesiac* males selected above were used to breed a pure stock of mutant males and females. Male *amn* flies were mated to females carrying the X-chromosome balancer FM7a (ref. 6)

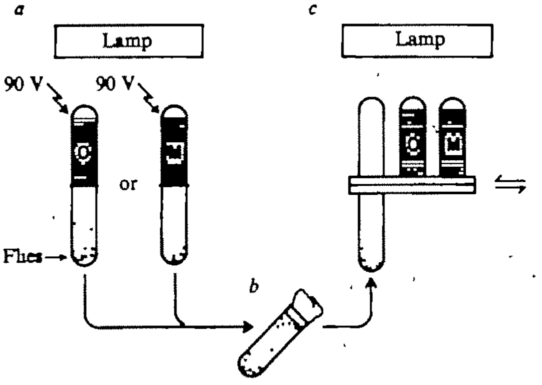

Fig. 1 Measuring memory retention of mutagenised stocks. *a*, Training: a population of 30–50 flies was taught to avoid a specific odour. The light attracted the flies from the start tube into a contiguous tube containing a chemical odorant (either 1 μl 3-octanol (O) or 2 μl 4-methylcyclohexanol (M), spread on an electrified grid (60 Hz, 90 V a.c.). After 60 s, the flies were shaken back into the start tube and another training run was begun. This cycle was repeated for 10 runs. *b*, Waiting: flies were left undisturbed for 45 min in dim light at room temperature (22 °C). *c*, Testing: the sliding counter-current apparatus[1] allowed the fresh start tube, with flies, to be shifted opposite either of two (non-electrified) grids, one spread with O, the other with M. The flies were shifted opposite the O grid and given 15 s to run, after which the flies remaining in the start tube were counted. After 45 s rest in the 'rest' tube (without grid), they were shifted opposite the M tube and their avoidance was similarly scored.

Table 1 Latent memory in normal and *amnesiac* flies

	Λ_1 (flies trained twice to same odour)	Λ_2 (flies trained to opposite odours)	$\Lambda_1 - \Lambda_2$
No anaesthesia			
C-S	0.24 ± 0.02	0.01 ± 0.03	0.23 ± 0.04
amnesiac	0.28 ± 0.03	0.03 ± 0.01	0.24 ± 0.04
Anaesthesia 30 min after first training session			
C-S	0.20 ± 0.03	0.07 ± 0.01	0.13 ± 0.03
amnesiac	0.17 ± 0.02	0.04 ± 0.01	0.13 ± 0.03

Populations were trained 10 times to avoid O or M as in Fig. 1, then left undisturbed for 45 min. Flies were then given a single cycle of training[1], which consisted of a 30-s run towards an odour (O or M) with shock, a 30-s wait, and a 30-s run towards the control odour (M or O) without shock. Thirty seconds later the flies were tested as usual. The four possible combinations of two aversive training sessions were run 10 times each. Scores from flies trained against the same odour in both sessions (O → O and M → M) were averaged to give Λ_1 values. Similarly, scores from flies trained against opposite odours (O → M and M → O) give Λ_2 values. Learning indices are calculated relative to the last training session; positive difference between the two Λ values indicates that the earlier training session affected behaviour. Such a difference is present for both normal and *amnesiac* flies. Moreover, in both genotypes, the difference persists when the flies are briefly anaesthetised 30 min after the first training sessions. Therefore cryptic memory, present in *amnesiac* flies, can be consolidated to the long-term (anaesthesia-resistant) form.

and C-S autosomes. Female FM7a/*amn* progeny were mated to *amnesiac* males, yielding F_2 progeny from which a pure stock of hemizygous *amn* males and homozygous *amn*/*amn* females could be selected by the absence of *Bar*, a dominant visible marker on the FM7a chromosome. All subsequent experiments on *amnesiac* were done with mixed males and females, 3–5 days old.

The 10-trial training procedure above is a modification of the original learning paradigm to give enhanced memory retention. It was used only for mutant screening and in genetic mapping and latent memory experiments as specified below. All other memory measurements were made using the basic olfactory paradigm of ref. 1. This is similar to the procedure in Fig. 1 except that it uses 3 training trials instead of 10, and during training, flies are alternately exposed to both O and M (one with shock, one without), to provide an internal control for sensitisation. In this olfactory paradigm the expression of learning is statistical; even in our best conditions only a third of the flies show learning in any given trial. This limits our understanding of what individual flies in the population are doing. However, we have previously found that normal C-S flies appear to be homogeneous in their capability to learn; the selective avoidance observed is not due to an 'intelligent' subset of the population[1]. A likely reason for our relatively low learning scores is that the task we have chosen—olfactory discrimination and active avoidance—is a difficult one for *Drosophila*. In fact, the flies learn much better in a simpler paradigm, as that originally developed for cockroaches by Horridge[8]. Of 25 normal individuals tested 24 (96%) consistently lifted their legs to avoid shock (data not shown).

Populations of *amnesiac* and normal C-S flies were trained in the olfactory paradigm, left undisturbed for various intervals, then tested to obtain the memory decay curves in Fig. 2. Immediate learning in the two stocks is similar, but memory in *amnesiac* flies decays rapidly and is undetectable 60 min later (avoidance of both shock-associated and control odours decreases, so that 60 min after training the behaviour of *amnesiac* is undistinguishable from that of untrained flies). In contrast, memory in C-S persists for 6 hours in these conditions[2].

Some uninteresting explanations for *amnesiac*'s forgetfulness have been ruled out. The decline in the mutant's performance is not due merely to lethargy at testing time. Populations were

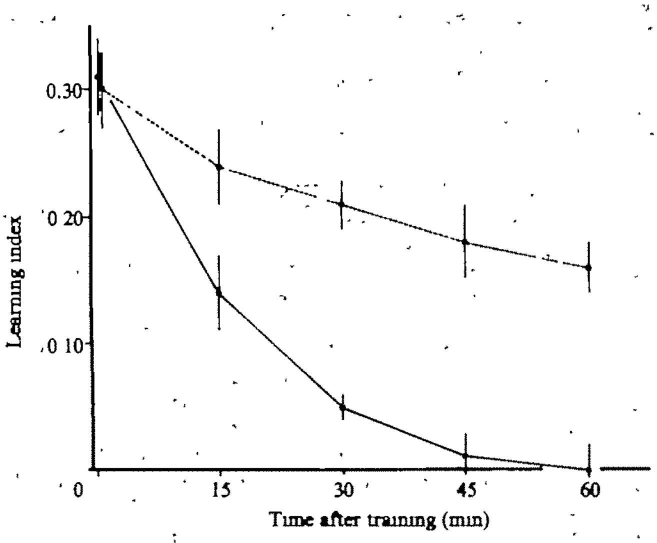

Fig. 2 Memory retention of normal (dashed line) and *amnesiac* (solid line) flies. Populations of C-S and *amnesiac* flies were given three training trials, left undisturbed for the periods indicated, then tested (procedure is as in ref. 1, except that flies were shifted to fresh tubes just before testing). The two genotypes were trained and tested simultaneously

trained, left for 45 min, then given brief (30-s) electric shock, in an attempt to re-invigourate them, and tested. The mutant still failed to demonstrate memory [$\Lambda(amn) = 0.03 \pm 0.03$, $\Lambda(\text{C-S}) = 0.15 \pm 0.02$]. To find out whether the memory decline is a result of a general deterioration in *amnesiac*'s capabilities brought on by trauma in training, flies were trained, left for 60 minutes, trained again (half to the same odour, half to the other) and immediately tested. The mutant still had normal capacity for learning ($\Lambda = 0.32 \pm 0.02$).

The sensory and motor abilities of *amnesiac* appear normal. Phototaxis as measured by countercurrent distribution[7] is similar to C-S. Mutant flies show normal avoidance of electrified grids, jump when shocked, and have normal leg-to-leg resistance of about $10^9\ \Omega$ (ref. 3). The sensitivity of *amnesiac* to the odour cues used is also similar to the parent strain. Normal flies have a slight intrinsic tendency to avoid the odorants O and M, which is overcome in the learning paradigm by strong phototactic drive toward the odour tubes. This aversion can be used to measure the flies' olfactory capability in a 'choice chamber'—a T-maze in which flies are passively transported to the choice point. One arm contains a defined amount of odorant; the other is left blank[3]. In this test, the odour avoidance behaviour of normal and *amnesiac* flies was indistinguishable. The fraction of the population which avoided O (2 μl per tube) was 0.83 ± 0.03 for *amnesiac*, and 0.81 ± 0.04 for C-S. The fraction avoiding M (2 μl per tube) was 0.65 ± 0.06 for *amnesiac*, and 0.70 ± 0.03 for C-S.

Table 2 Mapping the *amnesiac* mutation

Class	Memory (Λ) 45 min after training
Parental chromosomes:	
amnesiac	0.04 ± 0.01 ($n = 14$)
sc ec cv ct^6 *v g*^{2} *f*	0.19 ± 0.03 ($n = 27$)
Recombinant chromosomes:	
ec cv ct^6 *v g*^{2} *f*	0.21 ± 0.06 ($n = 9$)
cv ct^6 *v g*^{2} *f*	0.15 ± 0.02 ($n = 9$)
ct^6 *v g*^{2} *f*	0.10 ± 0.01 ($n = 8$)
v g^2 *f*	0.14 ± 0.01 ($n = 16$)
g^2 *f*	0.15 ± 0.03 ($n = 14$)
f	0.17 ± 0.02 ($n = 17$)
sc	-0.01 ± 0.03 ($n = 10$)
sc ec	0.06 ± 0.02 ($n = 12$)
sc ec cv	0.10 ± 0.02 ($n = 8$)
sc ec cv ct^6	0.04 ± 0.03 ($n = 9$)
sc ec cv ct^6 *v*	0.03 ± 0.03 ($n = 10$)
sc ec cv ct^6 *v g*^{2}	0.05 ± 0.03 ($n = 9$)

Memory scores, 45 min after training, are shown for parental chromosomes and each recombinant class. Each chromosome was tested over *amnesiac* in heterozygous females, to eliminate effects of markers. Recombinant chromosomes with the *forked* marker have high memory scores; chromosomes with *forked*$^+$ have low scores. This places the location of the *amnesiac* marker very close or to the right of *forked*, near the centromere of the X chromosome.

We also measured *amnesiac*'s memory using other odour cues. Flies were trained and tested as in Fig. 2, except that amylacetate and benzaldehyde[2] (both 2 μl per grid) were substituted for O and M. As before, the mutants learned normally ($\Lambda(amn) = 0.31$, $\Lambda(\text{C-S}) = 0.30 \pm 0.01$) but forgot quickly; 45 min after training $\Lambda(amn) = 0.02 \pm 0.01$, while $\Lambda(\text{C-S}) = 0.15 \pm 0.02$.

Drosophila, like higher animals, has separate memory storage phases—short-term memory, which is sensitive to cold anaesthesia, and long-term memory, which is not[2,5]. It seemed possible that the *amnesiac* mutation acted by blocking consolidation into long-term memory. Testing this idea directly is impossible, because memory in the mutant is virtually undetectable by the time consolidation would normally take place. Therefore, to lengthen *amnesiac*'s memory span, we increased the number of training trials and adopted a procedure akin to the psychological technique of 'savings measurement', in which memory can interact with more recent learning.

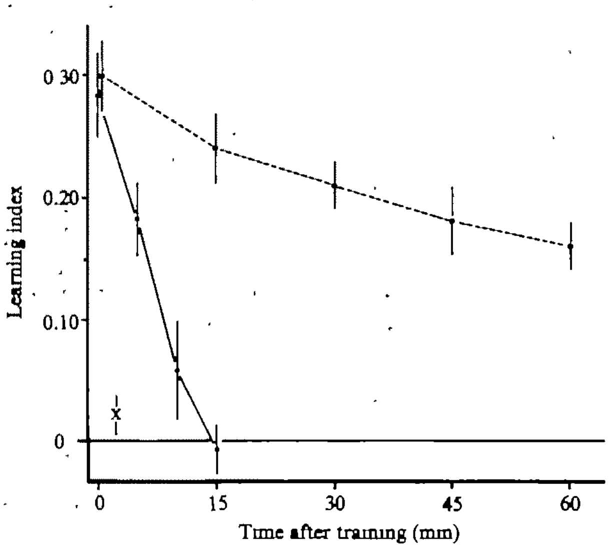

Fig. 3 Memory retention in normal flies (dashed line), *turnip* mutants (X), and *turnip*/+ heterozygotes (solid line). Method as in Fig. 2. The heterozygotes did not regain their memory later; learning indices at 20 and 60 minutes remained near zero.

We shocked flies 10 times in conjunction with either O or M, left them undisturbed for 45 min to forget, then gave them a single training run to one of the odours and tested them. All four possible combinations of the two training sessions were run, that is: O → O, M → M, O → M and M → O. If latent memory from the first training session were present to interact with learning from the final training cycle, populations which had been trained to avoid the same odour in both sessions (O → O and M → M) should show higher learning scores than populations trained in opposite directions (O → M and M → O). Table 1 shows that this was the case, for both normal and *amnesiac* flies. Moreover, for both genotypes, the effect of the first training session was largely resistant to brief cold anaesthesia applied 30 min later. The *amnesiac* mutants, like normal flies, can convert their memory into anaesthesia-resistant form; so the mutation does not block consolidation into long-term memory.

More surprisingly, Table 1 shows that in these conditions the earlier training has quantitatively similar behavioural effects in normal and *amnesiac* flies. Apparently, memory is present in the mutant. It is cryptic after the first training session, inaccessible to direct expression ($\Lambda = 0.02 \pm 0.02$) but can interact with more recent learning to affect behaviour just as in normal flies. This suggests that the *amnesiac* mutation affects memory retrieval rather than storage.

Genetically, *amnesiac* behaves as a sex-linked recessive. Memory of *amn*/+ heterozygotes 45 min after training was normal ($\Lambda = 0.18 \pm 0.03$). The mutation was mapped on the X chromosome using methods similar to those of Dudai *et al*[3]. Female *amnesiac* flies were crossed with males carrying the visible X-linked markers *scute*, *echinus*, *cut*^{6}, *vermilion*, *garnet*^{2}, *forked*. Recombinant F$_2$ males were collected and scored for the visible markers. These could not be tested directly for the presence of *amnesiac* because the markers affect the performance in learning tests. Therefore, recombinants were individually mated to *amnesiac* females, producing female progeny in which the recessive visible markers were heterozygous, and not expressed. These F$_3$ females are homozygous for *amn* if the mutation was present in the F$_2$ male; if the females forget rapidly one can infer that *amn* was present in the original recombinant. Table 2 shows memory scores of progeny from the various recombinant types. It can be seen that the *amnesiac* mutation maps near or to the right of *forked* (1–56.7) on the X chromosome. Preliminary data from a second cross suggest that *amn* lies between *forked* and *carnation* (1–62.5).

We originally set out to isolate mutants affected in memory (in contrast to those blocked in immediate learning) because memory mutations should act in the central nervous system. The fact that *amnesiac* learns in the first place indicates that its sensory and motor systems are functioning properly. Moreover, the action of memory mutations should be relatively well defined. To learn, a fly must sense cues and reinforcement, transmit the information to the proper neural centre, encode the association, and later convert it to appropriate motor output. This is a series of complex processes; a mutation could affect any of them. In contrast, memory retention requires two things—that information be stored in a relatively permanent form and that it be accessible to retrieval. We believe the *amnesiac* mutation affects one of these, probably accessibility to retrieval. Further understanding of the mutation's action on memory will depend on finding anatomical or biochemical abnormalities in *amnesiac* flies.

Gaining substantive information about memory retention will probably require more than one mutant. It is worth noting that other mutations can affect memory. Y. Dudai (personal communication) has evidence that *dunce* flies[3] store learned information in a labile form for a very short time after training. We have isolated a mutant, *turnip*(*tur*^{PS274}) which is apparently blocked in immediate learning. The heterozygote, *turnip*/+ learns normally but forgets very rapidly (Fig. 3). A plausible explanation for this situation is that the homozygote, more severely affected in retention, forgets immediately after training so that no learning can be detected.

We thank Seymour Benzer and F. X. Marble for help with the manuscript, Duncan Byers and Seymour Benzer for cantonised stocks of C(1)RM and FM7a. This work was supported by grants from the NSF and NIH. R.B. is an NIH trainee.

Interactions between *Entamoeba histolytica* and complement

THE pathogenic mechanisms in amoebiasis are not fully understood. Histopathological studies of infected tissues have shown lysis of host cells near the parasites, particularly in the liver where abscesses are formed. In the intestine, inflammatory reactions are often slight, unless there is secondary bacterial involvement. The infiltrating cells belong mainly to the lymphocyte and macrophage cell series, and neutrophil leukocytes are sparse[1], suggesting that there is a low-grade chronic inflammation. Tacheuchi and Phillips[2] have made systematic studies of experimentally infected germ-free guinea pigs, which have revealed the early events in invasive amoebiasis. When the amoebae had not yet made contact with the colonic epithelial cells, the latter showed degenerative changes such as loss of brush borders, swelling of mitochondria and dilatation of the endoplasmic reticulum. At the same time polymorphonuclear leukocytes (PMN) as well as some macrophages were seen to infiltrate the lamina propria, and extravasated erythrocytes were observed in the same areas. A high proportion of the PMN showed signs of degeneration, including disruption of the cell membrane. As changes were observed some distance from the parasites, Tacheuchi and Phillips[2] concluded that the parasites exert their effects by means of a soluble mediator(s), possibly a toxin elaborated by the parasites. Another possibility is that enzymes released from amoebae damage both epithelium and PMN. A third explanation would be that the amoebae can interact with host material to generate factors which are chemotactic for leukocytes and can also exert toxic effects. A likely candidate would be the complement system. For this reason, the experiments described here were undertaken to analyse interactions between amoebae and the complement system. IgG antibody fractions were prepared from sera of individuals suffering from amoebiasis, and unheated sera from normal humans or experimental animals were used as a source of heat-labile complement components. We found that *Entamoeba histolytica* activates complement by the alternative pathway, and can be lysed by the reaction products.

Table 1 % Of amoebae lysed by human sera in various experimental conditions

Serum	Unheated	Heated	Unheated +EDTA	Unheated +EGTA	Unheated −properdin

BH	42	3	1	51	NT
IC	39	1	3	44	NT
PH	43	2	6	46	NT
Normal rabbit	NT	3	NT	NT	NT

Hk 9 strain of *E. histolytica*, cultivated axenically. Normal human sera, lacking demonstrable antibodies, were diluted 1 : 3 without heating or after heating at 56 °C for 30 min; EDTA or EGTA were used in final concentration of 5 mM. Assays were carried out in cytotoxicity trays (Møller-Coates), using 6 μl containing about 200 amoebae. Assays were carried out in quadruplicate using 0.1% trypan blue, counting a total number of 400–500 cells. Sera were depleted of properdin by affinity chromatography on an anti-properdin-activated Sepharose column at 4 °C in the presence of 10 mM EDTA (ref. 14) which was later removed by dialysis in the cold. After this procedure the serum was still capable of lysing amoebae in the presence of antibodies.

Two strains of *E. histolytica*, Hk 9 and NIH 200, were grown in culture. When amoebae from either one of these strains was incubated in fresh human serum without detectable antibodies, a high proportion of the amoebae were lysed, as shown by marked morphological changes, including disruption of the cell membrane and expulsion of nuclei. These results were

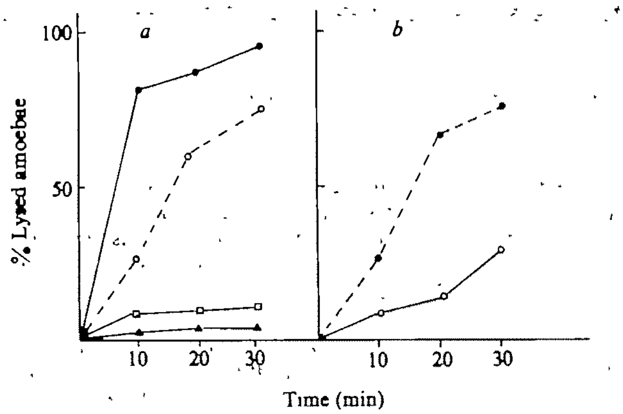

Fig. 1 % Dead amoebae (Hk 9) after incubation for 10, 20 and 30 min with unheated or heated normal human serum diluted 1:2 in phosphate-buffered saline, pH 7.4, containing Ca^{2+} and Mg^{2+} (PBS) *a*, ●, Amoebae preincubated for 30 min at 4 °C with the IgG fraction of a human serum containing antibodies to *E. histolytica*. The fraction was obtained by ion-exchange chromatography on a DEAE Sephadex A50 column. Immunofluorescence with class-specific antiglobulin conjugates showed an IgG titre of 40, IgM and IgA negative. After interaction with IgG antibodies, fresh unheated human serum with no detectable antibodies was added to give a final dilution of 1:2. ○, Amoebae preincubated at 4 °C for 30 min in PBS followed by reaction with unheated serum. □, Preincubation with IgG antibodies followed by heated serum. △, Preincubation in PBS followed by heated serum. *b*, ○, Preincubation with IgG antibodies followed by unheated serum + 5 mM EGTA. ●, Preincubation without antibodies followed by unheated serum + 5 mM EGTA.

confirmed by the release from prelabelled cells into the medium of either ^3H-uridine or ^{14}C-α-isobutyric acid. However, the use of isotopes was somewhat less sensitive, as well as less convenient, than morphological observations, and for most experiments the latter were used. The lysis was inhibited by 5 mM EDTA, which chelates both Ca^{2+} and Mg^{2+} ions, but not by 5 mM EGTA, which selectively chelates Ca^{2+} ions. When sera were depleted of properdin, lysis did not occur (Table 1). Lysis was efficient in the presence of $\geqslant$50% normal guinea pig serum as well as C4-deficient guinea pig serum, in which there is a complete block of the classical pathway (Table 2).

Two distinct effects of antibodies were demonstrated. If amoebae were incubated with the IgG fraction of an antiserum and then with unheated serum, accelerated lysis was observed, presumably due to classical pathway activation. However, the lysis occurring in the presence of EGTA was markedly inhibited (Fig. 1). This may be due to steric hindrance by antibodies of access to groups on the amoeba surface with alternative-pathway activating properties.

Immunofluorescence showed the presence of C3 or a derivative with the same immunological reactivity on the surface of the amoebae. Capping followed by endocytosis occurred in a similar way to that described by Aust Kettis and Sundqvist[3] in their studies of the capping of specific antibodies on the surface of *E. histolytica*.

These observations demonstrate that *E. histolytica* is able to activate complement by the alternative pathway and that the parasites can be lysed by the reaction products. Furthermore, sera from rabbits congenitally deficient in C6 gave markedly reduced lysis compared to sera from normal rabbits, and depletion of normal human serum of C5 by affinity chromatography abolished its capacity to lyse amoebae. These findings indicate that lysis is due to the terminal complement components (C5–C9).

Serum dilutions higher than 1:10 resulted in very little lysis. Experiments were designed to ascertain whether such sub-lytic concentrations of complement might stimulate amoebae to increased secretion of hydrolytic enzymes in a manner analogous to the secretion-stimulating effects of immune complexes[4] and isolated C3b (ref. 5) on macrophages. In repeated experiments it was found that both the total concentration and release of the acid hydrolase *N*-acetyl-β-D-glucosaminidase (NAGase) were increased in amoebae which were grown in the presence of 5–10% unheated serum, in contrast to comparable amounts of heated serum (Fig. 2).

The relevance of these observations to the pathogenesis of amoebiasis is not yet known. Activated complement may participate in defence against amoebae. Nevertheless, despite the lytic effect of complement, *E. histolytica* can in many instances survive in the tissues. Continuous turnover of parasite cell membrane components accompanied by change in distribution of complement receptors may contribute to their survival in the host. Moreover, in the intestinal wall the concentration of active complement components may be at the limit of what is required to lyse the parasite. In this situation complement cleavage products, such as C3b, might stimulate the amoebae to increased production and release of hydrolytic enzymes. Such enzymes

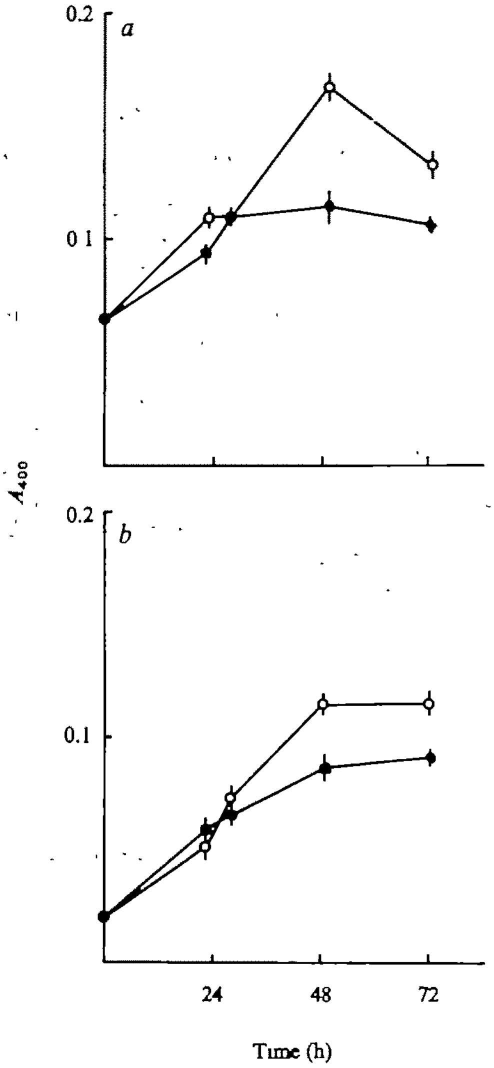

Fig. 2 *a*, Total amount of NAGase per 1000 amoebae; *b*, amount of enzyme released into the medium per 1000 amoebae. *E. histolytica* (NIH 200) was cultured in 1.8-ml glass tubes with screw caps (PBG-Trident) in medium TPS-1 with the addition of either 10% heat-inactivated or 5% heat-inactivated and 5% unheated human serum. At 22, 28, 49 and 72 h four tubes in each series were chilled in an ice bath, shaken in a whirl mixer and 1 ml removed for parasite counting in a Coulter Counter Industrial B. The remainder were centrifuged for 5 min at 1,500 r.p.m. Enzyme assay according to Woollen *et al.*[15] was carried out on supernatants and cells. ●, 10% heated human serum; ○, 5% heated + unheated normal serum.

seem to be involved in the pathogenesis of many chronic inflammatory conditions[6], and the combined effects of activated complement, leukocyte products and amoebic enzymes probably contribute to the lytic and reactive changes observed in the tissues of patients with invasive amoebiasis.

Table 2 % Of amoeba lysed by normal and C4-deficient unheated and heated guinea pig serum in various experimental conditions

Serum	% Dead parasite cells
Unheated	57
Unheated + EDTA	2
Unheated + EGTA	75
Heated	5
C4 deficient, unheated	54
C4 deficient, heated	3

E. histolytica strain NIH 200 was incubated with 3:4 dilutions of guinea pig sera. Other experimental conditions as for Table 1.

Capacity to activate complement by the alternative pathway has also been reported for other parasites, including *Trypanosoma cruzi*[7,8], African trypanosomes, including the variant-specific antigen[9–11], and *Schistosoma mansoni*[12]. Schistosomula incubated with normal serum activate complement by the alternative pathway, and the C3 on the surface of the parasites allows attachment of eosinophils and killing of the parasites[13]. Hence, activation of complement by the alternative pathway can not only lyse parasites directly, as described here for enteropathic amoebae, but also render parasites susceptible to complement-dependent cell-mediated lysis. Complement activation, presumably initiated by surface glycoproteins of parasites, may be a relatively common phenomenon, contributing on the one hand to host protection and on the other hand to the pathogenesis of parasitic diseases.

Sera from rabbits congenitally deficient in C6 were obtained from Professor K. Rother, goat anti-human C5 serum was provided by Dr D. R. Schultz, strains of *E. histolytica* by Dr L. Diamond, absorbed rabbit anti-properdin serum by Dr C. O. Kindmark, and C4-deficient guinea pig serum by Dr P. Lachmann.

HLA and testicular cancer

HLA IS involved not only in transplantation, but is also associated with many disease states. This first became evident when the major histocompatibility complex of the mouse (H-2) was shown to play a major part in determining resistance to Gross leukaemia virus[1]. Subsequent studies in both animals and man have shown that many disease states are associated with, and perhaps regulated by, the major histocompatibility complex[2,3]. We now present the tissue typing results from a group of patients with testicular cancer. The results show an abnormally high antigen frequency for HLA-Dw7 in patients with testicular teratocarcinoma.

The study population consisted of 61 patients from the University of Minnesota. Thirty patients had seminoma, 27 had embryonal cell carcinoma, 26 had teratocarcinoma, and 7 patients had choriocarcinoma (some of the patients had mixed tumours). All patients had completed treatment (surgery, radiotherapy, and/or chemotherapy) and were clinically free of disease at the time of testing. Peripheral blood lymphocytes were obtained on each individual by Ficoll–Hypaque density centrifugation[4] and frozen at a controlled rate in 10% dimethyl sulphoxide and RPMI 1640 with 25 mM HEPES (Microbiological Associates) supplemented with 20% pooled human serum (PHS), heparin (20 IU ml^{-1}), L-glutamine (0.2 mg ml^{-1}), streptomycin (100 μg ml^{-1}) and penicillin (100 IU ml^{-1}). The cells were stored in vapour phase liquid nitrogen until ready for analysis at which time they were thawed rapidly at 37 °C and diluted with 5% PHS, washed twice, and resuspended in culture media for testing. All cells were tested for 52 HLA-A, HLA-B and HLA-C specificities by the NIH standard technique[5]. HLA-D assignments were made by homozygous typing using at least 22 typing cells covering all HLA-D specificities except HLA-Dw8 and HLA-Dw9. Homozygous typing was performed in round-bottomed microtitre plates using 5×10^4 responders and 5×10^4 stimulator typing cells inactivated with 5,000 rad from a ^{137}Cs source (3.2 min). Cells were suspended in 0.2 ml of 20% PHS and incubated in a 37 °C, 5% CO_2 and air atmosphere for 6 days. They were then terminated immediately after a 6-h pulse with 1.0 μCi ^3H-TdR (6.7 Ci $mmol^{-1}$, NEN). Cells were collected on an automated harvester. Results were 'double-normalised' and typing responses were assigned to those cells that gave less than 35% DNV. The reactivity of patient cells was checked by stimulation with purified PHA (HA-17) (Wellcome), and only those patients responding in the same range as normal control cells (typed simultaneously with the tumour patients) were included for the HLA-D typing results. Antigen frequencies were then calculated for the tumour group as a whole as well as for each of the groups of patients with seminoma, embryonal cell carcinoma and teratocarcinoma, and compared to normal control values ($n = 561$ for HLA-A and HLA-B, 171 for HLA-C and 150 for HLA-D specificities) obtained from a random population of the same geographical area as the tumour patients. Significance was determined by χ^2 analysis and P values were corrected to account for chance significance; $P < 0.01$ was considered significant[6].

The antigen frequency of HLA-Dw7 was significantly increased in the teratocarcinoma group (12/26, $P < 0.01$) as compared to normal control values (14/150) (Table 1); the difference, however, was not detected in either of the seminoma (7/24, not significant), choriocarcinoma (0/7, NS) or embryonal cell carcinoma groups (7/24, NS) or the total patient group (15/53, NS). (Six patients were eliminated from the original seminoma group (30) and 3 patients from the original embryonal carcinoma group (27) for HLA-D typing because of inadequate reactivity to HA-17.) The relative risk (which is a calculated term that represents the risk of developing a disease in an individual possessing a particular HLA antigen as

Table 1 Frequency of HLA-D determinants in patients with testicular teratocarcinoma and controls

Determinant	Normal controls (%)	Patients with teratocarcinoma (%)	*P* value
Dw1	19/150 (13)	7/26 (27)	NS
Dw2	19/150 (13)	3/26 (12)	NS
Dw3	21/150 (14)	6/26 (23)	NS
Dw4	12/150 (8)	2/26 (8)	NS
Dw5	7/100 (7)	1/26 (4)	NS
Dw6	0/50 (0)	1/26 (4)	NS
Dw7	14/150 (9)	12/26 (46)	<0.01
Dw10	5/150 (3)	0/26 (0)	NS
Dw11	18/150 (12)	0/26 (0)	NS
Single blank	69/168 (41)	8/26 (31)	NS
Double blank	30/168 (18)	6/26 (23)	NS

HLA-D typing was performed as described in the text. Lymphocyte responsiveness for each patient was checked by response to purified PHA (HA-17). 5×10^4 cells were incubated in 0.2 ml of 1:100 HA-17. Cultures were terminated at 96 h immediately after a 6-h pulse with 1.0 μCi ^{3}H-TdR (6.7 Ci mmol^{-1}) Only those cells responding in the range of normal controls were included in the HLA-D typing results. All HLA-Dw7 assignments were made by typing responses to HTC JB-12 (submitted to the Seventh International Histocompatibility Workshop, Oxford, as 7w542) and HTC 56 (submitted as 7w534). One teratocarcinoma patient was assigned HLA-Dw1, Dw6, Dw7 and included in the HLA-Dw7 group; however, if this patient were excluded from analysis, the increased HLA-Dw7 antigen frequency would still be significant (11/25, $P<0.01$). NS, not significant

compared to an individual lacking that antigen) between HLA-Dw7 and teratocarcinoma was 8.32. The association between HLA-Dw7 and teratocarcinoma, although statistically significant, should be interpreted with the understanding that the HLA-D assignments are based on reactivity of responder (tumour patients') T cells which can be affected by the presence of cancer as well as its various modes of treatment. In order to reduce this source of error, lymphocyte reactivity from each study patient was checked with purified PHA (HA-17) and only those responding in the same range as normal control cells were included in the HLA-D typing results.

The biological significance of this as well as other disease associations with HLA is, as yet, unknown. However, four possible mechanisms have been suggested. (1) HLA antigens may cross-react with pathogen antigens leading to cross-tolerance; the pathogen, then would not be subjected to the host's immune mechanisms. (2) HLA antigens may function as cell surface receptors for particular pathogens similar to the association between malaria susceptibility and Duffy red blood cell antigens[7]. (3) There may be a genetic linkage between genes controlling the expression of HLA antigens (which serve as markers) and genes controlling immune responsiveness of the host and likewise, (4) HLA antigens may serve as markers for specific genes causing deficiency of specific normal proteins similar to the HLA linked genes regulating levels of second and fourth components of complement[8].

Irrespective of which of these mechanisms apply, the association between HLA and testicular teratocarcinoma is especially interesting for two reasons—first, it has been suggested that heredity may be an aetiologic factor in the development of testicular cancer because at least 18 cases of familial testicular cancer have been reported[9]. And second, there is a relationship between teratocarcinoma and H-2 in the mouse[10]; specifically, the H-2 linked T/t complex which exerts control over embryonic differentiation, male reproduction including sterility and transmission ratio distortion, and crossing over frequency between T/t and H-2 (refs 11, 12) also controls the expression of an embryonic antigen, F9, that is expressed on adult teratocarcinoma cells[13,14]. In addition, the F9 antigen is similar to H-2 antigen in molecular weight and subunit structure and may, in fact, represent an embryonic equivalent of histocompatibility antigens[15].

The association between the human major histocompatibility complex (HLA) and testicular teratocarcinoma is therefore of interest considering the homology between mouse and the human major histocompatibility complex. First, because F9 and H-2 K and D region antigens have closely associated molecular and subunit structures[15], a similar teratocarcinoma associated antigen in the human may cross-react with HLA (HLA-Dw7) leading to a state of 'cross-tolerance' which would support one of the theories of HLA and disease association. Second, considering the established relationship between the major histocompatibility complex, the T/t complex, and teratocarcinoma in the mouse system, a relationship between HLA-Dw7 and teratocarcinoma may add support to the existence of a MHC linked 'T/t like' region in the human. This concept is further supported by the association between HLA and spina bifida which may be considered to have morphological similarities to those controlled by the T/t complex. In addition, there are antigens cross reacting with F9 on human sperm[17] as well as on human teratocarcinoma[18].

Thus, in the mouse there is a structural and developmental association between a teratocarcinoma associated antigen (F9) and the major histocompatibility complex. The association of HLA-Dw7 with testicular teratocarcinoma could lead to similar studies in the human that will further explain the function of the human major histocompatability complex.

Specific antibody-secreting cells generated from cells producing immunoglobulins without detected antibody function

STUDIES of immune responses in rabbits, rats and mice have led us to describe a population of differentiated immunocytes synthesising and secreting immunoglobulins without detectable antibody function for the antigens injected[1] (IFC). These cells were antigen induced and appeared before the antibody-forming cells (AFC). The proliferation of IFC after antigenic stimulation can be explained by several hypotheses, the most plausible being that antigen-stimulated T cells release nonspecific factors which trigger clones of B cells bearing membrane receptors unrelated to the inoculated antigen. Such an explanation has been advanced by several authors[2,3] but experiments performed in our laboratory do not support such polyclonal activation. Indeed, some cells contained both antibodies and immunoglobulins without detectable antibody function in different areas of their cytoplasm[1,4]. Furthermore, some common idiotypic specificities were expressed by both AFC and IFC (ref. 5). Based on these findings, and additional studies on the developmental kinetics of IFC and AFC in animals with different immunological status, which indicate that there is a close relationship between these two cell populations, we put forward the hypothesis that AFC might be recruited among IFC. That is, that these two cell types represent two stages of differentiation of the same cell population. To test this assumption directly we performed experiments at the single cell level with micromanipulated and individually cultured IFC and found that at least some of these cells generate specific AFC.

Adult C57BL/6 strain mice were immunised by injection of horseradish peroxidase (PO) emulsified in Freund's complete adjuvant into both hind footpads. Six days later, cell suspensions were prepared from their popliteal lymph nodes and tested for the presence of AFC and IFC. Anti-peroxidase antibody-secreting cells (AFC) and immunoglobulin-secreting cells were detected by Cunningham's[6] and reverse[7,8] local haemolysis plaque assays respectively (see legend to Table 1). At this time, 801 ± 301 IFC per 10^6 viable lymph node cells were present, but no AFC were found. The lymphoid cells were mass cultured for 24 h to select the most resistant cells under *in vitro* conditions. After this culture, the number of IFC did not vary and very few anti-PO and anti-sheep red blood cell (SRBC) AFC appeared (Table 1). Some of these IFC were micromanipulated, transferred into separate wells of polyacrylamide rafts[14,15] and individually cultured in the conditions described in Table 2, in the presence of irradiated syngeneic splenocytes or thymocytes as feeder layer and horse red blood cells covalently linked with PO (HRBC–PO) as stimulating antigen. The scarcity of indirect anti-PO and anti-SRBC AFC detected at the time of micromanipulation made it highly improbable that such PFC would be micromanipulated (Table 1). Almost all the micromanipulated cells can therefore be considered as cells really secreting immunoglobulins without detectable antibody function.

Table 1 Number of IFC, anti-peroxidase and anti-SRBC AFC per 10^6 viable lymph node cells after 24 h of mass culture*

IFC	Anti-peroxidase AFC Direct plaques	Anti-peroxidase AFC Indirect plaques	Anti-SRBC AFC Direct plaques	Anti-SRBC AFC Indirect plaques
872 ± 474	1 ± 4	4 ± 6	1 ± 2	1 ± 3

C57B1/6 mice were injected in both hind footpads with 250 μg of horseradish peroxidase (PO) emulsified in Freund's complete adjuvant and killed 6 d later. Popliteal lymph nodes were removed, teased and cells were mass cultured in conditions reported in detail previously[9–11]. Briefly, 8×10^6 viable lymphoid cells were cultured without shaking in 35 mm Petri dishes containing 2 ml Click's medium[12] supplemented with LPS (*Escherichia coli* 055B5 lipopolysaccharide, Difco) at a final concentration of 4 μg ml^{-1} and with PO covalently linked to horse red blood cells[13] (HRBC–PO, 5×10^6 per dish). The cells were collected 24 h later and the anti-PO, anti-sheep red blood cell (SRBC) AFC and immunoglobulin-secreting cells were detected by local haemolysis plaque assay, the indicators used being either SRBC covalently coupled to PO (ref. 13), SRBC or SRBC coated with rabbit hybrid antibody $(\text{Fab}')_2$ fragments with dual specificity to SRBC and mouse immunoglobulins (refs 7, 8). SRBC adsorbed guinea pig serum was used as source of complement. To reveal the indirect AFC and immunoglobulin-secreting cells, a rabbit anti-mouse Ig antiserum was added to the mixture (final dilution used: 1/400).

* Arithmetic means of 19–24 different experiments ± one standard deviation. In each experiment the lymph nodes of 5–12 mice were pooled.

Table 2 Percentage of IFC which generate anti-PO AFC or which change into anti-PO AFC

No. of micromanipulated IFC	Presence(+) or absence(−) of peroxidase inhibitor	No. and percentage (in parentheses) of wells containing AFC after 48 h of microculture	Total no. of haemolytic plaques detected with SRBC–PO after 48 h of microculture
392	−	90 (23)	345
119	+	2 (1.7)	3

Lymphoid cells were collected after 24 h of mass culture (see legend to Table 1). Revealed IFC were micromanipulated from the centre of haemolytic plaques by a previously described procedure[10,11] and transferred into separate wells of polyacrylamide plates previously seeded with 10^3 to 10^4 irradiated (1,500 rad) normal C57BL/6 mouse splenocytes or thymocytes as feeder layer and 10^3 to 5×10^3 HRBC–PO as antigen. The medium used for the microculture was composed of 50% fresh Click's medium and 50% previously filtered supernatant of the mass culture. After 48 h of microculture, the content of each well was removed and mixed with SRBC–PO and complement. Cells lysing these red cells were detected by Cunningham's haemolysis plaque assay. The specificity of the molecules secreted by the progeny of microcultured cells capable of lysing SRBC–PO was tested in control experiments by adding soluble peroxidase as inhibitor to the revealing mixture (final concentration 70 μg ml^{-1}).

After 48 h of culture, 90 out of 392 micromanipulated IFC (23%) were transformed (in 34% of positive wells only one haemolytic plaque was detected) into cells able to lyse SRBC–PO or generated daughter PFC lysing these erythrocytes. Only some of the individually cultured cells yielded a PFC progeny. In

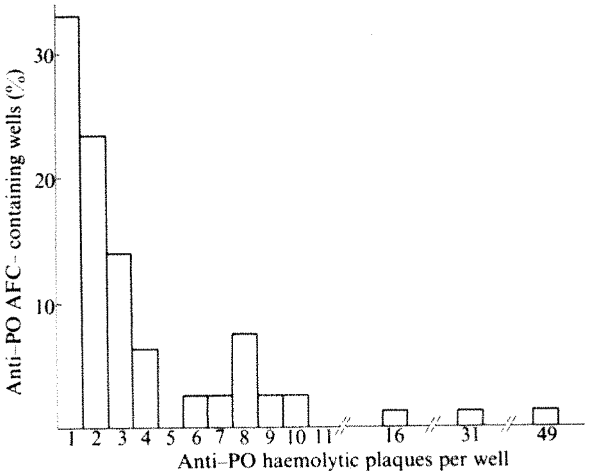

Fig. 1 Distribution of the number of anti-PO haemolytic plaques found in each positive well seeded 48 h before with a single micromanipulated IFC.

0028-0836/79/0277—0218$01.00

previous experiments of this type, about 10–20% of parental PFC generated daughter PFC (refs 11, 15) the others could be either terminal cells, cells generating memory cells or cells injured by micromanipulation procedure. It has been shown[11] that PFC are derived from micromanipulated cells and not from the irradiated cells used as the feeder layer, and this was further tested in the present study (unpublished results). Thus, no anti-PO AFC was found in wells containing only irradiated splenocytes or thymocytes and HRBC–PO, irradiated splenocytes or thymocytes used as the feeder layer were equally effective for the generation of AFC from IFC, and if the number of irradiated splenocytes was varied from 10^3 to 10^4 cells per well, the same percentage of wells containing anti-PO AFC was found.

Of the wells containing anti-PO AFC, 66% had more than one haemolytic plaque (see Fig. 1). Often, the centre of large haemolytic plaques contained several clustered cells. It is therefore likely that one or more divisions of the micromanipulated cells were needed before the secretion of anti-PO antibodies by the daughter cells could be detected.

Table 3 Some AFC derive from IFC. This event requires the presence of the immunising antigen

No. of micromanipulated IFC	Presence or absence of PO in the microculture	No. of wells containing AFC after 48 h of microculture	Total no. of haemolytic plaques detected on SRBC–PO after 48 h of microculture
110	HRBC–PO	30 (27.3%)	174
127	HRBC	2 (1.6%)	8

Micromanipulated IFC were transferred into separate wells of polyacrylamide rafts containing 5×10^3 irradiated (1,500 rad) normal C57BL/6 mouse splenocytes and either 2.5×10^3 HRBC–PO, or 2.5×10^3 native HRBC. For conditions of the microculture and detection of daughter PFC see Table 2.

The specificity of the antibody secreted by the daughter cells lysing the SRBC–PO was checked by adding soluble peroxidase in the revealing mixture. In these control experiments, only 2 out of 119 wells tested contained 3 haemolytic plaques, (compared to 90 out of 392) (Table 2). The 97% inhibition of haemolytic plaques when soluble peroxidase was present in the revealing mixture and the absence of antigenic determinants shared by SRBC and PO (ref. 8 and unpublished results) demonstrate that cells lysing the SRBC–PO were true anti-PO antibody producers.

To determine whether the presence of the immunising antigen was critical to the generation of AFC from IFC, some of the latter cells were micromanipulated and transferred to wells containing irradiated cells and native HRBC (Table 3). Control experiments where IFC were microcultured into wells containing HRBC–PO, were run simultaneously. Only the IFC cultured in the presence of HRBC–PO generated a large number of anti-PO AFC. In contrast, very few anti-PO haemolytic plaques were detected in wells seeded with native HRBC (25 times less).

The experiments reported in the present paper clearly demonstrate that some IFC taken from mice immunised with PO generate anti-PO AFC or change into anti-PO AFC. This event seems to be associated with one or several cell divisions and requires the presence of the antigen. It appears, therefore, that IFC and AFC do represent different stages of differentiation of the same cell population. One explanation is that IFC and precursors of IFC are monopotent cells, that is, there is only one antibody-forming potentiality per cell, the IFC synthesising and secreting non-functional precursors of antibodies. Such an explanation is not substantiated by the biochemical study we have performed on these cells[16]. Indeed it has not been possible to detect any particular composition or molecular weight for the immunoglobulins synthesised by the IFC. Furthermore the finding that the presence of the antigen is required for this step of differentiation to occur makes this type of explanation improbable. Alternatively IFC and precursors of IFC may be multipotent cells, that is, they synthesise and secrete immunoglobulins with multiple specificities. During differentiation, and under the selective influence of the antigen, they acquire a specialisation, that is, they synthesise monospecific antibody molecules. The finding that the presence of the antigen is required for this step of differentiation to occur lends further weight to such a view. This event may require genetic rearrangement, occurring during cell division.

Murine embryonic B lymphocyte development in the placenta

B LYMPHOCYTES derive from pluripotent stem cells which give rise to erythrocytes, granulocytes, monocytes, macrophages and T and B lymphocytes[1,2]. Stem cells have been found in yolk sac, fetal liver, bone marrow, spleen and blood. During ontogeny from stem cells to mature B cells, precursor B cells (pre-B cells) can be found. Various types of pre-B cell can be identified. There are those which already produce and release immunoglobulin (Ig), but which are morphologically different from mature B cells[3,4]. Using surface-bound Ig as a marker for the development of mature B cells, it has previously been found that fetal liver, but not yolk sac, could develop mature B cells *in vitro*[5,6]. A second type of pre-B cell can be characterised functionally as not being reactive to antigen or mitogens but which, on adoptive transfer into irradiated recipients or following *in vitro* culture, develops into a reactive cell[7–9]. When stimulated by antigens or mitogens, such mature, reactive surface Ig-bearing resting B lymphocytes develop into IgM-, IgG-

(H-2^d)	(Reduction)		(97%)	(12%)
Spleen (adult, F1)				
(C57BL/6J × DBA/2J)F$_1$		920 ± 120	90 ± 30	40 ± 20
(H-2^b × H-2^d)	(Reduction)		(90%)	(95%)

* Duplicate aliquots of the IgM-secreting PFC at the peak of the response were first incubated with C57BL/6J (anti-DBA/2J spleen cell) serum (H-2^b anti-H-2^d) or with DBA/2J (anti-C57BL/6J spleen cell) serum (H-2^d anti-H-2^b) (both gifts from Dr H. von Boehmer) for 30 min on ice, thereafter washed and then incubated with appropriately diluted rabbit complement for 30 min at 37 °C. Finally, the number of IgM-secreting PFC was determined in the protein A-SRC plaque assay[11]. PFC were treated this way for placenta cell cultures (at day 12 of gestation) at time equivalent to the time of birth (day 19 of gestation) in culture, and at day 5 of culture for spleen cells grown from 3×10^5 cells ml^{-1} in the presence of LPS.

and IgA-secreting plasma cells, which can be detected using a haemolytic plaque assay as plaque-forming cells (PFC)[10,11]. Pre-B cells which develop into antigen- or mitogen-reactive cells have been localised in fetal liver, bone marrow and spleen. The earliest that pre-B cells had previously been identified during embryogenesis of the mouse was at about day 12 or 13, but I report here the detection of IgM- and IgG-secreting PFC in mitogen-stimulated cultures of single cell suspensions of mouse placenta 9–14 d old. Placenta is thus identified as a new site of B-lymphocyte development which, during embryogenesis, precedes B-cell generation in fetal liver.

The culture technique used facilitates *in vitro* development of pre-B cells from the placenta to mature B-cells which can subsequently be stimulated by the B-cell mitogen lipopolysaccharide (LPS) to IgM- and IgG-secreting cells. Placentae were obtained from timed pregnant C57BL/6J female (H-2^b) mice, mated with DBA/2J male (H-2^d) mice. The embryo was first removed from the uterine wall and then the ectoplacental cone was dissected away from the uterus, and thereafter, from the yolk sac and embryo. They were rinsed extensively with balanced salt solution (BSS) and then dispersed into single cell suspensions by cutting the cones into small pieces with scissors, followed by passaging of the placental pieces through a stainless screen (200 mesh) with the aid of the piston of a 5-ml plastic syringe. After washing three times with cold BSS, the placental cells were suspended at 5×10^6 cells ml^{-1} in medium containing LPS. Culture conditions were those described previously for fetal liver cells[8], except that dextran sulphate was added. The addition of dextran sulphate increased the total LPS-induced IgM-PFC response of placental cells five- to tenfold (details to be published elsewhere), but the development of IgM- and IgG-PFC in cultures of placental cells was still dependent on the presence of the B-cell mitogen LPS.

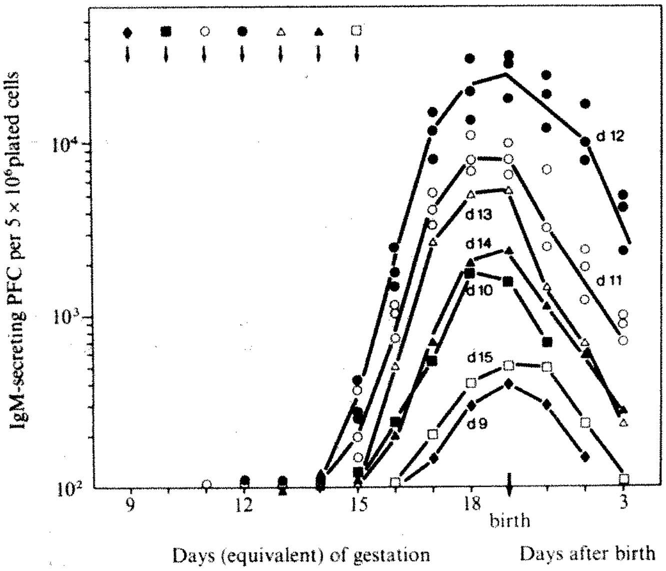

Fig. 1 The development of IgM-secreting PFC (determined with the protein A-SRC assay[11]) in suspension cultures of placenta at different stages of gestation (◆, day 9; ■, day 10; ○, day 11 (3 experiments); ●, day 12 (3 experiments); △, day 13; ▲, day 14) in the presence of dextran sulphate (100 μg ml^{-1}; MW 500,000; Serva) and LPS (50 μg ml^{-1}; a gift from Drs C. Galanos and O. Lüderitz, Max-Planck Institut fur Immunbiologie, Freiburg, West Germany) assayed at various days during culture.

Cells obtained from placenta at any time during gestation (between days 9 and 14) yielded a peak of IgM-secreting PFC in culture at the time corresponding to day 19 of gestation (Fig. 1). This was followed by the peak of IgG-secreting PFC 2–5 d later (not shown). As shown previously[8], the largest number of IgM-secreting PFC developing from mature B-cells is usually observed in such cultures 4–5 d after mitogenic stimulation. If it is assumed that maturation of B cells from placenta *in vitro* parallels in time their maturation *in vivo*, then placental cells, kept either *in vivo* or *in vitro*, acquire LPS reactivity probably at the equivalent of days 14–15 of gestation. The highest number of precursor B cells was observed in placental cells removed on day 12 of gestation, as estimated by the total number of PFC obtained in the mitogenic response (Fig. 1).

The majority of all IgM-secreting PFC developing in placental cell cultures expressed the embryonic H-2^b and H-2^d haplotypes (Table 1) following LPS stimulation. This excludes the possibility that the LPS-reactive cells were contaminating maternal (H-2^b) cells.

The frequency with which precursor cells in the placenta developed LPS reactivity and then into IgM-secreting PFC in culture, was determined by limiting dilution analyses in the presence of rat thymus 'filler' cells (3×10^6 per ml) (ref. 9). Placental cells at day 10 of gestation contained one precursor in 2×10^4 cells; at day 11, one in 4×10^3; at day 12, one in 8×10^2; at day 13, one in 5×10^3; and at day 14, one in 10^5 cells. Placenta, therefore, precedes fetal liver as an organ of embryonic B-cell development by several days[9]. As placental B-cell development declines, it rises in fetal liver (Fig. 2).

B-lymphocyte development in the mammalian embryo has been recognised to be multifocal. Furthermore, it is now evident that the sites of B-lymphocyte development change with the stage of embryogenesis. A first wave of B-cell differentiation in the placenta up to day 12 of gestation is followed by a second wave in fetal liver, which continues to birth. Thereafter, spleen and bone marrow take over as major sites of B-cell development. Placental B-cell generation begins concomitantly with the development of blood islands in yolk sac and ceases (at day 12) when haematopoiesis ceases in the yolk sac. Placenta and yolk sac are in intimate association during this time of embryogenesis[12]. It is, therefore, possible that pluripotent stem cells or B-cell precursors migrate from yolk sac to placenta for further differentiation along the B-cell pathway.

Yolk sac is known to contain pluripotent stem cells from which mature erythrocytes, granulocytes, monocytes, megakaryocytes and lymphocytes arise by differentiation. Cell-marker experiments have shown that stem cells migrate, and are thereby seeded into embryonic myeloid organs and primary lymphoid organs, such as fetal liver, bone marrow, spleen and thymus[13]. Stem cells themselves are thought to be uncommitted; it has been suggested that their differentiation into the various types of blood cells depends on the inductive influence of the organ rudiment into which they migrate[14]. In avian blood cell differentiation, it is possible that the epithelium of the bursa of Fabricius could have such an inductive effect, although there is no indication as to the genetic loci which may control the expression of the inducing signals on such epithelial cells. Neither is anything known of the possible genetic control of murine B-cell development through genes controlling the expression of B-cell differentiation-inducing signals. If such differentiation-inducing structures exist, they are probably expressed on mesenchymal-endodermal elements[15] of placenta, fetal liver, bone marrow and spleen. B-cell differentiation in the placenta, however, may offer embryonic stem cells the possibility to differentiate in response to signals which are encoded in the maternal genes, expressed on maternal endoderm within the placenta.

The site of B-cell differentiation certainly does not depend on the site of stem-cell generation. Stem cells could migrate to the placenta either from yolk sac[13] or from another embryonic site[16], particularly since the embryo, at day 9 of gestation, has developed a heart and a circulatory system in which cells can migrate from yolk sac to embryo and to placenta and back.

The ability of placental cells from as early as day 9 of gestation to differentiate into mature B-cells *in vitro* offers exciting new experimental possibilities of probing the repertoire of variable regions of heavy and light chains, expressed very early in embryonic development, which may be close to or identical to the repertoire carried in the germ line. If cellular contact between stem cells and 'environment' is needed for B-cell differentiation, then the rudiment of placenta may be one of the earliest sites on which B-cell differentiation occurs.

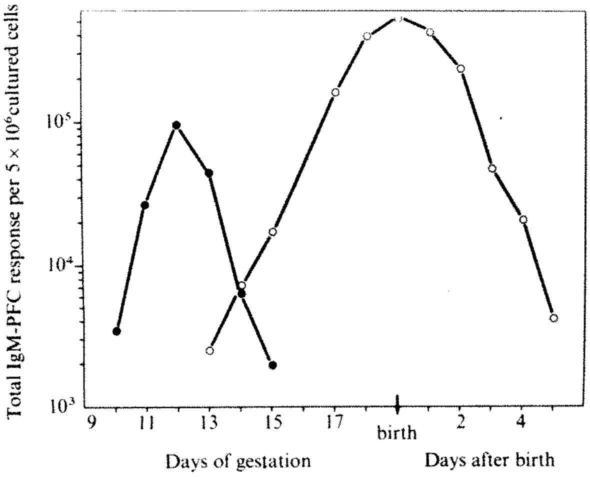

Fig. 2 LPS responsiveness of placentae (●) and fetal liver (○) (see ref. 9) cells taken in culture in the presence of LPS at different stages of development. IgM-secreting PFC responses were determined each day from the equivalent of day 15 of gestation until the equivalent of day 3 after birth of culture (see also Fig. 1). The sum of PFC determined at the different days is given as total PFC response.

I thank Ms Deborah Norman for technical assistance.

Augmentation by interferon of human natural and antibody-dependent cell-mediated cytotoxicity

LYMPHOCYTES from normal individuals may have considerable levels of cytotoxic reactivity against tumour cells, mediated by NK (natural killer) cells[1]. There are many similarities between NK cells and the effector cells (K cells) mediating antibody-dependent cell-mediated cytotoxicity (ADCC) against tumour target cells[2,3], and they may in fact be identical cells. *In vivo* inoculation of rodents with viruses[4,5], immunostimulants[4,6–8], tumour cells[4] and other interferon inducers[8] results in augmented NK activity. Interferon (IF) was shown to have a major role in rapidly boosting mouse NK activity, both *in vivo*[9,10] and *in vitro*[9]. Trinchieri and Santoli[11] have suggested that IF could also augment human NK activity. However, the preparations used might have contained a variety of other lymphokines. The present study shows that IF can indeed augment human NK activity and also ADCC.

Peripheral blood mononuclear leukocytes (PBL) were collected from normal adult donors by centrifugation of heparinised blood on Ficoll–Hypaque gradients. Cytotoxicity was measured in a 4-h ^{51}Cr-release assay, with K562 used as the target cell for NK, and Chang liver cells coated with rabbit IgG antibody as the target for ADCC[2]. All experiments were carried out with several effector : target cell ratios, and activity was expressed in lytic units (LU) per 10^7 cells, 1 LU being defined as the number of cells required to produce 30% specific cytotoxicity[2]. Three different, partially purified, human IF preparations were used: lymphoblastoid IF (IF_{LB}), induced by Sendai virus (batch LNI/77/3A; 1.57×10^6 U IF per mg protein); leukocyte IF (IF_{LE}), induced in human leukocytes by Sendai virus[12] (lot 1, 1.1×10^6 U per mg protein); and fibroblast IF (IF_F), induced by poly I : C (3×10^5 U IF per mg protein).

Two rabbit antibodies against human IF were used: anti IF_F (pool 29–33, anti-IF titre of 10^3 per ml) and anti-IF_{LE} (ref. 13) (R24, titre of 10^4 per ml). To evaluate the effects of the IF preparations, PBL ($2–5 \times 10^6$ per ml) were preincubated at 37 °C with IF (usually 10^3–10^4 U ml^{-1}) and then washed before

Table 1 Effect of various human interferon preparations on cytotoxic activity of peripheral blood mononuclear cells

Expt 1, preincubation of PBL at 37 °C for 18 h; expt 2, preincubation of PBL from another donor at 37 °C for 1 h.

testing for cytotoxicity. To evaluate the effects of anti-IF, various dilutions of antisera were added to the preincubation mixtures.

With some donors, augmentation in NK by IF was seen within a few minutes, with a peak at about 1 h (for example donor 2, Table 1). The three IF preparations gave parallel results, each showing effects down to 10 U ml^{-1} or less. Table 2 summarises our overall results with several normal donors. NK activity of some donors was boosted strongly, as much as 16-fold, whereas that of others was unaffected. The NK activity of a similar proportion of donors was appreciably (>150% of control LU per 10^7 cells) boosted at 1 h and 18–20 h. In contrast, boosting of K-cell activity occurred more frequently after overnight incubation. The variations in responsiveness of different donors may be analogous to experiments in mice[9], in which sensitivity to IF varied among strains and was influenced by previous *in vivo* exposure to activating stimuli. Our data on NK activity agree fairly well with those of Trinchieri and Santoli[11], but it is not clear why they failed to detect the boosting of K-cell activity, as they preincubated their cells for 18 h.

To obtain further support for the role of IF as the active molecule in augmentation of human NK- and K-cell activities, we tested whether antibodies to IF could block the effects of IF. IF_{LB} was used for these experiments, so as to have an IF preparation from a source different from those used for immunisations, making it less likely that antibodies to other contaminating proteins would be responsible for the effects. Both antisera were able to block the boosting by IF_{LB} of NK- and K-cell activities completely (Table 3). In fact, these reagents caused a decrease to below unboosted levels. This was not due to toxicity, as after removal of the reagents, the cells could still be stimulated by IF and were normally responsive to the mitogenic effects of phytohaemagglutinin. Inhibition by IF–anti-IF complexes seemed unlikely as we have never been able to detect more than 5 U of IF per ml medium after 18 h incubation of PBL. However, to control further for this possibility, we compared the effects of anti-interferon with those of anti-bovine serum albumin (BSA), which would be expected to form complexes with the albumin in the fetal bovine serum (Table 4).

Table 4 Comparison of effects of anti-interferon and anti-bovine serum albumin on augmentation of cytotoxic activity by lymphoblastoid interferon

	NK activity		ADCC activity	
Treatment (18 h at 37 °C)	Lytic units per 10^7 cells	% Of control	Lytic units per 10^7 cells	% Of control
Control	111.1	—	175	—
IF_{LB} (1,000 U)	191.6*	172	230.9*	143
IF_{LB} + anti-IF_F (1:100)	95.5	86	25.7*	15
Anti-IF_F (1:100)	28.8*	26	5.0*	3
IF_{LB} + anti-BSA (1:100)	187.1*	169	123*	70
Anti-BSA (1:100)	99.7	89	38.4*	22

* Significantly different from untreated control, $P < 0.05$

In contrast to the inhibition of NK activity and blocking by boosting by IF, the anti-BSA has no significant effects, although it did inhibit ADCC and its boosting by IF, presumably due to the known inhibitory effects of immune complexes on ADCC.

Because of the effect of complexes on ADCC and our inability to prepare $F(ab')_2$ fragments of anti-interferon (sufficient quantities of the reagents were not available), the effects of anti-interferon on boosting of ADCC by interferon cannot be readily interpreted. However, the marked effects of anti-interferon on NK activity seem to be specific and may indicate a normal role of IF in maintaining this effector cell function. As brief preincubation of IF with lymphocytes can induce activation of NK cells, it seems likely that surface-bound IF can lead to activation during the assay. The results with anti-IF suggest that some spontaneous NK activity results from activation during culture by IF bound *in vivo* or secreted during the assay.

The IF-activated effector cells had the same characteristics as NK cells. After incubation with IF for 18 h and before testing, monocytes were removed by passage of the cells over Sephadex G-10. No removal of cytotoxic activity against K562 or against antibody-coated Chang cells was observed after such treatment. Like NK and K cells[2], the IF-induced cytotoxic cells had Fc receptors for IgG, with complete removal of reactivity by adsorption on immune-complex monolayers.

The rapid and strong potentiation of cytotoxic effector cell activities by IF has important implications for *in vivo* resistance against tumour growth. These effects need to be seriously considered as possible mechanisms for the anti-tumour effects of a variety of immune adjuvants—as well as those of IF itself—which are being used in immunotherapy trials.

Human IF preparations were obtained from the NCI Interferon Working Group, and rabbit anti-IF antibodies from the Antiviral Substances Program, NIAID.

Primary sensitisation and restimulation of human lymphocytes with soluble antigen *in vitro*

RESEARCH with human lymphocytes is restricted by ethical constraints on sensitising individuals *in vivo* before *in vitro* experiments. In humans specific restimulation of proliferative responses was first shown using allogeneic lymphocytes as antigen and has since been developed into the primed lymphocyte test[1]. In a model similar to this test, again using cell-bound antigens, Newman *et al.*[2] showed sensitisation and restimulation by hapten-modified autologous cells. With soluble protein antigens and lymphocytes from donors who had been sensitised to these antigens *in vivo*, Levis and Dattner[3] showed specific restimulation of proliferative responses, after the cells had been cultured in the presence of antigen for 10 or more days. We report here that, using a similar culture method, but cells from individuals who have not been sensitised *in vivo* to the relevant protein antigens, we have been able to obtain *in vitro* sensitisation and specific restimulation, sensitisation of the lymphocytes being determined by a subsequent specific proliferative response.

Lymphocytes were isolated by standard techniques from human peripheral blood and cultured for 10 d with the sensitising antigen. Cells were then washed and restimulated by culturing them for a further 2 or 3 d in the presence of the same or different antigens. Proliferative responses were measured by the incorporation of tritiated thymidine. Antigens used were keyhole limpet haemocyanin (KLH; Calbiochem), schistosomiasis soluble egg antigen (SEA), the synthetic polypeptides (T, G)-A–L (copolymer of L-(tyrosine, glutamic acid) coupled to D,L-alanine on a poly-L-lysine backbone, batch no. MC 9) and GAT (random copolymer of 60% glutamic acid, 30% alanine and 10% tyrosine, batch no. GAT 8) (both Miles Yeda), purified protein derivative (PPD) and tetanus toxoid (both RIV). Many individuals have been knowingly sensitised to these latter two antigens; but we emphasise that all data presented here have been obtained using combinations of antigens and cells which failed to respond in a direct proliferative assay.

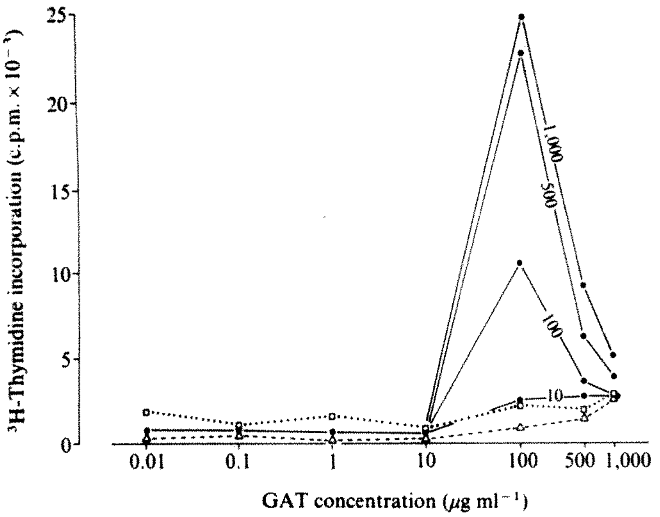

Fig. 1 Secondary responses of lymphocytes sensitised *in vitro* to GAT. Blood was obtained by venipuncture and lymphocytes were isolated by Ficoll–Hypaque density centrifugation (1.077 mg ml^{-1}). Cells from the interphase were washed 3 times in Hank's balanced salt solution and resuspended in RPMI 1640 supplemented with 30% AB serum, 100 U ml^{-1} penicillin and 100 μg ml^{-1} streptomycin, and adjusted to 2×10^6 cells per ml. Of this cell suspension, 2.5 ml was mixed with 2.5 ml of the antigen diluted in RPMI 1640 (without serum) in a 25-cm bottle (Falcon no. 3013). Bottles were gassed with a 5% CO_2/air mixture, closed and cultured for 10 d at 37 °C in upright position. Approximately 1 in 10 of the cultures failed to retain an adequate *p*H and were discarded. Cells were then collected, adherent cells with a rubber policeman, washed once, and readjusted to 2×10^6 cells per ml in RPMI 1640 with 30% AB serum. Restimulation was carried out in duplicate or triplicate in flat-bottomed microtitre plates. A volume of 0.1 ml of the cell suspension was mixed with 0.1 ml RPMI 1640 (without serum) containing antigen. After 48 h tritiated thymidine was added, the cultures were collected 18 h later, and samples counted in a liquid scintillation counter. Seven different sensitising concentrations of GAT are shown on the abscissa. The second cultures of the sensitised lymphocytes were restimulated with: 10, 100, 500 or 1,000 μg ml^{-1} of GAT (●), 100 μg ml^{-1} of PPD (□), or medium only (△). When 10 μg ml^{-1} or less of GAT was used in the sensitising culture, all responses to GAT in the second culture were less than 1,000 c.p.m. and are not shown separately. The secondary responses of the GAT-sensitised lymphocytes to (T, G)-A--L in the concentrations 10, 100, 500 and 1,000 μg ml^{-1} are also not shown. These responses were all in the range of the responses to PPD (with a maximum of 3,200 c.p.m.). In this experiment there was no evidence for cross-reactivity between GAT and (T, G)-A--L.

To obtain *in vitro* sensitisation, we found that the most critical parameter was the concentration of antigen during the first culture. Figure 1 shows an example of results obtained, in which GAT was used as antigen. With sub-optimal low concentrations of antigen no specific proliferative response was found in the second culture. In this experiment, 100 μg ml^{-1} GAT yielded optimal specific sensitisation, as shown by the highly significant response in the second culture to GAT compared with that to other antigens. Higher concentrations showed low, or even depressed, proliferative responses in the second culture, depending on the antigen used. In general, the background proliferative responses, that is, the responses to unrelated or no antigen in the second culture, increased with concentrations of antigen slightly higher than the optimal concentration in the first culture. The nature of this phenomenon is now being investigated. Finally, the concentration of antigen used in the second culture had to be varied but was less critical. The optimal concentration of antigen for the second culture has always been greater than the optimal sensitising concentration (Figs 1, 2). For sensitising cultures with PPD and tetanus toxoid, the optimal antigen concentrations were less than 1/10th of the optimal concentrations routinely used by us for the direct lymphocyte transformation test with *in vivo* sensitised cells.

Figure 2 gives the results of an experiment in which cells were separately sensitised to three different antigens and restimulated with each of the three antigens. The data used were obtained with the optimal concentrations of each antigen. For all three antigens the proliferative response was significantly increased ($P < 0.01$, by analysis of variance on log transformed data) if the same antigen was used in the first as well as in the second culture. The lymphocytes in this and similar experiments were all negative in the direct lymphocyte transformation test with these antigens. Only the absence of current immunity can be concluded from a negative direct lymphocyte transformation test, and especially for tetanus toxoid a negative direct test does not exclude prior *in vivo* sensitisation. In further experiments, we used other antigens including synthetic polypeptides, for which it is much less likely that individuals have been sensitised *in vivo*. Table 1 shows the results of such experiments. In each experiment, at least two different antigens were used at several concentrations in the sensitising cultures. The lymphocytes from each culture were then restimulated with the relevant antigens. It was again shown that a specific proliferative response was only obtained using the same antigen in the second culture as had been used in the sensitising culture. Each experiment has been repeated at least three times with different donors and demonstrates our ability to sensitise unprimed human lymphocytes *in vitro* to different protein antigens.

We thus find that we can consistently sensitise lymphocytes from many different individuals to the antigens KLH, GAT, PPD and tetanus toxoid. Of 14 individuals tested with (T, G)-A--L and GAT, all responded to GAT whereas three failed to respond to (T, G)-A--L. These three also failed to show cross-sensitisation by GAT for response to (T, G)-A--L in the second culture, whereas 9 out of the other 11 showed such a reaction. For one of the non-responders the test has been repeated three times with different bleedings showing the same results. The genetic basis of this unresponsiveness to (T, G)-A--L is not known but is now under investigation. Restimulation after

Table 1 Proliferative response of human lymphocytes to restimulation *in vitro*

Antigen concentration (μg ml^{-1})		
First culture	Second culture	Response in c.p.m. per 10^5 cells ± s.d.
KLH 1	KLH 100	*41,163 ± 823

	GAT 1,000	*51,376 ± 2,055
	—	14,128 ± 2,684

Lymphocytes from one donor were cultured with different antigens in the first culture and restimulated as indicated. The results show the mean and standard deviation of duplicates. In this particular experiment, cross-reactivity between (T, G)-A--L and GAT which was found in nine out of eleven cases, is also shown. Each experiment was repeated at least three times with different donors and showed the same pattern of results.

* Results significantly different from controls ($P < 0.01$).

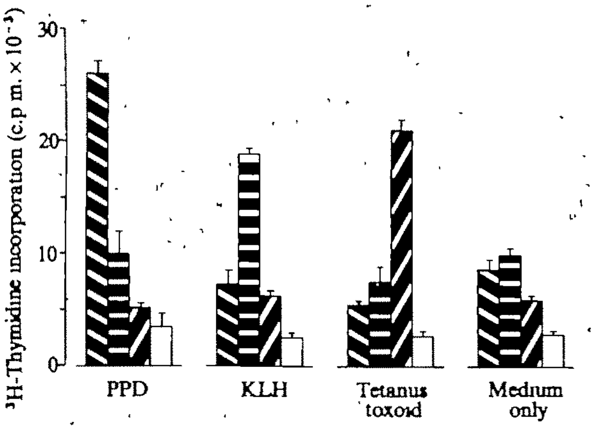

Fig. 2 Secondary responses of lymphocytes sensitised *in vitro* to PPD, KLH and tetanus toxoid. Lymphocytes were sensitised to four different concentrations of the antigens. Only data from the optimal sensitising concentrations are shown. These were 0 2 μg ml^{-1} of PPD (▧), 0 2 μg ml^{-1} of KLH (▤), 10^{-4} Lf ml^{-1} of tetanus toxoid (▨) and medium alone (☐) The optimal concentrations of antigen for restimulation were 50 μg ml^{-1} of PPD; 100 μg ml^{-1} of KLH or 10^{-1} Lf ml^{-1} of tetanus toxoid. In this experiment, the background proliferation in the second cultures was not influenced by the concentration of the irrelevant antigens. Second cultures were carried out in duplicate and results are shown ± s d. Antigens used for restimulation are indicated on the abscissa. Antigens used for sensitisation are shown by the hatching of the bars.

sensitisation with SEA was not specific in 50% of the cases, possibly because this material is a complex of many antigens. It should be added that this culture method can also be used for sensitisation to insoluble antigens, and a study of the *in vitro* response to TNP-modified autologous cells is under way.

In vitro sensitisation to soluble antigens has been previously described by Thomas and Shevach[4] using guinea pig cells. However, in their cultures, macrophages obtained from oil-induced peritoneal exudate cells were present. Comparable culture conditions for human cells would be difficult to obtain. An alternative assay for *in vitro* sensitisation, a primary *in vitro* antibody response, should be mentioned here. This method was described in humans by Dosch and Gelfund[5], and elaborated to a further extent by UytdeHaag *et al.*[6]. Comparison of the two methods is difficult because lymphocyte proliferation has not been reported in their investigations, and we have not determined whether our cultures contain antibody-secreting cells.

Therefore, our data demonstrate that specific proliferative responses to soluble protein antigens can be induced *in vitro* using peripheral blood lymphocytes from donors who had not been immunised *in vivo* against these antigens. It is hoped that this assay will lead to a further understanding of the control of the immune response in man, and in particular the analysis of human immune response genes.

This work was supported by the Koningin Wilhemina Fonds and the J. A. Cohen Institute for Radiotherapy and Radiation Protection (IRS). SEA was obtained from Dr Deelder.

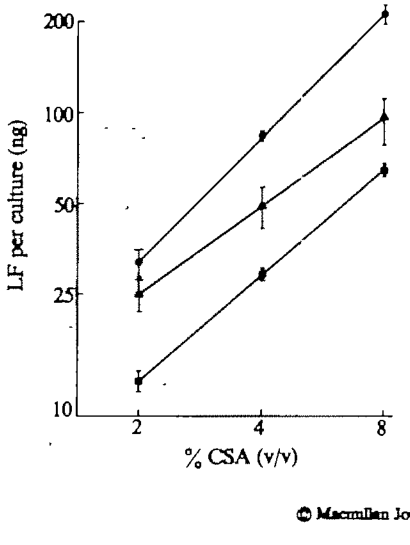
Immunochemical quantification of *in vitro* neutrophilic granulocyte differentiation

IN the presence of colony stimulating activity (CSA)[1-5], both normal and neoplastic cells of the neutrophilic granulocyte (neutrophil) and monocyte–macrophage cell series proliferate and differentiate in semi-solid and liquid cultures[6-9]. However, as conventionally performed, the clonal assay for CSA depends on cellular proliferation, and does not provide quantitative information on the role of CSA in differentiation. Lactoferrin (LF) is a specific protein marker for the neutrophil cell series[10-12], and among bone marrow cells is found exclusively in the specific granules of the maturing neutrophil[13,14]. These granules first appear at the myelocyte stage of cytodifferentiation[15]. Thus, synthesis of LF is a biochemical event which may be used to quantify a specific state of neutrophil differentiation. We previously reported the purification of murine LF[16], and its quantification by radioimmunoassay[17], and also the development of a slide chamber method for culturing bone marrow cells in liquid medium[18]. We now report that in similar cultures, the net synthesis of LF is correlated in a dose-dependent manner with CSA concentration. To our knowledge, this is the first demonstration of a quantitative relationship at both the biochemical and cellular levels between CSA and a specific marker of neutrophilic granulocyte differentiation[19].

Fig. 1 Dose–response relationship between the net synthesis of lactoferrin and the concentration of CSA in cultures of mouse bone marrow cells. Cells were obtained from 4-month-old male BALB/c mice from our breeding colony A single cell suspension in Hank's balanced salt solution deficient in calcium and magnesium was layered over a solution of Ficoll–Hypaque (density 1.077 g cm^{-3}), and centrifuged at room temperature for 30 min at 400 g. Cells collecting at the interface were resuspended in RPMI-1640 culture medium containing 20% fetal bovine serum, and used to initiate cultures (1 ml, 1.25 × 10^4 cells) in four-chamber Lab-Tek microscope slide chambers[18]. Cultures were stimulated at time zero by the addition of various amounts of CSA from endotoxin-treated mouse lung[20], and were incubated at 37 °C in a fully humidified atmosphere containing 7.5% CO_2. Cultures were terminated at various times by carefully drawing off the medium and adding 0.5 ml of 0.01 M phosphate buffered saline, *p*H 7.4, containing 0.1% Triton X-100 and 0.3 M sodium chloride. The mixture was allowed to stand for 20 min at 4 °C after which it was removed by aspiration. Aliquots of the aspirate were taken for quantification of LF by radioimmunoassay[17]. With the low initial cell inoculum used in these particular experiments (where correlation with microscopic observations was important) levels of LF on days 1 and 2 of culture were not sufficiently high to be detected by the radioimmunoassay. Each point is the mean of two to three replicates. The vertical bars indicate the range of values on day 3 (■), day 4 (▲), and day 5 (●).



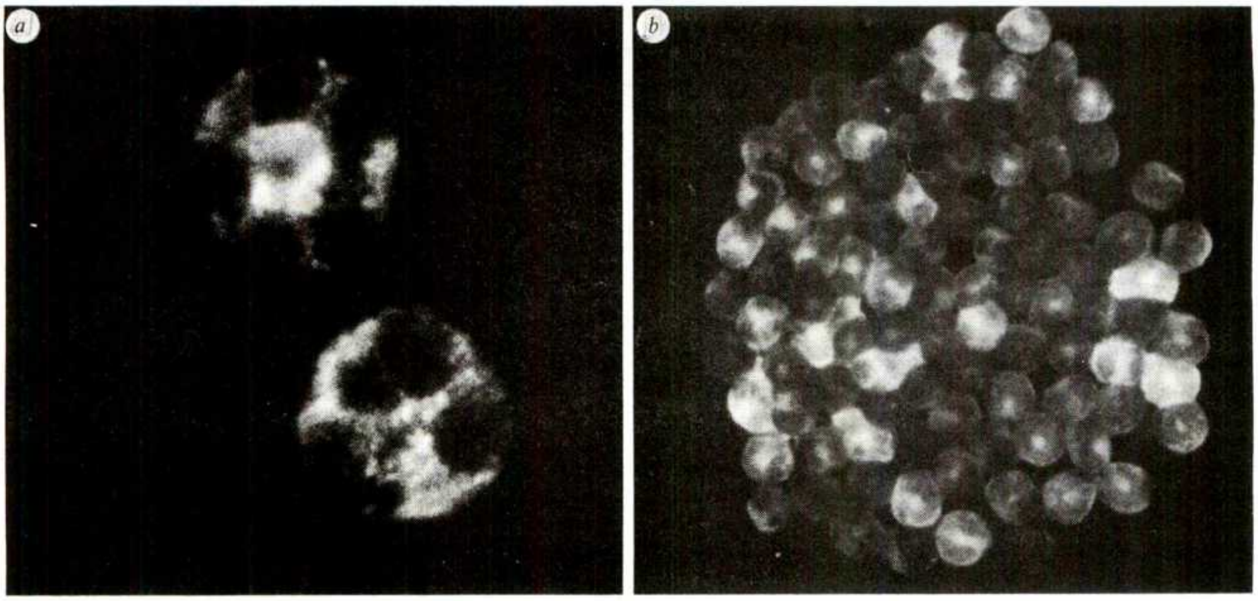


Fig. 2 Immunocytofluorescence of LF-containing, cultured murine bone marrow cells. After careful removal of the culture medium, wet slides were immediately centrifuged in a cytocentrifuge and cells were fixed in absolute ethanol containing 10% formalin[18]. Fixed cells were incubated with the fluorescein-labelled F(ab')$_2$ fragment of rabbit IgG raised against murine LF[16]. Slides were viewed using a Leitz Orthoplan fluorescence microscope equipped with a 100-W mercury lamp and epi-illumination. Photographs were taken with a Leitz Orthomat camera and Kodak Ectachrome ET135 film. *a*, Mature neutrophils showing a pattern of fluorescence characteristic of cells which have differentiated to the myelocyte stage or beyond (×1600); *b*, a single neutrophilic granulocyte clone displaying asynchronous differentiation as indicated by the presence of both LF-positive and LF-negative cells (×400).

Slide chamber cultures of murine bone marrow cells were stimulated by the addition of CSA from endotoxin-treated mouse lung[20]. When examined between days 3 and 5, a linear dose–response relationship was observed between dose of CSA and the total amount of LF per culture (Fig. 1). In addition, it was evident from these data that the magnitude of the response between day 3 and day 5 increased approximately threefold as CSA concentration increased from 4 to 8%.

It was possible to extend these biochemical observations to the cellular level by examining cultured cells which had been fixed and exposed to a fluorescein-conjugated anti-LF antibody. LF-containing cells displayed a characteristic granular pattern of fluorescence (Fig. 2*a*). As shown in Table 1, there was a linear dose–response relationship between dose of CSA, the number of LF-containing cells, and the total number of cells per culture. The latter response (total cells) was more pronounced because the marrow cell population contained precursor cells which proliferated in response to CSA, but whose progeny did not contain LF (neutrophils less mature than myelocytes, and all cells of the monocyte–macrophage series).

The distinctive growth pattern of neutrophils offered an additional advantage for immunocytofluorescence studies. In the liquid cultures, clones of neutrophils grew as discrete, tight, spheroidal cell groupings which could be easily identified through the first 3 days of culture. In these early cultures, we observed that within individual clones, the proportion of cells which contained LF varied from zero to unity, with some clones consisting of both LF positive and LF negative cells (Fig. 2*b*). This pattern of asynchronous differentiation within individual clones has also been observed in both normal and leukemic *in vitro* erythropoiesis[21,22]. Note that with the cell concentrations used in the present experiments, cell crowding made interpretation of clonally-related events difficult beyond day 3 of culture. However, use of a lower initial cell inoculum (5 to 10×10^2 cells) resulted in sufficient spatial separation of individual clones to permit observation of clonally-related events beyond day 3. In these conditions, we observed that as tight clones matured, all cells eventually contained LF[23]. We are currently investigating the effects of CSA concentration on the time course of LF synthesis in these clones composed exclusively of cells committed to neutrophilic granulopoiesis.

Table 1 Effect of increasing concentration of CSA on the total number of LF-containing cells and on the total number of cells per culture

CSA concentration (μl per ml culture)	No. of cells* LF-containing	Total
4	1,326 ± 99	3,384 ± 261
16	2,347 ± 153	5,756 ± 206
64	3,188 ± 301	8,856 ± 643

* Details of the culture and immunofluorescence procedures are as described in the legends to Figs 1 and 2 except the initial cell inoculum was 1×10^4 cells (8% of the cells contained LF). In addition to cells committed to neutrophilic granulopoiesis, the total cell population contained cells of the monocyte–macrophage series which also proliferated in response to CSA. Cultures were terminated after 3 days, and all cells in each culture chamber were counted and classified by sequential observation with phase contrast and fluorescence microscopy (×400). Each point is the mean ± s.e.m. of four chambers.

There is now good evidence that CSA preparations are heterogeneous with respect to biological activity, and that different species of CSA may govern the differentiation of neutrophilic granulocytes as distinct from monocytes and macrophages[24–27]. Furthermore, there is the possibility that some molecules of CSA might have either proliferative- or differentiative-associated functions while others might possess both of these activities. The assays for LF presented above should aid in the identification and purification of such postulated CSA species. Finally, the question as to whether CSA plays a direct part in neutrophil differentiation must remain open. The demonstration of a dose–response between CSA and net synthesis of a differentiation-associated protein such as LF is necessary but not sufficient proof of direct involvement, as the response might be secondary to an earlier, primary effect on neutrophil proliferation. However, studies on CSA-dependent synthesis of LF in the presence of appropriate inhibitors of DNA and RNA synthesis should provide further insight into this question.

In conclusion, we anticipate that the radioimmunoassay and immunocytofluorescent procedures for the detection and quantification of LF described here, both individually and in combination, will prove useful in further defining the mechanism of action of CSA in the regulation of *in vitro* granulopoiesis.

5,6-Epoxyretinoic acid opposes the effects of 12–*O*-tetradecanoylphorbol-13-acetate in bovine lymphocytes

12-*O*-TETRADECANOYLPHORBOL-13-ACETATE (TPA), the most potent of a series of tumour-promoting agents isolated from croton oil[1], has been found to be highly active in bovine lymphocytes as a stimulator of choline phospholipid metabolism[2], an inducer of ornithine decarboxylase[3], and a co-mitogen when used in conjunction with phytohaemagglutinin (PHA)[4,5]. These effects of TPA in the bovine lymphocyte system are antagonised by retinoic acid[2,5], an agent which opposes the tumour-promoting action of phorbol esters in mouse skin[6,7] and inhibits chemical carcinogenesis in several other tissues[8]. However, the dose–response curves for retinoic acid in inhibiting these effects in lymphocytes are broad and extend over several orders of magnitude, suggesting that retinoic acid may have to be metabolised to be biologically effective in this system.

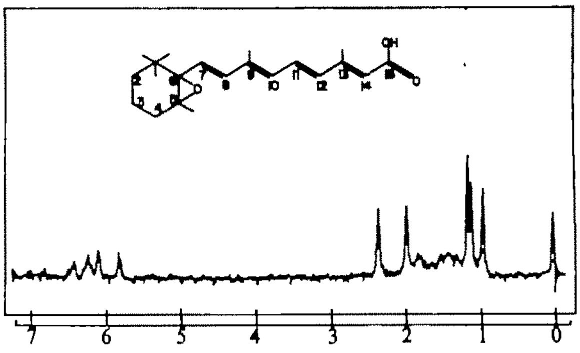

Fig. 1 The 60 MHz proton magnetic resonance spectrum of 5,6-epoxyretinoic acid. $DCCl_3$ containing 1% tetramethylsilane as internal standard was the solvent used in recording the above spectrum: δ (p p.m.) 5.77–7.08 (6H, m, olefinic protons on side chain); 2.33 (3H, s, H_3C- on C-9); 1.97 (3H, s, H_3C- on C-13); 1.2–1.9 (6H, m, $-CH_2-$ in ring); 1.13, 1.08 (6H, 2s, H_3C- on C-1); 0.92 (3H, s, H_3C- on C-5). This spectrum agrees with data presented by Vetter *et al.*[11] and is very similar to the spectrum reported for 5,6-epoxyretinal (ref. 12). The mass spectrum of 5,6-epoxyretinoic acid (melting point 153–154 °C) contained an intense molecular ion (M, *m/e* = 316) and M+1 and M+2 peaks with intensities of 21% M and 2% M, respectively. No ions of higher *m/e* were observed. The UV absorption maximum found for this material (337 nm, ethanol) agrees with that reported for enzymatically produced 5,6-epoxyretinoic acid (337 nm, light petroleum)[13].

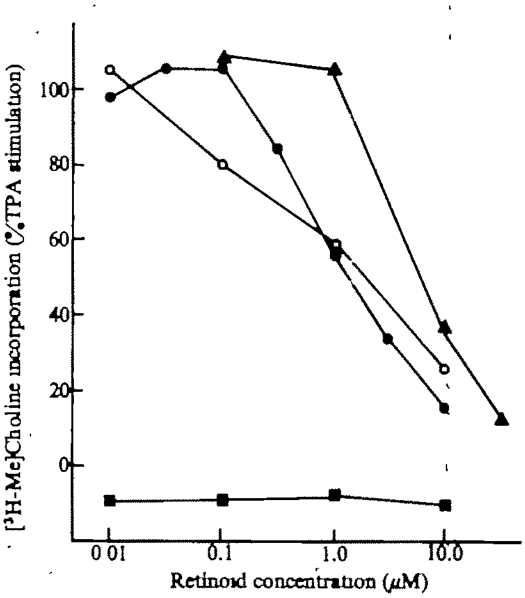

Fig. 2 Dose–response curve for the inhibition of [^{3}H-Me]choline incorporation into the phospholipids of bovine lymphocytes. Lymphocytes were prepared from bovine retropharyngeal lymph nodes as described previously[4], and were cultured in Eagle's HeLa medium supplemented with 10% bovine serum (BEHM) at a concentration of 5–10 × 10^6 cells ml^{-1} for 1 d before use. Cells were collected by centrifugation at 150*g* for 10 min and resuspended in Dulbecco's phosphate-buffered saline containing 5.6 mM glucose at 3 × 10^6 cells ml^{-1}. Five-ml portions of cell suspension were then planted in 12-ml conical centrifuge tubes containing retinoic acid or the epoxide; after 15 min at 37 °C, 2 μCi of [^{3}H-Me]choline (69.5 Ci $mmol^{-1}$) and 50 pmol of TPA were added to each culture. Dimethyl sulphoxide, used as the solvent for TPA and the retinoids, was present at a final concentration of 0.55% (v/v) in all cases. After a 1-h incorporation period, the cells were collected and the phospholipids extracted and purified as described elsewhere[2] Radioactivity in the dried phospholipid extracts was quantitated by liquid scintillation spectrometry. Points represent the means of duplicates. ○, TPA plus retinoic acid; ●, TPA plus 5,6-epoxyretinoic acid; ▲, TPA plus 5,6-epoxyretinoic acid with medium containing 10% bovine serum; ■, 5,6-epoxyretinoic acid without TPA.

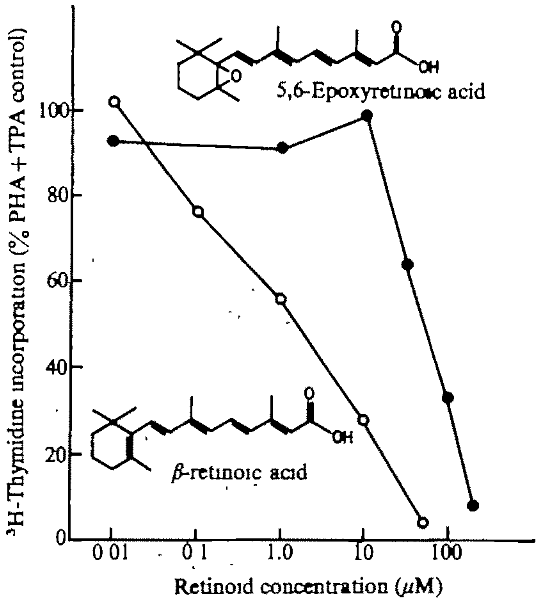

Fig. 3 Dose-response curves for the inhibition of lymphocyte mitogenesis by retinoic acid (○) and 5,6-epoxyretinoic acid (●). Cells were cultured for 1 d as described in the legend to Fig 2. The lymphocyte cell density was then adjusted to 3×10^6 cells ml^{-1} in BEHM and 5-ml aliquots of the suspension were planted in conical 12-ml centrifuge tubes. PHA-P, used at a final dilution of 1:10,000, TPA (10 nM) and the retinoids were added to cultures concurrently. The cultures were gassed with 5% CO$_2$ in air and incubated at 37 °C on a slant for 48 h The cells were then pulse-labelled for 2 h with 2 μCi per culture of ^{3}H-thymidine (64.7 Ci mmol^{-1}). The incorporated radioactivity was assayed using a standard Whatman GF/C filter disk procedure[15]. Points represent the means of triplicate cultures

The possibility that epoxidation might be involved in the activation of retinoic acid and related retinoids was suggested by two observations. First, 10,11-epoxymethylfarnesoate (insect juvenile hormone III), which bears the epoxide moiety at a position corresponding to the double bond in the ionone ring of retinoic acid, was found to oppose the actions of TPA in bovine lymphocytes and exhibited a much steeper dose-response curve[9]. Second, we have demonstrated that epoxidation at the 5,6-position of β-ionone strikingly increases its activity as an antagonist of the co-mitogenic action of TPA as well as the TPA stimulation of phospholipid metabolism[10]. We describe here the chemical synthesis and biological testing of the 5,6-epoxy derivative of retinoic acid as an antagonist of TPA action in bovine lymphocytes. We report that the introduction of an epoxide group at this position results in an enhanced ability to oppose certain effects of TPA in these cells.

Retinoic acid (2 mmol) was epoxidated by treatment with a 10-fold molar excess of monoperphthalic acid in ethyl ether (30 ml) at room temperature, and the reaction was monitored by thin layer chromatography on silica gel, with 20% ethanol in light petroleum (boiling point 40–60 °C) as the eluant. Within 0.5 h, all the retinoic acid had been consumed, with the formation of a single more polar product, as shown by thin layer chromatography. This reaction mixture was extracted twice with two volumes of aqueous NaHCO$_3$ (2% w/v) and washed with two volumes of water. When the organic phase was taken to dryness under vacuum, the product crystallised spontaneously (1.7 mmol); the latter was recrystallised from ethyl ether/light petroleum and characterised as 5,6-epoxyretinoic acid. The structure verification of racemic 5,6-epoxyretinoic acid is presented in Fig. 1.

As noted above, TPA accelerates the incorporation of choline into the phospholipids of bovine lymphocytes, and this response is antagonised by retinoic acid[2]. Figure 2 shows that 5,6-epoxyretinoic acid is also an active antagonist of this process and that when an effective concentration has been reached it exhibits a steeper dose-response curve than retinoic acid. Although other explanations of the data are possible, this observation is consistent with the hypothesis that epoxidation of the 5,6-double bond may be involved in the metabolic activation of retinoic acid. This possibility is strengthened by the report by Napoli *et al.*[14] that 5,6-epoxyretinoic acid is a major retinoic acid metabolite in the intestinal mucosa of the rat.

Several additional points should be made concerning the data presented in Fig. 2. First, it seems unlikely that the inhibitory action of the epoxide is merely a manifestation of toxicity, as it does not affect the basal level of [^{3}H-Me]choline incorporation, and second, when 10% serum was included in the incubation medium the effective inhibitory range of epoxide concentrations was shifted upward by an order of magnitude. This observation suggests that serum and certain cellular components may sequester or facilitate the inactivation of low levels of 5,6-epoxyretinoic acid and thus account for the shoulder on the dose-response curve. This same situation was encountered in earlier experiments in which a similar serum effect on the effective inhibitory concentrations of 5,6-epoxy-β-ionone was observed[10].

In Fig. 3, the contrast of broad- compared with steep-sloped dose-effectiveness curves for retinoic acid and the epoxide is clearly shown in the inhibition of the mitogenic response. As reported previously, retinoic acid inhibits TPA-mediated co-mitogenesis over a broad range of concentrations[5]; however, it

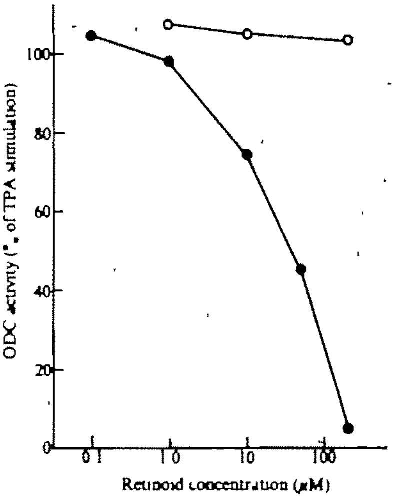

Fig. 4 Dose-response curves for the inhibition of ornithine decarboxylase (ODC) induction by retinoic acid (○) and 5,6-epoxyretinoic acid (●). Lymphocyte cultures were planted as described in the legend to Fig. 3. Eighteen hours after the concurrent addition of PHA, TPA, and retinoids to the cultures, the cells were collected and washed twice with cold 0.9% NaCl. The lymphocytes were then suspended in 0.3 ml of 50 mM sodium phosphate buffer (*p*H 7.2) containing 0.1 mM EDTA, and disrupted by four cycles of freezing and thawing. After centrifugation of the disrupted cells at 2,000*g* for 15 min, a clear supernatant was obtained. Ornithine decarboxylase activity in this supernatant was assayed by measuring the release of ^{14}CO$_2$ from DL-[1-^{14}C]ornithine hydrochloride (49.9 mCi mmol^{-1}). The assay mixture contained 35 mM sodium phosphate (*p*H 7.2), 0.2 mM pyridoxal phosphate, 4 mM dithiothreitol, 1 mM EDTA, 0.4 mM L-ornithine containing 0.5 μCi of DL-[1-^{14}C]ornithine hydrochloride, and 100 μl of lymphocyte supernatant in a total volume of 0.25 ml. Incubation of the assay mixture at 37 °C was carried out in 15-ml corex tubes equipped with centre well assemblies and capped with serum stoppers After 1 h, the reaction was stopped by the addition of 0.5 ml of 2 M citric acid, however, incubation was continued for one more hour to ensure complete absorption of ^{14}CO$_2$ by the ethanolamine and methoxyethanol (0.2 ml; 2:1) in the centre well. Finally, the contents of the centre well were transferred to a vial containing 10 ml of toluene-based scintillation fluid and 2 ml ethanol. Radioactivity was measured by liquid scintillation spectrometry. Points represent the means of triplicate cultures.

can be seen that retinoic acid epoxide displays a steep dose–response curve, as anticipated for the active inhibitory species. The fact that higher concentrations of the epoxide, as compared with the parent compound, are required to achieve inhibition is thought to reflect the above noted difficulty in delivering the chemically reactive epoxide to the appropriate cellular sites rather than an inherently lower activity of this derivative. Again, toxicity does not seem to be the basis of this inhibitory action of 5,6-epoxyretinoic acid, for 48 h of exposure to this agent does not affect the lymphocyte viability, as measured by the trypan blue exclusion test.

In a third series of studies, we have tested the ability of 5,6-epoxyretinoic acid to inhibit the induction of ornithine decarboxylase by TPA. Ornithine decarboxylase, the rate-limiting enzyme in polyamine biosynthesis, is among the earliest and most thoroughly studied responses induced by the application of TPA to mouse skin[16]. The TPA induction of this enzyme, which is prevented by retinoic acid, has provided a useful test system for assessing several retinoid analogues as biological antagonists of TPA in mouse skin. In PHA-treated lymphocytes, retinoic acid also blocks the TPA-induced ornithine decarboxylase activity; however, it must be added to cell cultures before TPA to exert this effect[3]. This temporal dependency is reflected in Fig. 4, in which the induction of ornithine decarboxylase by TPA proceeds unhindered by concurrently added retinoic acid. However, in these same conditions, 5,6-epoxyretinoic acid is a highly effective inhibitor of ornithine decarboxylase induction (Fig. 4).

The present results do not prove the concept of metabolic activation of retinoic acid, but they are consistent with the suggestion that an activation process may involve epoxidation at the 5,6-position. At the very minimum, it can be stated that epoxidation of retinoic acid at the 5,6-position is a tolerated modification of retinoic acid for activity of this agent as an antagonist of certain effects of TPA in the bovine lymphocyte system.

Thus, although bovine lymphocytes have not been used in tumour-promoting studies with phorbol esters or in anti-tumourigenic studies with retinoids, the present results and our earlier findings[2–5,9,10] clearly demonstrate that they are a good indicator system for studying the modulation of metabolic processes by these two classes of agents. The responsiveness, the ready availability of the cells, and the ease of staging prompts their further use in studies of the molecular mechanisms by which these agents act.

Migrating epidermis produces AB$_2$ collagen and requires continual collagen synthesis for movement

EPITHELIAL CELLS demonstrate remarkable motility during the *in vivo* processes of wound healing, organogenesis and neoplastic invasion[1]. We have been interested in the control of epithelial motility. From earlier studies we know that *in vitro* epithelial movement requires the continual presence of a serum component[2,3] and a proper substratum[4]. In culturing dissociated epithelial cells, collagen-coated dishes have been found to provide a better substratum than non-coated surfaces[5]. As studies in other laboratories had suggested that epithelium produces collagen[6–8], it seemed appropriate to investigate the role of collagen in epithelial movement. Reported here are morphological and metabolic studies of a well defined tissue culture system of skin explants involving both epithelial outgrowth and epiboly. The observations support the possibility that the continual synthesis of collagen is necessary for epithelial cell movement.

The *in vitro* system we have used in measuring epithelial movement has been described elsewhere in detail[2,3]. Briefly, measured mouse skin explants are laid on plastic Petri dishes (outgrowth) and covered with medium (Dulbecco's modified Eagle's medium, DME; Gibco) plus human serum (5 mg ml^{-1}) or suspended in the medium (epiboly). At intervals, the maximal radial outgrowth or the extent of epiboly are measured. In earlier experiments we established that epithelial spread is virtually independent of DNA synthesis and thus cell division; the outgrowth measured is therefore apparently due predominantly to epithelial cell motility. Although the explant contains dermal elements the outgrowth is essentially, if not completely, epithelial, as demonstrated earlier[2,3].

Our initial questions were: does migrating epithelium of the outgrowth and epiboly systems contain collagen? If so, what types of collagen are present in the migrating epidermis? Using affinity-purified antibodies to collagen (I, III, IV and AB$_2$) and an indirect immunofluorescence (IF) assay, we found that both stationary and migrating epidermis contain type AB$_2$ collagen (Fig. 1i, 1j). Types I (Fig. 1c, 1d) and III (Fig. 1e, 1f) are found exclusively in the dermal portion of the outgrowth. Type IV (Fig. 1g, 1h) is localised to the junction of the dermis and the stationary epidermis, but not beneath the migrating epidermis.

If both migrating and stationary epidermis synthesise AB$_2$ collagen, as the IF studies suggest, proline incorporation into these cells should be demonstrable, as proline and hydroxyproline constitute 20% of the amino acid residues of AB$_2$ collagen[9]. The autoradiography of ^{3}H-proline-pulsed explants (Fig. 1a, 1b) shows silver grains over the cytoplasm of the migrating and stationary epidermis of both the outgrowth and the epiboly assays. Proline incorporation was present diffusely over the epithelial cell cytoplasm and grain density was not greater at the growing tip or the basement membrane regions. As essentially no proline incorporation was present in the dermis at any time throughout the experiment, we assume that proline is incorporated by the epithelium and not transferred to the epithelium from the dermis.

The synthesis of collagen by the epithelium was tested first by hydroxyproline synthesis and incorporation (a product of

Table 1 Epithelial spreading in the presence of the proline analogue L-azetidine-2-carboxylic acid

Experimental conditions	Linear outgrowth at 3 d (μm)	% Of control	Epiboly (%)
DME + HS (control)	465 ± 34 (35)	100	96 ± 4 (9)

DME + HS + LACA (100 μg ml^{-1}) + proline (200 μg ml^{-1})	254 ± 27(13)	58	89 ± 6 (8)

Outgrowth and epiboly experiments were set up as previously described[2,3]. Linear outgrowth is recorded as the maximal radial spread of epithelium measured from the explant edge. The data are recorded as the mean ± s.e.m. (no. of observations). Outgrowth in the presence of DME + HS for 3 d was used as the control in calculating the percent of outgrowth except for the recovery experiment (indicated by asterisk), where outgrowth after 2 d in DME + HS was used as the control. Epiboly is expressed as the mean per cent of the lower explant covered by epithelium ± s.e.m. (no. of observations) after 2 d of incubation. HS was prepared as previously described[2,3].

collagen biosynthesis), and second by incorporation of ^{3}H-proline into antigen precipitable by monospecific collagen antibodies. The synthesis of hydroxyproline by the epidermis was tested using epiboly explants incubated for 24 h in the conditions described in the legend to Fig. 1; however, in these experiments the ^{3}H-proline pulse was given for 24 h. The epidermis was removed from the dermis after incubating in hot water (55 °C) by the method of Marrs and Voorhees[10]. The epidermis was then hydrolysed and the hydrolysate analysed by the thin-layer chromatographic technique of Myhill and Jackson[11]. Approximately 4% of the applied counts comigrated with the hydroxyproline standard (H6002 Sigma).

To test for the incorporation of proline into collagen antigen, ^{3}H-proline-pulsed explants (grown as described in the legend to Fig. 1) were homogenised and extracted in 0.1 M acetic acid (24 h at 4 °C). The supernatant was dialysed (0.01 M acetic acid) and lyophilised. The dried collagen was suspended (0.01 M acetic acid to 100 μg ml^{-1}) and dialysed into neutral buffer (0.05 M Tris-HCl, pH 7.5, 0.15 M NaCl). To 0.2 ml of this solution, 0.1-ml aliquots of AB$_2$ collagen antibody (or normal

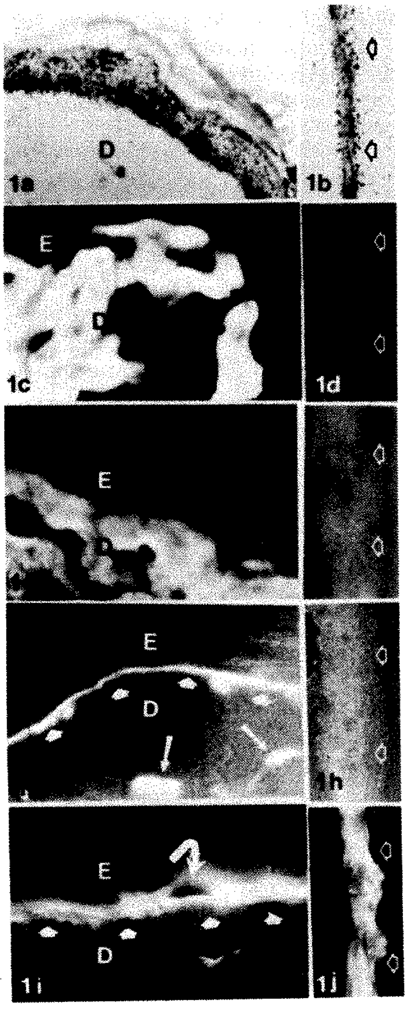

Fig. 1 Autoradiography and collagen immunofluorescence of epithelial outgrowth and epiboly. Using our previously described *in vitro* explant system[2,3], 0.2-cm disks of 6–10-week-old mouse ear skin were grown for 3 d on 0.22 μm sterile Millipore filters in DME containing 5 mg ml^{-1} dialysed and lyophilised human serum in 95% air, 5% CO$_2$ and saturated water at 37 °C. By 3 d appreciable epithelial outgrowth had extended from the explant over the filter. For the epiboly experiments, using the same tissue culture set-up, skin disks were floated on identical medium for 48 h. For both sets of experiments, at the indicated times the tissues were removed, fixed in 10% buffered formalin and prepared for light histological examination as previously described[2,3]. Autoradiography was carried out as described elsewhere[33]; the explants were pulsed for 2 h in medium containing L-[2,3^{3}H]proline (3 μCi ml^{-1}) (NEN, specific activity 20 Ci mmol^{-1}). Types I and III collagen were isolated from rat skin and types I, III and AB$_2$ collagen prepared from human placental membranes[9] by previously described methods. Type IV collagen was prepared from EHS sarcoma[36]. The collagens were judged pure by SDS-polyacrylamide gel electrophoresis of α chains (5%), CNBr peptides (7.5%) and amino acid composition. Rabbit antibodies were purified by cross-absorption on Sepharose affinity columns containing all other collagen types, followed by absorption affinity chromatography on a column containing the collagen type against which the serum was raised. They were of high titre (1 : 25,000 to 1 : 100,000) and specific for the collagen against which they were raised, as tested by haemagglutination, haemagglutination inhibition and/or radioimmunoassay[24,37–40]. Immunofluorescence (IF) staining and microscopy of frozen sections of outgrowth and epiboly tissues were done using standard techniques with fluorescein-labelled sheep anti-rabbit IgG. Immunological cross-reactivity between mouse and rat collagens (I and III) and between human and mouse collagen (AB$_2$) was demonstrated by tissue immunofluorescence and haemagglutination inhibition (type I and AB$_2$) and radioimmune assay (type III). 1a, Autoradiography of outgrowth, epithelium over dermal plug (magnification ×500); b, autoradiography of epithelial outgrowth (magnification ×500). IF using antitype I collagen antibody of skin disk (1c) (the centrally lying non-fluorescent structure is a hair follicle) (magnification ×500), and epithelial outgrowth (1d) (magnification ×500). IF using anti-type III collagen antibody of skin disk (1e) (magnification ×500) and epithelial outgrowth (1f) (magnification ×500). IF using anti-type IV collagen antibody of skin disk (1g) (magnification ×250) and epithelial outgrowth (1h) (magnification ×500). IF using anti-type AB$_2$ collagen antibody of skin disk (1i) (here the label E is above the epidermis which fluoresces at all levels) (magnification ×500), and epithelial outgrowth (1j) (magnification ×500). E, Epidermis; D, dermis; arrowheads, epithelial basement membrane; arrows, skin appendages; curved arrow, epithelial cell nucleus; open arrowheads, epithelial outgrowth. All fluorescence could be specifically inhibited by preincubation of antibody with 2.5 μg of the collagen being assayed but not by addition of other collagens.

rabbit serum) were added and the solution then incubated for 24 h (4 °C). At this time 0.2 ml of sheep anti-rabbit IgG antiserum was added followed by an additional 24 h incubation (4 °C). The AB_2 collagen antibody precipitated 15% of the acetic acid-extractable counts.

If migrating epithelium produces collagen, as the above studies suggest, is its continual synthesis necessary for epithelial movement? Inhibition studies testing this possibility are described in Table 1. No outgrowth occurred in the presence of the general protein synthesis inhibitor, cycloheximide, at concentrations of 1 and 5 μg per ml of medium. This observation agrees with the epiboly experiments of Gibbins[12]. Using the proline analogue L-azetidine-2-carboxylic acid (LACA), which affects collagen production[13,14], outgrowth and epiboly were studied. At 1 $\mu g\ ml^{-1}$ LACA, no inhibition of outgrowth was found, whereas at 10 $\mu g\ ml^{-1}$ and 100 $\mu g\ ml^{-1}$, inhibition was 90% and 100%, respectively. Removal of the inhibitor after 24 h led to the complete recovery of outgrowth. Adding L-proline to the medium (200 $\mu g\ ml^{-1}$) completely reversed the inhibition at 10 $\mu g\ ml^{-1}$ of LACA and partially corrected the inhibition at 100 $\mu g\ ml^{-1}$ LACA (Table 1). These experiments support the idea that the LACA effect is competitively inhibited by L-proline and that a proline-rich protein (perhaps collagen) is necessary for movement.

It is easiest to interpret an inhibitor experiment if the inhibition can be specifically reversed. If the proline-rich protein collagen is necessary for movement, it should theoretically be possible to observe movement in the presence of LACA if collagen were added back, that is, if collagen-coated dishes were used in the presence of LACA (Fig. 2). As observed in earlier studies[2,3] on a plastic substratum, no epithelial outgrowth is seen before 24 h, but thereafter outgrowth is linear from 1 to 3 d (Fig. 2*a*, continuous line). As seen in Fig. 2*a*, in the absence of collagen, outward spreading of epithelium abruptly stopped after the addition of LACA (100 $\mu g\ ml^{-1}$) to the medium. No outgrowth was seen if LACA was added at day 1 and no increase in outgrowth was seen if it was added at day 2. On collagen-coated dishes (Fig. 2*b*) the effect is only quantitatively different. In the absence of inhibitor and presence of collagen-coated substratum (types I, III, IV and AB_2), outgrowth at 3 d is 59% greater than that on non-coated dishes (Student's t test $P < 0.005$). If LACA was added at zero time or at 2 d, no further outgrowth occurred despite the collagen substratum. Adding the inhibitor to the outgrowth experiments after the epithelium had made contact with the substratum or to the epiboly experiments at any time caused the cessation of epithelial movement. Adding the collagen back in solution (types I, III, IV or AB_2) (50–100 $\mu g\ ml^{-1}$) did not restore motility to outgrowth or epiboly experiments in the presence of LACA.

In these studies we have demonstrated: (1) that migrating epithelium contains type AB_2 collagen but not types I, III and IV; (2) that migrating epithelium synthesises and incorporates hydroxyproline and actively incorporates proline into an antigen precipitable by antibody monospecific to type AB_2 collagen; (3) that the proline analogue LACA reversibly inhibits epithelial migration. One interpretation of these results is that migrating epithelium synthesises and contains type AB_2 collagen and that collagen production (synthesis and secretion) is necessary for movement. Although it is the simplest conclusion for these results, we do not have direct chemical evidence that collagen synthesis is necessary for movement. If only the presence of collagen in the extracellular environment were sufficient to support migration, the "add-back' experiments (collagen-coated dishes and collagen-containing media) should have overcome the LACA effect. The failure to restore motility in these experiments in the presence of LACA may indicate a more complex relationship. First, it may be possible that other proline-containing proteins are necessary for movement. We think this is unlikely not only because the cells contain collagen, but also because the system is very sensitive to inhibition (10 μg of LACA is inhibitory) and therefore the necessary proteins must be proline-rich (collagen-like). Second, it is possible that moving epithelial cells require the continual production of collagen which is cell-surface-associated or substratum-coated in a specific way which we have not been able to reproduce in the add-back experiments.

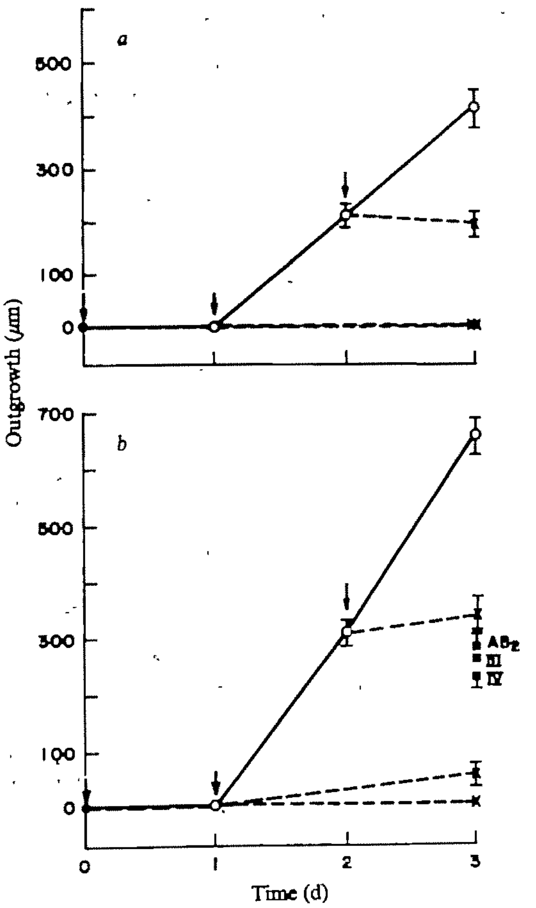

Fig. 2 Epithelial outgrowth on non-coated (*a*) and collagen-coated (*b*) dishes. As described for Fig 1 and Table 1, skin explants were laid down on Petri dishes and radial outgrowth measured over a 3-d period ○—○, DME+HS (5 $mg\ ml^{-1}$); ×---×, DME+HS (5 $mg\ ml^{-1}$)+LACA (100 $mg\ ml^{-1}$). LACA addition is indicated by arrows. Each point represents the mean of 6–14 experiments ± s.e. In *b*, the squares represent the final outgrowth after LACA (100 $\mu g\ ml^{-1}$) was added at day 2 to experiments with type III, type IV and type AB_2 collagen-coated dishes. All other points are experiments with type I-coated dishes. The dishes were prepared by the method of Karasek and Charleton[5] and the collagen concentrations were 50 $\mu g\ cm^{-2}$.

Collagen has been sought in epithelium before, although to our knowledge this is the first demonstration of type AB_2 collagen in epithelium. We were surprised that migrating epithelium did not contain type IV collagen, as epithelium is believed to produce its own basement membrane[15–20]. This observation is compatible with other studies which report that basement membrane material is not morphologically present below migrating epithelium during the initial stages of movement[15,21,22]. It is notable that AB_2 collagen has been found to be a component of some epithelial basement membranes[23,24].

LACA, a cyclic imino-acid plant extract, has been found to be competitively incorporated into proteins in place of proline[25]. Its incorporation into collagen has been demonstrated[26] and the abnormal collagens formed seem to be inadequately secreted by the synthesising cell[13,14]. The synthesis of an abnormal collagen and its inadequate secretion may explain our results in the presence of LACA. In contrast to the complete reversal by proline at low LACA concentrations (10 μg) (LACA/proline ratio of 1 : 20), only partial reversal was found at higher concentrations (100 μg) (LACA/proline ratio of 1 : 2) (Table 1). The latter case may be due to the production of abnormal collagen secondary to significant LACA incorporation[26] even in the presence of proline.

The specific role of AB_2 collagen in epithelial migration is still unknown. Other investigators have also found that collagen-coated substrata have a dramatic effect on various tissue culture systems (fibroblasts, mammary gland epithelium, hepatocytes, monocytes, corneal epithelium). The effect has included increased cellular adherence[5,27], differentiation[28,29] and protein synthesis[29]. Therefore, the observed enhancement of epithelial migration when explants are grown on collagen substrata (regardless of type) is not surprising. This phenomenon may represent a general charge or ionic effect rather than a specific property of collagen[30]. Recently, Kleinman *et al.*[31] and Murray *et al.*[32] have demonstrated in short-term cultures that dissociated epithelial cells attach preferentially to type IV collagen-coated dishes. As our studies deal with epithelial cell sheets and relatively long-term migration patterns, a meaningful comparison between these studies cannot be made.

These experiments support the hypothesis that migrating epithelium contains AB_2 collagen and must liberate this collagen for continual movement. By understanding the interaction of epithelial cells and collagen metabolism in this system, we hope to gain insight into the control of epithelial movement in particular and, perhaps, cell movement in general.

Survival and development of ciliary ganglion neurones grown alone in cell culture

NEURONAL cell death is a conspicuous part of development for many neuronal populations in the vertebrate nervous system[1,2]. Although little is known about the mechanisms that control neurone death, it seems that interactions with the postsynaptic target tissue are important. Thus, for the chick ciliary ganglion (CG), Landmesser and Pilar showed that half of the neurones present die between days 8 and 13 in the embryo. Before cell death, all the neurones extend processes to the periphery. Ablating the periphery early in development causes more than 90% of the neurones to die at the normal time[3]. We have previously shown that nearly all the neurones from chick CG, including those destined to die *in vivo*, can survive and develop in cell culture when ganglia from 8-d-old embryos are dissociated and grown with skeletal myotubes[4]. Many of the neurones innervate myotubes in these conditions. Are neuromuscular synapses necessary to prevent the death of ciliary ganglion neurones? We report here that they are not. Culture medium conditioned by contact with heart or skeletal muscle cells permits complete long-term survival of the dissociated neurones grown in the absence of other cell types. The neurones develop levels of choline acetyltransferase (CAT) activity comparable to those obtained for neurones grown with myotubes.

Ciliary ganglia from 7–8-d-old chick embryos (Hamburger–Hamilton stages 32–34) were dissociated with trypsin as previously described[4]. The cells were plated in collagen-coated,

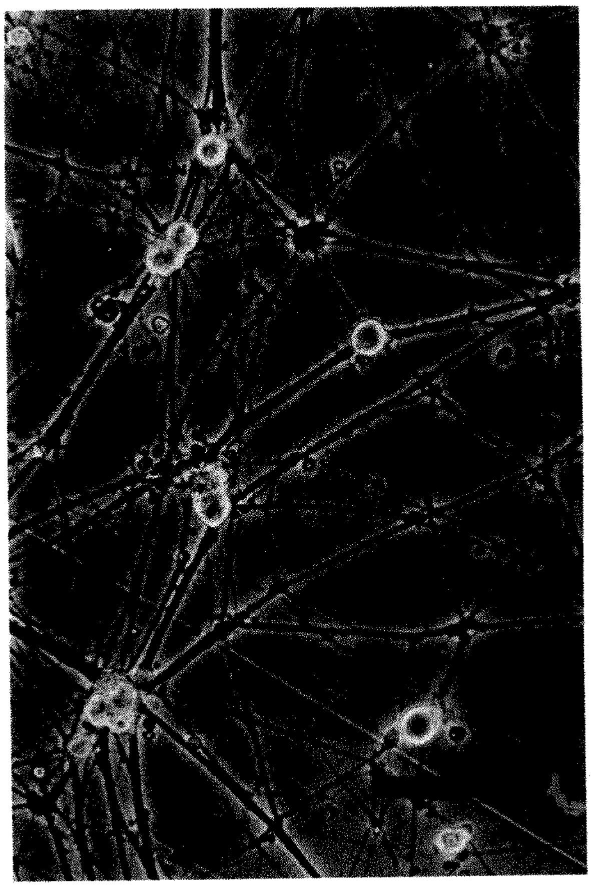

Fig. 1 Dissociated CG neurones after 3 weeks in culture. CG neurones dissociated from 8-d-old embryonic ganglia were maintained in heart-conditioned medium for 3 weeks. The photo was taken with phase contrast optics. Calibration bar: 100 μm.

Table 1 Culture medium requirements for survival of CG neurones

Culture medium	Neuronal survival (neurones per ganglion equivalent)	CAT activity (fmol ACh per neurone per h)
Conditioned + emb. ext.	6,900 ± 400	220 ± 24
Conditioned + emb. ext. + cytarabine	5,400 ± 200	ND
Unconditioned + emb. ext.	6,600 ± 100	370 ± 30
Conditioned	5,500 ± 400	170 ± 20
Unconditioned	0	ND

Cultures were seeded with ~6,500 neurones (1 ganglion equivalent) from 8-d embryos and were maintained for 11 d in the indicated medium. The cultures were then examined for surviving neurones and for CAT activity. Each value represents the mean ± s.e.m. of at least 7 cultures from 2 or more cell platings. Heart cell cultures were used to condition the medium where applicable. For these experiments only, embryo extract (emb. ext.) was not present unless indicated. Cultures treated with cytosine arabinoside (cytarabine) were exposed to a concentration of 10^{-5} M only during the first 2 d of the 11-d period. ND, not determined.

16-mm Falcon tissue culture wells at a density of 1 ganglion equivalent (~6,500 neurones) per well. Cultures plated at lower cell densities yielded variable results. Standard culture medium consisted of Eagle's minimal essential medium supplemented with 10% heat-inactivated horse serum (Microbiological Associates), 5% (v/v) chick embryo extract (prepared from 10-d-old embryos as previously described[4]), 50 μg ml^{-1} penicillin and 50 U ml^{-1} streptomycin. In our initial studies we used conditioned medium prepared by incubating standard culture medium with skeletal myotube or heart cell cultures for 72 h; the conditioned medium was passed through a Millipore filter before use.

When grown in conditioned medium, CG neurones rapidly extended processes and survived for many weeks in culture (Figs 1, 2*a*). Combining the cell counts for neurone cultures 1–3 weeks old yielded a value of 6,040 ± 160 (s.e.m. 52 cultures) for the mean number of surviving neurones per ganglion used to prepare the cultures. This represents 93% of the neurones previously shown to be present at the time of dissection[3]. Ganglionic non-neuronal cells seemed to be unnecessary for neuronal survival in these conditions, as few such cells were usually present (Fig. 1). Furthermore, 48-h exposure of the cultures to cytosine arabinoside, a drug that kills rapidly dividing cells such as ganglionic non-neuronal cells[5], only slightly reduced neuronal survival (Table 1).

Assays of CAT activity indicated that the neurones continued to develop along cholinergic lines. CG neurones grown with and without myotubes developed comparable levels of CAT activity, and the levels increased about 10-fold between days 3 and 15 in culture (Fig. 2*b*). Lactate dehydrogenase (LDH), a cytoplasmic enzyme common to many cell types, was assayed as a marker for cell cytoplasm. LDH activity increased three- to fourfold over the same period. Thus, at least a part of the increase in CAT activity represented an increase in specific activity (CAT/LDH), suggesting that neuronal development as well as net growth had occurred.

Survival of CG neurones was promoted independently by factors contributed by embryo extract in the medium and by factors derived from heart cells during the conditioning period. Unconditioned medium containing embryo extract supported complete neuronal survival and the development of high levels of CAT activity (Table 1). Nearly complete survival was also achieved in heart-conditioned medium lacking embryo extract, although lower levels of CAT activity were observed in this case. In unconditioned medium lacking embryo extract, the neurones failed to extend processes and degenerated after 1–2 d. It remains to be determined how many factors are involved and whether the heart cell factors are the same as those found in embryo extract. The differences in CAT activity per neurone observed for the various culture conditions (Table 1) raise the possibility that cholinergic development in the neurones may respond to different signals from those controlling neuronal survival. Other workers have described a factor in heart-conditioned F12 medium supplemented with 10% fetal calf serum that permitted neurite extension by CG neurones *in vitro*, but did not promote long-term survival in the conditions used[6–8].

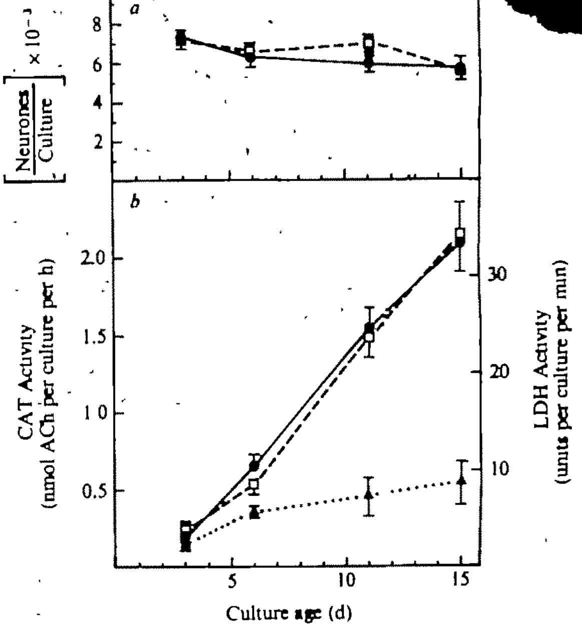

Fig. 2 Survival and development of CG neurones in culture. CG neurones from 8-d-old embryos were grown either with skeletal myotubes or alone with heart-conditioned medium. At the indicated times cultures were counted for neurones by examining 15 uniformly spaced fields of view at ×200 with phase contrast optics. Neurones were evenly distributed over the culture surface and could be distinguished by morphological criteria[4]. Such cells were previously confirmed to be electrically excitable[4] and could be autoradiographically labelled by high affinity ^{3}H-choline uptake[13]. ^{3}H-Thymidine autoradiography experiments demonstrated that CG neurones did not undergo cell division in culture (R.N. and D.K.B., unpublished observations). After counting the neurones, cultures were assayed for CAT and LDH activity as previously described[14]. Naphthyl vinyl pyridine (0.5 mM), a specific inhibitor of CAT, inhibited at least 80% of the activity. *a*, Neuronal survival; *b*, CAT and LDH activity. Neurones grown alone, □; neurones grown with myotubes, ●; LDH activity for neurones grown alone, ▲. Each point represents the mean ± s.e.m. for 7–10 cultures taken from 2–5 different cell platings. Background values for CAT and LDH activities were determined on culture wells treated identically to cell cultures except for the omission of cells; background values were always less than 10% of the culture values and were subtracted.

These results demonstrate that neither nerve–muscle synapse formation nor direct contact with muscle cells is necessary for the survival and development of CG neurones if appropriate factors are supplied in the culture medium. (The role of possible nerve–nerve synapses in such conditions[9] has not been examined.) Furthermore, it is clear that CG neurones are not irreversibly committed to cell death *in vivo*, even as late as the beginning of the normal death period. It might be argued that neurones in culture remain trapped at a developmental stage before that at which death occurs *in vivo*. We think that this is unlikely as the neurones innervated myotubes when present[4] and they developed high levels of CAT activity with or without myotubes. CAT activity on a per neurone basis at 15 d in culture was about five times greater than that reported for the sum of activity for the CG plus iris (postsynaptic target) tissue for 8-d embryos[10]. If the *in vivo* values could be corrected for contributions for preganglionic terminals, the comparison would be even vourable. CAT levels did not increase as rapidly in lture, however, as they did *in vivo*.

These findings are consistent with the suggestion that survival of parasympathetic neurones *in vivo* may be regulated in part by availability of a factor supplied by postsynaptic target cells[11]. Several lines of evidence support such a model for regulation of cell death for sympathetic neurones by nerve growth factor, although other interpretations of the data remain possible[12].

GABA and glycine may share the same conductance channel on cultured mammalian neurones

ANALYSIS of conductance fluctuations induced during application of putative neurotransmitters to postsynaptic membranes has led to estimates of the unitary conductance and kinetics of the underlying ionic channels. Estimates have been made for a variety of receptor-coupled channels activated on invertebrate and vertebrate membranes (for review see ref. 1). Recently we have applied the technique to mouse spinal neurones grown in tissue culture and have estimated the conductance and duration of the single channel events underlying responses to the putative inhibitory transmitter γ-aminobutyric acid (GABA)[2]. We have extended our studies to another inhibitory transmitter, glycine, and report here that channels activated by glycine have properties distinctly different from those activated by GABA and that the amino acid receptors may share a conductance mechanism.

Neurones were dissociated from the spinal cords of 13–14-d-old mouse embryos and grown in tissue culture[3] until large enough to be penetrated with two microelectrodes (20–25 μM cell bodies). Recordings were made on the modified stage of an inverted microscope using phase contrast optics at ×250 magnification. GABA and glycine were applied to the cell body by microiontophoresis. $MgCl_2$ was added to a final concentration of 10 mM to suppress spontaneous synaptic activity and allow easier examination of the postsynaptic events. The temperature of the experiments was 26 ± 1 °C. When recording with either KAc or KCl microelectrodes, the inversion potential of the GABA and glycine responses are identical, averaging about −63 mV with KAc microelectrodes and about −20 mV with KCl microelectrodes[4]. This difference in inversion potential for the two recording situations is a result of increased intracellular Cl^- concentration created by Cl^- leakage from KCl microelectrodes. Prolonged amino acid responses frequently reverse polarity when recorded with KAc microelectrodes, presumably due to the time-dependent change in driving force induced by sustained activation of Cl^- conductance[4]. In contrast, KCl recordings permit a relatively more stable, albeit altered, driving force. For these reasons fluctuation experiments have been carried out using KCl microelectrodes.

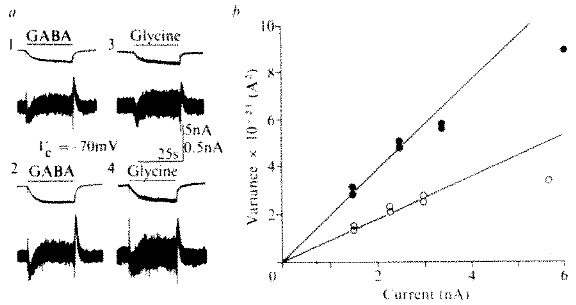

Fig. 1 GABA and glycine activate channels with different conductances on the same spinal neurone grown in cell culture. *a*, Membrane current recordings from a neurone voltage clamped to −70 mV show inward current responses during iontophoresis of GABA (1, 2) and glycine (3, 4). Iontophoresis duration is marked by bars above traces. Each pair of traces contains a d.c.-coupled trace above and a high-gain, a.c.-coupled trace below. Membrane current responses to GABA and glycine are associated with dose-dependent increases in the thickness of each trace, reflecting corresponding increases in conductance fluctuations. *b*, The variance in current fluctuation is directly related to the amplitude of the membrane current response to GABA (○) and glycine (●). Increases in variance obtained during the two sets of responses shown in *a* were computed along with those observed during two other amino acid responses and these plotted as a function of membrane current response. The first three points are approximated by straight lines whose slopes give estimates of single channel conductances of 16.4 pS and 36.4 pS for GABA and glycine, respectively. See text for explanation of deviations of the fourth points from the straight line.

Cells were voltage clamped so that the difference between the holding potential and the inversion potential for the amino acid responses (the driving force) was about 60 mV. Both amino acids caused a dose-dependent increase in inward current which was associated with a dose-dependent increase in the fluctuations of the current signal (Fig. 1). Amino acid-induced increase in variance was calculated by subtracting the baseline variance obtained before or after the iontophoretic application. This particular fluctuation analysis requires three basic assumptions: (1) the variance is derived from a statistical variation in the number of open ion channels activated by the amino acids about a mean level of open channels; (2) each ion channel event is rectangular and constant in amplitude; and (3) the probability of any channel being open is small[1]. With these assumptions an estimate of the single channel conductance, γ, can be made from measurement of the agonist-induced variance, σ^2, using the equation

$$\gamma = \sigma^2/(\Delta I(V_c - E_r))$$

where ΔI is the agonist-induced membrane current, V_c is the potential to which the cell is voltage-clamped and E_r is the reversal potential of the current response. Glycine current responses were associated with a larger variance than GABA current responses of similar amplitude. The first three points of both series of amino acid responses have been approximated by straight lines whose slopes give γ values of 15 and 29 pS for GABA and glycine, respectively. The fourth points fall below the straight lines, indicating an apparent decrease in γ. Both of the largest current responses were partially desensitised. The apparent decrease may reflect a large increase in the probability of non-desensitised channels being open, contrary to one of the assumptions on which fluctuation analysis is predicted. Estimates of γ were made for GABA and glycine applied to the

0028–0836/79/0277—0234$01.00

same spinal neurones ($n=4$) and to different spinal neurones ($n=12$ cells for GABA and 6 cells for glycine). When the amino acids were compared on the same neurone γ estimates were (mean ± s.d.) 14.7 ± 3 and 30.4 ± 8.4 pS for GABA- (71 observations) and glycine-activated channels (50 observations), respectively. Estimates made on separate cells were 18 ± 8.2 pS for GABA (271 observations) and 30.4 ± 9.5 pS for glycine-activated channels (71 observations).

Channel duration estimates were made by performing spectral analyses of baseline and amino acid-induced fluctuations and then subtracting the former from the latter power density spectra. Power density spectra were calculated as the Fourier transform of at least 8,192 point samples of the fluctuations digitised at 1, 2 or 5 ms per point[5]. Spectra of GABA- and glycine-induced fluctuations could usually be approximated by a single lorentzian of the form $S(f)/S(0)=1/[1+(f/f_c)^2]$, where $S(f)$ is the spectral density as a function of frequency, f, and f_c is the frequency where the spectral density has decreased to half the value of the zero-frequency asymptote, $S(0)$, of the spectrum. Such an approximation is consistent with the hypothesis that the fluctuations arise from a single population of channels whose duration is exponentially distributed. The average channel duration, τ, compared on the same four neurones was (mean±s.d.) 26.7 ± 7.7 ms (71 observations) and 4.8 ± 1.3 ms (50 observations) for GABA- and glycine-activated channels, respectively. Estimates of durations derived from amino acid responses obtained on different neurones were 20 ± 6.6 ms for GABA- (271 observations) and 5.2 ± 1.6 ms for glycine-activated channels (71 observations).

From these results it is clear that single channel properties activated by GABA and glycine are not identical, with GABA-induced events being lower in conductance and longer in duration than those induced by glycine. The differences in the properties of the single channel events may reflect differential binding of the amino acids to the same receptor–channel complex, as has been suggested to account for different single channel events activated by various cholinergic agonists applied to endplate regions of muscle membranes[6]. However, a single receptor site for neutral amino acids on spinal neurones is not supported by several lines of investigation. Convulsant drugs can selectively antagonise the pharmacological responses of spinal and sensory neurones to either of the amino acids without affecting responses to the other[7–10]. The amino acids do not affect each other's affinity for receptor sites as reflected in binding studies on membranes extracted from the central nervous system (refs 11–13 and E. J Peck, personal communication). Structure–activity studies with conformationally restricted GABA analogues have indicated an 'active conformation' of GABA which cannot be matched by any configuration of glycine[14]. Some membranes respond to GABA but not to glycine[15,16]. We have also found a selective antagonism of the amino acid responses on cultured spinal neurones by specific convulsants (refs 17, 18 and unpublished observations) and a selective enhancement of GABA responses by barbiturates[19,20] and benzodiazepines[21]. Cultured cells grown in the presence of GABA respond to glycine but not GABA, while cells grown in glycine respond to GABA, but not glycine[22]. These findings, coupled with the present results, suggest that the different single channel properties activated by GABA and glycine reflect engagement of physically distinct receptor–channel complexes on neuronal membranes.

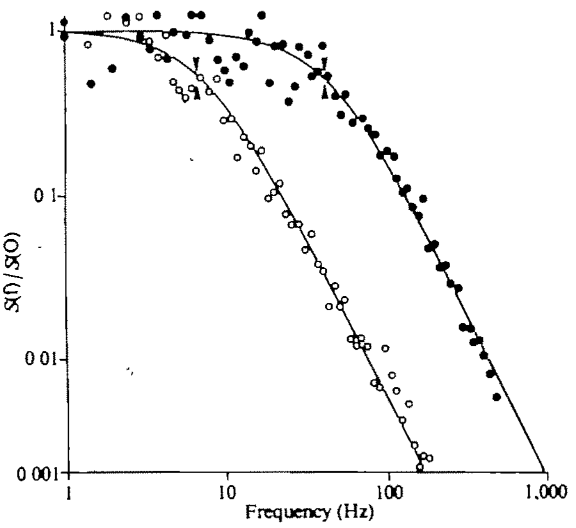

Fig. 2 Power density spectra of amino acid-induced current fluctuations show different durations for GABA- (○) and glycine- (●) activated channels. These spectra were calculated from results obtained on the same spinal neurone as in Fig. 1. The spectra shown are the differences between spectra derived from amino acid-induced fluctuations and those derived from baseline fluctuations. They have been normalised by dividing each spectral density point, $S(f)$, by the zero-frequency asymptote of the spectrum, $S(0)$. Points across frequency bands have been averaged to smooth the spectra. The points are approximated by lorentzians (solid lines) of the form $S(f)/S(0)=1/[1+(f/f_c)^2]$. Double arrowheads indicate the half-power frequency, f_c which is related to mean channel duration, τ, by $\tau=\frac{1}{2}\pi f_c$. In this cell, f_c for GABA is 6.5 Hz and f_c for glycine is 41 Hz, corresponding to channel durations of 24.5 and 3.9 ms, respectively.

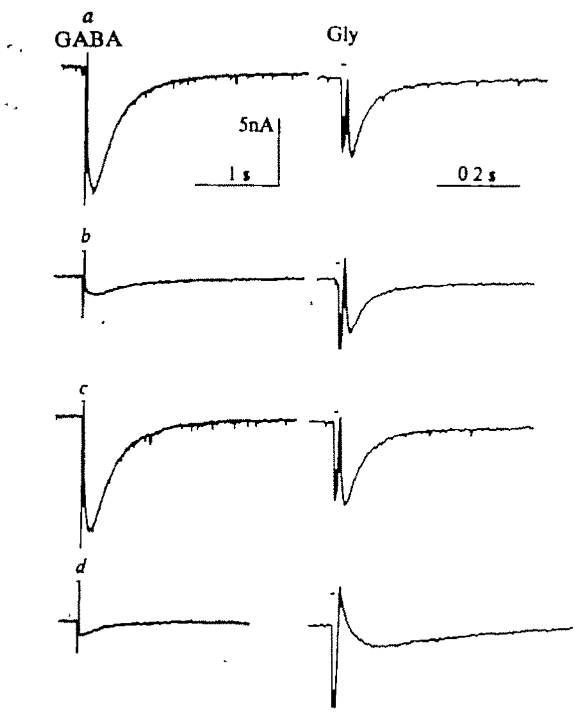

Fig. 3 GABA and glycine interact on cultured spinal neurones The cell illustrated was voltage clamped to −80 mV and GABA and glycine iontophoresed either separately (*a*, control; *c*, recovery) or together (*b*, during prolonged iontophoresis of GABA; *d*, during prolonged iontophoresis of glycine). The amplitude of the GABA current response is markedly depressed and its time course slowed when superimposed on a prolonged, desensitising dose of GABA (*b*, left-hand trace). A depression of the glycine current response without apparent change in time course is also evident during prolonged GABA iontophoresis (*b*, right-hand trace). Conversely, the GABA response is markedly depressed without apparent change in time course during prolonged glycine iontophoresis (*d*, left-hand trace). The glycine response is also considerably depressed and its time course slowed during the prolonged, desensitising glycine application (*d*, right-hand trace).

This notion is not supported by observations made on amino acid current responses elicited on membranes acutely desensitised to one or the other amino acid. For example, sustained applications of GABA induced a current and conductance response which rapidly desensitised. Current and conductance responses to glycine iontophoresed onto membranes desensitised to GABA were depressed in a reversible manner relative to those obtained in the absence of GABA, while the time course of the responses did not seem to be altered (Fig. 3*a–c*). (The time course of desensitised GABA and glycine responses was always slower than those obtained in control.) Conversely, sustained application of glycine sufficient to induce desensitisation of glycine responses reversibly depressed the current and conductance response to GABA relative to control with little change in its time course (Fig. 3*d*). Similar depressions of one amino acid response during sustained iontophoresis of the other were observed in each of 11 spinal cord cells where the interaction was examined. The depressions of the amino acid responses were not associated with a change in the driving force for the amino acid responses (unpublished observations).

One explanation for these results is that both amino acids can compete for each receptor site but only activate conductance at the appropriate receptor. The inappropriate amino acid would thus interfere with channel activation by the appropriate amino acid at the receptor. However, a variety of studies have failed to show an interaction between the amino acids (refs 11–13, 22, E. J. Peck, personal communication) and we have found that GABA responses elicited on cultured dorsal root ganglion cells are not altered by sustained application of glycine, which does not affect the membrane properties of the cells (unpublished observations). Thus, it seems unlikely that the interaction takes place at the receptor level. Alternatively, GABA and glycine receptors may share a common channel which can still be activated by glycine when GABA receptors are largely desensitised but which is difficult to activate by GABA when glycine receptors are only partially desensitised and thus almost continuously using these channels. This latter explanation suggests that postsynaptic Cl^- conductance mechanisms might be coupled to several amino acid receptors and that the properties of the resulting single channel event are determined by the type of amino acid released from presynaptic terminals.

We thank Mr William Vaughn for computer programming, Drs Harold Lecar and T. G. Smith, Jr for criticisms of the manuscript, and Mrs Mary Lou Adams and Mrs Gloria Hall for typing.

Acetylcholine receptors in organ-cultured human muscle fibres

ORGAN culture of nerve and muscle facilitates investigations which cannot easily be carried out *in situ*[1,2]. We have developed a method for maintaining human muscle in organ culture which should allow us to investigate normal as well as various pathological properties of muscle fibres. We report here the use of these preparations to compare junctional and extrajunctional channels, induced by acetylcholine (ACh), in human muscle. In addition we have made a preliminary study of miniature endplate currents, in normal and myasthenia gravis endplates, following organ culture.

Human intercostal nerve-muscle obtained from myasthenia gravis and control patients was dissected in sterile conditions to give small bundles of fibres (~100). Fibre bundles were pinned through their tendons and mounted, under slight tension, on Sylgard frames. They were maintained in Trowell's T-8 culture medium (Gibco) or Dulbecco's minimal essential medium (Gibco) containing 100 IU ml^{-1} penicillin and streptomycin and 0.02 mM glutamine in an atmosphere of 95% O_2/5% CO_2 (ref. 3). Cultured muscle fibres had 'overshooting' action potentials and resting potentials of over 70 mV, and remained viable for periods of at least 2 weeks at a constant temperature of 23 °C. At this temperature the rate of metabolism is greatly reduced[4]. Electrophysiological methods were as previously described[5].

Extrajunctional ACh sensitivity was studied at the muscle–tendon junction, where it is known to occur in other species[6,7]. A voltage recording intracellular microelectrode was inserted near the tendon to measure the response to a 1–2 nC ionophoretic pulse of ACh applied to the surface of the fibre. The ACh pipette was moved in steps of 50–100 μm (Fig. 1). Some fibres (approximately 5–50%) of normal human muscle were found to have a marked ACh sensitivity at the tendon junction. The sensitive area covered a length of ~800 μm, that is, a small fraction of the total fibre length of approximately 1–2 cm. The peak of sensitivity sometimes occurred several hundred μm away from the

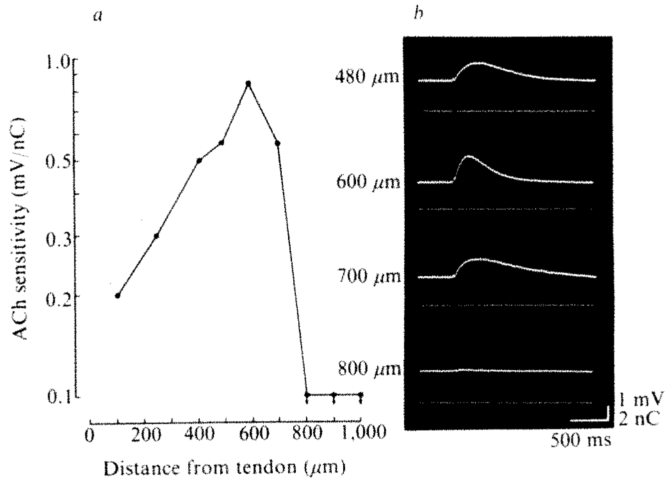

Fig. 1 *a*, Distribution of extrajunctional acetylcholine sensitivity, at the muscle–tendon junction of a fresh normal human muscle fibre, measured in response to 2 nC pulses of ACh applied from a micropipette at various distances from the tendon. Note that the peak of sensitivity in this fibre apparently occurs at 600 μm from the tendon although the presence of connective tissue in the tendon region makes the actual site of peak sensitivity uncertain. At 800 μm or more from the tendon, sensitivity was undetectable. *b*, Examples of the potential changes produced by ACh applied to the tendon region (at 480, 600, 700 and 800 μm from the tendon); same experiment, as shown in graph. The drug ejection currents passing through the micropipette are monitored on the lower trace in each pair. Calibration 1 mV or 2 nC, 500 ms.

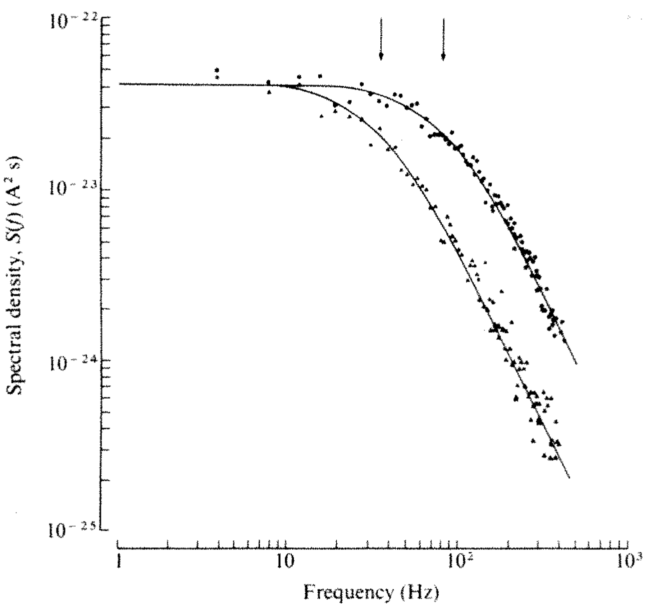

Fig. 2 Power spectra of current noise produced by steady ionophoretic application of acetylcholine to a voltage clamped endplate (●) and an extrajunctional site at the muscle–tendon junction (▲) in human muscle cultured at 23 °C for 5 d. The spectra are from two fibres, in the same bundle, at clamp holding potential $V_m = -80$ mV, temperature, 21 °C. Endplate spectrum (●) was obtained from 136 averaged spectra (four noise runs). Half-power frequency indicated by arrow is $f_c = 87$ Hz, hence $\tau_{noise} = 1.8$ ms. Mean current, $\mu_I = 19.7$ nA and the single channel conductance calculated from the fitted lorentzian curve is, $\gamma = 25.14$ pS. Extrajunctional spectrum (▲) was obtained from 76 averaged spectra (three noise runs). Half-power frequency indicated by arrow is $f_c = 35$ Hz, hence $\tau_{noise} = 4.5$ ms. Mean current, $\mu_I = 4.8$ nA and the single channel conductance calculated from the fitted curve is, $\gamma = 11.75$ pS. Vertical axis applies to the extrajunctional spectrum; multiplication of the ordinate values by 3.03 gives the spectral density values (A^2 s) for the endplate noise. After feeding into a 1,000-Hz active ($1/f^8$) low pass filter, data was digitalized at 2,000-Hz sample rate and edited to remove spontaneous miniatures and artefacts. Control noise, taken immediately before application of ACh, has been subtracted. Fast Fourier transform was calculated for 512 point segments. The single channel conductance was normally estimated from both the variance, σ^2, of the current noise and the zero frequency asymptote, $S(0)$, of the spectrum; $\gamma = \sigma^2/\mu_I(V_m - V_{eq})$ and $\gamma = S(0)f_c/\mu_I(V_m - V_{eq})$ where the equilibrium potential, V_{eq}, for ACh was taken as zero mV.

tendon (Fig. 1). Normally, sensitivity was not detectable between the tendon junction and the endplate. Fibres cultured for up to 14 d did not acquire sensitivity in this region. Also, in only one out of eight cultures kept at 36 °C for up to 14 d did we find evidence for denervation supersensitivity. This is in sharp contrast to what has been found in rat muscles which rapidly acquire supersensitivity in the whole fibre after denervation in similar culture conditions[2].

Acetylcholine sensitivity was not detected in the muscle tendon region of any of the myasthenic muscles studied (16 fibres, 3 muscles). This is probably related to the same process which causes reduced ACh sensitivity of endplates in myasthenic fibres.

Properties of junctional and extrajunctional channels were compared in normal human muscle cultured at 23 °C by analysing the voltage clamped noise[8-10] which occurred during steady ionophoretic application of ACh to a junctional site or to a tendon region. Power density spectra of current fluctuations are shown in Fig. 2. In most cases spectra were fitted with a single lorentzian component (1/frequency^2), and the frequency, f_c, at which the power is reduced to one half of its maximum value, gave the mean life-time of the open channel, τ_{noise}, according to $\tau_{noise} = 1/(2\pi f_c)$. Power spectra of junctional and extrajunctional noise are similar in form (Fig. 2) but their half-power frequencies differ revealing that the open-state of extrajunctional channels is prolonged when compared with that of endplate channels.

In the example shown in Fig. 2 extrajunctional channels have a mean life-time of 4.5 ms compared with 1.8 ms for the junctional channel from the same muscle. The mean open-time of junctional channels in culture was τ_{noise} (junctional) = 1.55 ± 0.08 ms ($n = 7$ fibres); the comparable value for extrajunctional channels was τ_{noise} (extrajunctional) = 3.52 ± 0.27 ms ($n = 5$ fibres), $V_m = -80$ mV, temperature, 21 °C. The single channel conductance, γ, derived from both the variance of the current noise and the zero frequency asymptote of the spectra, was in the range 20–25 pS for endplate channels and 11–16 pS for extrajunctional channels. The values of these channel parameters are similar to those obtained in the same muscles before culturing (see also ref. 11).

In both normal and myasthenic endplates miniature endplate currents (m.e.p.cs) are present for 5–7 d in muscles cultured at 23 °C indicating the time required for denervation of the endplates. It was therefore possible to assess the sensitivity of fresh and cultured endplates by comparing their m.e.p.c. amplitudes. Myasthenic m.e.p.cs are small apparently due to binding of

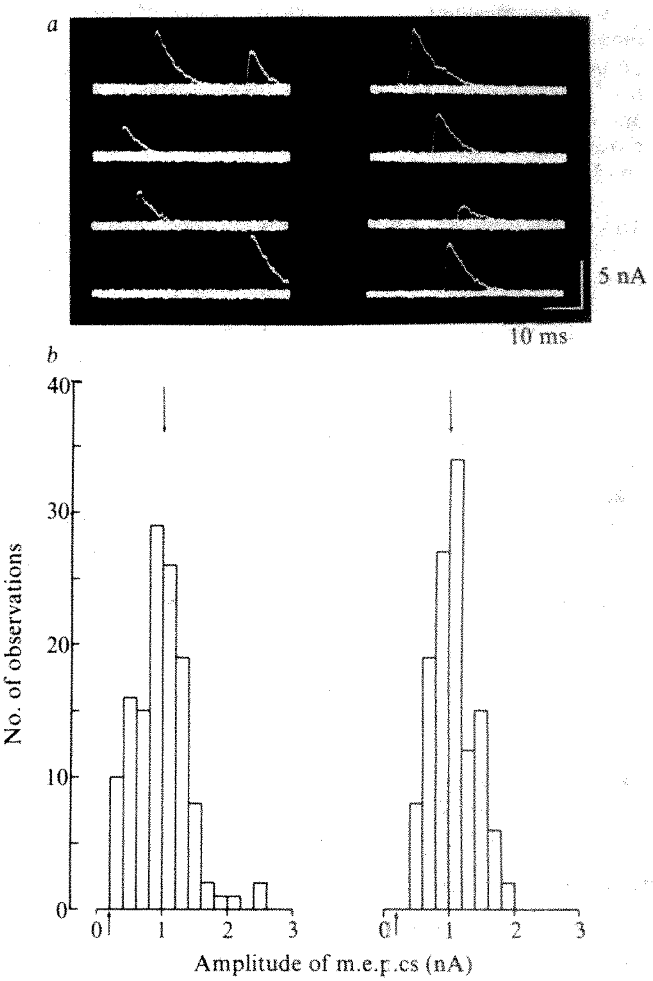

Fig. 3 *a*, Examples of miniature endplate currents at a fresh normal human endplate (left) and at an endplate from the same muscle after 5 d in culture (right). m.e.p.cs were recorded under voltage clamp ($V_m = -80$ mV, temperature, 21 °C) in the presence of prostigmine 2×10^{-7} g ml^{-1} through a 500-Hz low pass filter which prolongs the rising phase and slightly attenuates the amplitude. Calibration, 5 nA and 10 ms. *b*, Amplitude distributions of m.e.p.cs at a voltage clamped myasthenic human endplate in fresh muscle (left) and at an endplate from the same muscle after 6 d in culture (right). Mean m.e.p.c. amplitude (arrows) at the fresh endplate = 0.99 ± 0.06 nA (mean ± s.e.m.); mean m.e.p.c. amplitude at an endplate after 6 d culture = 1.06 ± 0.03 nA. m.e.p.cs were obtained in the presence of prostigmine 2×10^{-7} g ml^{-1} ($V_m = -80$ mV, temperature, 21 °C). Background noise level is indicated by arrows on abscissa.

anti-receptor antibodies to the ACh-receptor[12], which may cause a loss of functional receptors[13,14], and also a reduction in their number through an increased rate of degradation[15-17]. As circulating anti-receptor antibody occurs in the plasma of myasthenic patients[18], the possibility arises that in its absence the m.e.p.cs would increase in amplitude if antibody could detach from receptors or if new receptors were incorporated into the membrane; although the latter process should be far from optimal in culture conditions at 23 °C.

The amplitude of m.e.p.cs at normal human endplates is not markedly changed after 5–6 d in our culture conditions. Figure 3*a* shows examples of m.e.p.cs recorded from a voltage-clamped normal endplate at zero culture time and from another endplate in the same muscle 5 d later ($V_m = -80$ mV, temperature, 21 °C, prostigmine 2×10^{-7} g ml^{-1}). In cultures of three myasthenic muscles there was no marked change in m.e.p.c. amplitudes after 5–7 d. Amplitude distributions of myasthenic m.e.p.cs from one endplate before culture and from another endplate in the same muscle 6 d later are shown in Fig. 3*b*.

We conclude that extrajunctional ACh receptors are normally present in some adult human muscle fibres and that the channels they operate differ from endplate channels in their kinetic properties. This is analogous to the situation in denervated frog[8,19], rat and mouse[20] muscle where properties of junctional and extrajunctional channels show differences comparable to those described here. However, the single channel life-time and conductance of the extrajunctional channels in adult human muscle are smaller than those in cultured human myotubes[21]. This dissimilarity as well as that between junctional and extrajunctional receptors in adult fibres may reflect differences in the receptor molecules themselves or in their membrane environment.

Finally our experiments indicate that if some of the reduced ACh sensitivity of myasthenia gravis endplates results from binding of an anti-receptor antibody, as has been suggested, then the antibody–receptor combination is practically irreversible when the muscle is maintained at 23 °C or the antibodies may unbind but leave the receptors still in a non-functional state.

We thank Mr. J. R. Belcher, Dr J. Newsom Davis, Mr. M. F. Sturridge, and Dr A. Vincent for their cooperation and the MRC for support. We are grateful to the patients for their collaboration. Is the red cell calcium pump regulated by ATP?

THE very low physiological level of calcium in the human red cell is maintained by a powerful ATP-fuelled Ca extrusion pump which has been extensively studied[1]. Recently evidence has been accumulating that the kinetic properties of the active Ca flux and associated (Ca+Mg)ATPase activity depend very much on the experimental conditions and/or the manner of preparation of the red cell membranes or resealed ghosts[2-4]. The variability may reflect the nature or degree of interaction between the membrane Ca pump and a cytoplasmic activator protein described recently[5-7], which could be involved in regulation of physiological Ca levels. In previous work with whole red cells[8,9] or resealed ghosts[10] the concentrations of the major Ca pump ligands, ATP and/or Ca, have been changing during the course of the reaction. Because of the possible importance of the ligand conditions in assessing the physiological functioning of the Ca pump, we have looked at (Ca+Mg)-dependent ATP hydrolysis in resealed ghosts with buffered ATP and Ca levels and at the active Ca flux with a buffered ATP level. The experiments reported here show that both the ATP hydrolysis and the Ca flux are activated with two distinct ATP affinities and this raises the possibility of regulation of the Ca pump by ATP in the region of the lower affinity.

For the ATPase measurements, the internal ATP concentration was clamped at a fixed level by incorporating [γ-^{32}P]ATP and a regenerating system into the ghosts. The regenerating system consisted of creatine kinase and creatine phosphate in chemical and isotopic equilibrium with the ATP. The method (details of which are given in the legend to Fig. 1) was developed previously[11] and has the advantage of allowing measurement of ATP hydrolysis at very low concentrations. The free Ca levels in the cells were maintained in the range 10^{-8} to 10^{-4} M by incorporating Ca buffers into the cells and equilibrating the Ca concentrations across the membranes by means of the Ca-ionophore A23817. Figure 1 shows a time course of ^{32}Pi release in cells prepared to contain 50 μM ATP and about 6 μM free Ca^{2+}. Measurements of the internal Ca by flame photometry showed that it was approximately equal to the external Ca concentration at the beginning of the test incubation and remained constant (not shown). The rate of ^{32}Pi release was constant for about 15 min during which time the total ATP content of the ghosts must have turned over about 40 times. Linearity has been observed regularly at 1–1,000 μM ATP demonstrating effective regeneration of ATP even at the high rates of ATP hydrolysis observed.

In several experiments in which ghosts were prepared to contain different Ca-buffer mixtures, and either 10 or 500 μM ATP, the free Ca^{2+} concentration which sustained the half-maximal ATPase activity was about 0.2 μM, that is, a 'high affinity' (see refs 3, 4).

Figure 2 shows the rate of (Ca+Mg)-dependent ATP hydrolysis as a function of the total ATP concentration in cells, with an optimal but relatively low free Ca^{2+} concentration of 6.3 μM. The curve is clearly biphasic. The kinetic parameters calculated from the curve show a high affinity component with K_m 1–2 μM and a V_{max} of about 4.7 mmol per l cells per h, and the low affinity region has a K_m of about 180 μM with an overall maximal rate of about 16 mmol per l cells per h. The rate of ATP hydrolysis in resealed ghosts without Ca, that is Mg-dependent ATPase, was subtracted from the total activity with Ca and Mg at all ATP concentrations. The rate of Mg-ATPase did not vary between 10 and 500 μM ATP and the measured value of 0.8 mmol per l cells per h was used to make the correction. The rate of (Ca+Mg)ATPase is presumably somewhat underestimated at very low ATP concentrations (<10 μM) but this does not alter the activation pattern.

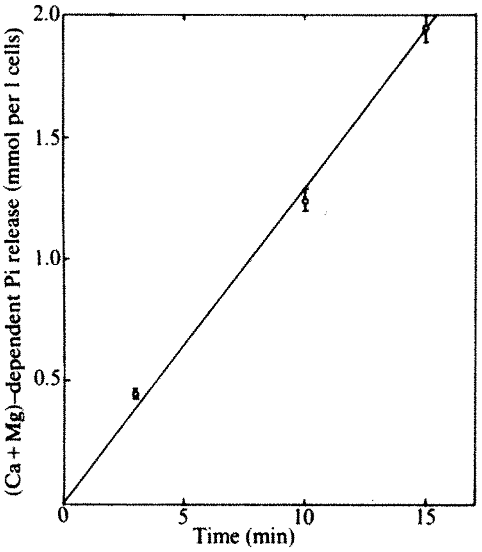

Fig. 1 (Ca + Mg)-dependent ATP hydrolysis in resealed red cells containing buffered concentrations of Ca^{2+} ions and ATP. See ref. 11 for details. Preparation of [γ-^{32}P]ATP and ^{32}P-creatine phosphate in chemical and isotopic equilibrium: 250 μM of ATP(containing [γ-^{32}P]ATP 1×10^6 c.p.m.) was added to 1 ml of a solution containing 50 mM creatine phosphate, 0.5 mM creatine, 12.5 mM $MgCl_2$, 25 mM inosine, 0.5 mM ouabain, 50 mM HEPES (Tris) (*p*H 7.4 at 22 °C) and 25 units of creatine kinase and hexokinase. After 1 h incubation at 37 °C, 5 μmol of HEDTA (*p*H 7.4 at 22 °C) was added, the solution was diluted 5 times and kept at 0 °C. Preparation of resealed ghosts and measurement of ATP hydrolysis: red blood cells were washed 3 times with a standard 'wash solution' which contained: 130 mM NaCl, 10 mM KCl, 2.5 mM $MgCl_2$ and 10 mM HEPES (Tris) (*p*H 7.4 at 22 °C). The cellular ATP was depleted by incubating the cells for 60 min at 37 °C in a medium containing 6 mM inosine and 6 mM iodoacetamide. The cells were then washed 3 times at room temperature to remove inosine and iodoacetamide and packed at 1,500*g* for 10 min. Packed cells were lysed in 9 times their own volume of the diluted ice-cold solution containing the ATP regeneration system. After 2 min 2 M NaCl was added to restore the tonicity to 310 ideal milliosmolar, and the ghosts were incubated at 37 °C for 10 min. The resealed ghosts were then washed 3 times, the first and third time with ice-cold medium and the second wash at room temperature. The final intracellular concentrations were: NaCl, 130 mM; $MgCl_2$, 2.5 mM; HEDTA, 1 mM; ATP (+[γ-^{32}P]ATP), 50 μM; creatine phosphate, 10 mM; HEPES (Tris), 10 mM *p*H 7.4; creatine, 100 μM; ouabain 0.1 mM; creatine kinase 5 units per ml and hexokinase 5 units per ml. The ghosts were packed at 25,000*g* for 1 min, suspended to 3–5% haematocrit in ice-cold wash solution containing 0.1 mM ouabain, and $CaCl_2$ 0.71 mM plus HEDTA 1 mM, calculated to give 6.3 μm free Ca^{2+} (see ref. 12). Ca ionophore (A23187) was then added to a final concentration of 10 μM and the ghosts were incubated for 20 min at 0 °C and for 5 min at 37 °C before the measurements were begun. At various times at 37 °C the ATP hydrolysis was terminated by the addition of glucose to a final concentration of 15 mM and further 10 min incubation at 37 °C (this converts the remaining creatine phosphate and ATP to glucose-6-phosphate). The membranes were precipitated by 5% perchloric acid. 1 ml of membrane free extract was shaken for 30 s with 4 ml 0.5% ammonium molybdate in 5% (w/v) perchloric acid and 2 ml isobutanol, and the tubes were centrifuged at 1,000*g* for 30 s. Measured portions of the isobutanol layer were transferred to vials containing 0.5 ml of 2 M Tris solution and 8.5 ml Bray's scintillation fluid, and counted. The total ^{32}P counts were estimated by boiling 1 ml of the ghost suspension with 1 M HCl for 15 min and extracting ^{32}P as above. The rate of ATP hydrolysis is calculated from the fraction of breakdown of total phosphate substrate (creatine phosphate + ATP) per given time. Each point represents the average value ± 1 s.e.m. from tubes incubated in triplicate.

Experience showed that to observe biphasic curves the free Ca^{2+} within the cell must be less than about 1 mM. At higher concentrations (3–6 mM) we have observed an apparent hyperbolic saturation by ATP with a K_m of 5–10 μM and a severely depressed maximal rate of 3–6 mmol per l cells per h. The difference in the observed type of behaviour at low and high Ca is attributable to this inhibitory effect of high Ca concentrations, which is much more effective at the higher ATP concentrations than in the low ATP concentration range (not shown).

The curve in Fig. 2 could indicate that ATP combines twice with the Ca pump per turnover but it might also be explained by the action of two different (Ca + Mg)-dependent enzymes with only one involved in Ca transport. It was therefore also important to look at the ATP dependence of the active Ca flux. For the flux experiment of Fig. 3 the ATP levels were buffered again by the use of the creatine phosphate–creatine kinase system and the cells were loaded with 2.5 mM Ca(+ ^{45}Ca). Here, of course it is not possible to use the ionophore and so the internal Ca concentration drops during the course of the incubation. The cells in this experiment contained less than 1 mM total Ca immediately before the test incubation. The rate of ^{45}Ca efflux was constant for 5–15 min at the different ATP concentrations. A biphasic behaviour is clearly observed. The kinetic parameters for the two regions are respectively $K_m \approx$ 2 μM, V_{max}, 2.2 mmol per l cells per h and $K_m \approx 190$ μM with an overall V_{max} of 7.3 mmol per l cells per h. Again if much higher initial Ca concentrations were used the biphasic pattern could not be clearly distinguished. In Fig. 3 the rates of Ca efflux are appreciably lower than the ATPase measured with low free Ca^{2+} concentration plus ionophore (see Fig. 2). This is due to a significant inhibitory effect of Ca even at the 0.5–1 mM level present in the flux experiment. The Ca inhibition seems to affect the V_{max}, or turnover rate of the Ca pump without altering the apparent affinities or K_m for ATP. In parallel measurements of ATP hydrolysis estimated as in Fig. 2 but without ionophore, and Ca flux, made with ghosts containing 0.5–1 mM Ca^{2+} and 10 μM or 500 μM ATP, we have observed a ratio of Ca efflux to (Ca + Mg)-dependent ATP hydrolysis of 0.93 and 1.08 at the two ATP concentrations. This confirms the figure reported originally by Schatzmann[10].

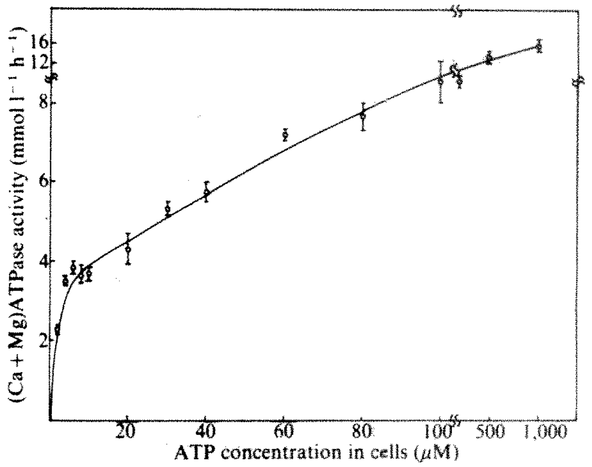

Fig. 2 ATP dependence of the (Ca + Mg)ATPase in resealed ghosts. Ghosts were prepared essentially as described in the legend to Fig. 1 except that: (1) the cells had been starved for 24 h at 37 °C in the glucose free wash solution containing also 0.2 mM EGTA with no added Ca, and chloramphenicol (25 μg ml^{-1}), before a 2-h incubation with inosine and iodoacetamide; and (2) the lysing solution contained the appropriate concentrations of [γ-^{32}P]ATP, together with the ATP regeneration system. For measurement of (Ca + Mg)ATP hydrolysis the cells were incubated at 37 °C for 15–60 min according to their ATP concentration. The rate of Mg-dependent ATP hydrolysis was measured over a 120 min incubation period in cells containing 10 μM or 500 μM ATP, and 1 mM EGTA.

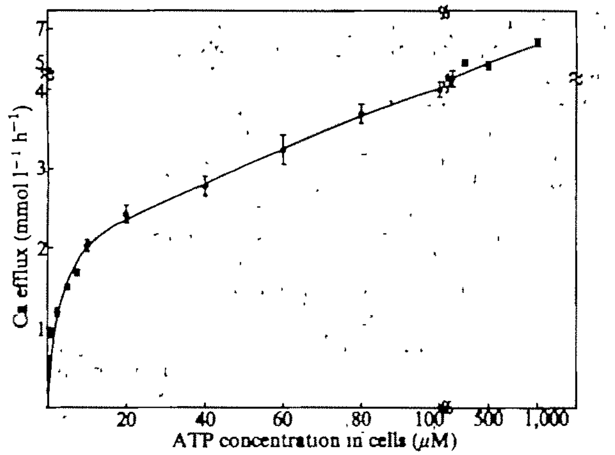

Fig. 3 ATP dependence of active Ca efflux from resealed ghosts. Red cells were washed as in the legend to Fig. 1 and starved as described in the legend to Fig. 2. 0.5 ml of packed starved red cells was lysed in 4.5 ml of ice-cold lysing solution containing: ATP, 1–1,000 μM as indicated, creatine phosphate, 10 mM creatine kinase 25 units. $CaCl_2$ (containing ^{45}Ca 2×10^6 c.p.m.) 2.5 mM; HEDTA, 1 mM; $MgCl_2$, 2.5 mM; HEPES (Tris), 10 mM(pH 7.4 at 22 °C); inosine, 5 mM; and ouabain 0.1 mM. After 2 min 2 M NaCl was added to restore tonicity to 310 ideal milliosmolar. The cells were incubated for 10 min at 37 °C and washed as in the legend to Fig. 1 (EGTA, 0.5 mM was added to the warm wash solution). The cells were then suspended at 2–3% haematocrit in ice-cold wash solution. The Ca flux was initiated by transferring the tubes to a 37 °C water bath. At various times the efflux was terminated by removal of 0.5 ml of the suspension into 0.7 ml of ice-cold wash solution containing 170 μM $LaCl_3$. The cells were spun down for 2 min at 12,000g in an Eppendorf Microcentrifuge, and 1 ml supernatant was transferred into vials containing 9 ml of Brays scintillation fluid, and counted. Radioactivity in the supernatant at zero time was subtracted from that at all other incubation times. The total ^{45}Ca counts present initially in the cells was obtained by allowing complete efflux in a 2-h incubation at 37°C. The concentration of Ca in the cells before the 37°C incubation was estimated either from the total radioactivity per known volume of cells and the specific activity of the ^{45}Ca in the lysing solution, or by flame photometry. For the latter measurement 50 μl of ghosts of known haemotocrit (25–50%) were lysed in 1 ml of perchloric acid 1.5% w/v. The precipitated protein was spun down and the supernatant Ca was read against standard $CaCl_2$ solutions, 25–100 μM made up in 1.5% PCA and the appropriate volume of wash solution (containing NaCl) added with the cell suspension Both methods give similar results. In the experiment of Fig. 3 the initial Ca concentrations were 0.8–1.1 mM. The rate is calculated from the fractional efflux of the total Ca per given time. Each point represents the average value ±1 s.e.m. from tubes incubated in triplicate.

The biphasic ATP activation curve and the constancy of the ratio of Ca flux to ATP hydrolysis at 10 and 500 μM ATP suggest strongly that the ATP hydrolysis at both high and low ATP levels (Fig. 2) is involved in the working of the Ca pump.

In previous observations of ATP activation of the ATPase, using broken membranes somewhat conflicting results have been reported. Wolf[13] and Schatzmann[14] observed an apparent simple saturation behaviour with K_m values for Mg-ATP in the range 20–50 μM. Wolf *et al.*[15], working with a partially purified (Ca+Mg)ATPase, and Sharff and Foder[16], have reported Hill coefficients of <1 for activation by ATP but no evidence for a very high affinity activation as in the present resealed ghost experiments. On the other hand Sarkadi *et al.*[17], looking at the active Ca flux in inside-out vesicles have seen a high ATP affinity. It seems possible that the differences between the resealed ghosts and broken membranes reflect changes that occur during the membrane preparations or result from the inhibitory effects of high Ca^{2+} mentioned above.

The reaction mechanism of the Ca pump-associated (Ca+Mg)ATPase involves a phosphorylated intermediate[18]. Rega and Garrahan[19] have shown that formation of the phosphoenzyme requires ATP at 1–2 μM, that is, in the high affinity range. Thus it seems possible that the increase in the turnover rate at the higher ATP concentrations is a regulatory function of the nucleotide acting in a non-phosphorylating role. The cell membrane (Na+K)ATPase is phosphorylated by ATP acting at a high affinity site and in addition an extra non-phosphorylating function of the ATP at a low affinity site is well documented for both kidney membranes[20] and resealed red cells where we previously reported biphasic ATP activation curves[11]. The non-phosphorylating function of ATP involves regulation of the rate of a conformational transition, which is probably involved in the transport of K^+ ions[20–22].

As the membrane Ca pump and Na pump show a number of similarities in the reaction mechanism it would be interesting if regulation of transport linked conformational changes by ATP is found to be another common feature of the active cation pumps.

Physiological correlation between lactate dehydrogenase genotype and haemoglobin function in killifish

ERYTHROCYTE organic phosphate concentration is known to be an heritable trait in both humans and rats[1–3]. In humans this trait has been correlated with genetic variability of both pyruvate kinase and hexokinase[2]. However, similar phenomena have not been reported in lower vertebrates. During our studies on the allosteric regulation of fish haemoglobins by ATP (ref. 4) we observed significant variability in red cell ATP concentrations among individuals of the killifish *Fundulus heteroclitus*, and wondered whether this variability in organic phosphate could be the result of a genetic component. Consequently, we analysed *F. heteroclitus* for red cell ATP, concomitantly screening for enzyme variants. We report here that not only are ATP levels under genetic control, but they are also highly correlated with lactate dehydrogenase (LDH) phenotype. To our knowledge, this is the first such correlation reported. Moreover, as ATP is the major allosteric modifier of *F. heteroclitus* haemoglobin–oxygen affinity[5,6], this study provides a basis for an association

0028-0836/79/0277—0240$01 00

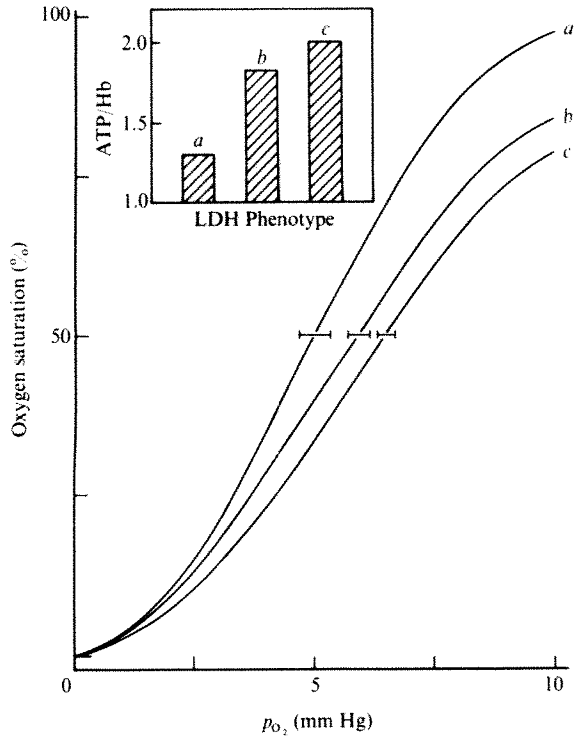

Fig. 1 Oxygen equilibria curves for whole blood from *F. heteroclitus* determined with an Aminco oxygen dissociation analyser. The ordinate is the fractional saturation of haemoglobin by oxygen and the abscissa the partial pressure of oxygen (p_{O_2}) in mm Hg. The standard errors of the mean p_{O_2} ($n = 6$) for 50% saturation are represented by horizontal bars. Intra-erythrocyte ATP/Hb ratios for the three phenotypes are presented in the inset. ATP was determined by the firefly luciferase assay[11]. *Fundulus* haemoglobin concentrations were determined as described previously[5]. The values for ATP/Hb are: *a*, $LDH\text{-}B^aB^a = 1.27 \pm 0.08$ ($n = 6$); *b*, $LDH\text{-}B^aB^b = 1.83 \pm 0.11$ ($n = 5$); *c*, $LDH\text{-}B^bB^b = 2.00 \pm 0.06$ ($n = 5$). All animals were acclimated to laboratory conditions for 30 d before assays. Temperature, 20.5°C, *p*H 7.4.

between LDH and the fish's external environment through the physiological role of haemoglobin at the organism–environment interface.

There are three major electrophoretically distinguishable phenotypes of the heart-type LDH (the *LDH-B* locus) in *F. heteroclitus*[7,8]. The polymorphism is due to two co-dominant alleles which exhibit a dramatic north–south cline in gene frequency along the Atlantic coast of the US[9,10]. The two common *LDH-B* homozygous phenotypes yield fast ($LDH\text{-}B^aB^a$) and slow ($LDH\text{-}B^bB^b$) bands on electrophoresis, whereas the heterozygote phenotype ($LDH\text{-}B^aB^b$) gives the classic five-banded pattern[8]. The *B* locus is the only LDH expressed in the red blood cells of this fish[8]. When intra-erythrocyte ATP levels (expressed as molar ratios of ATP/Hb) are compared for individuals of different *LDH-B* phenotype, a significant association ($F_{[2,13]} = 20.58$, $P < 0.001$; index of association $\omega^2 = 0.76$) is found (see inset in Fig. 1).

ATP is the major organic phosphate in the red blood cells of *F. heteroclitus*[5]. Its role as an allosteric modifier of fish haemoglobins is similar to that of 2,3-diphosphoglycerate in mammalian red blood cells, in that it decreases the affinity of haemoglobin for oxygen[5]. A decrease in haemoglobin–oxygen affinity is characterised by an increase in the partial pressure of oxygen at which one-half of the haemoglobin is saturated with oxygen (the P_{50}). As the intra-erythrocyte ATP/Hb ratio is different for each of the *LDH-B* phenotypes, we expected to find differences in haemoglobin–oxygen affinity also. In agreement with this expectation (Fig. 1), $LDH\text{-}B^aB^a$ homozygotes with the lowest ATP/Hb ratio have the highest oxygen affinity and $LDH\text{-}B^bB^b$ homozygotes with the highest ATP/Hb value have the lowest oxygen affinity. At the same partial pressure ($p_{O_2} = 10$ mm Hg) the haemoglobin from $LDH\text{-}B^aB^a$ fish is 96% saturated with oxygen, whereas that of $LDH\text{-}B^bB^b$ individuals is only 80% saturated. Such differences in oxygen loading would be exaggerated *in vivo* when blood *p*H is reduced following an increase in temperature and/or anaerobic metabolism[5].

Our work on the haemoglobin components of *F. heteroclitus* indicates that the shift in oxygen equilibria does not result from a difference in the distribution of the haemoglobin components between the *LDH-B* phenotypes, as all individuals express the same complement of components. In addition, each isohaemoglobin responds similarly to the changes in *p*H, temperature and ATP concentration[5]. Therefore, the differences in intra-erythrocyte ATP concentrations reported here must be either the result of: (1) functional differences between the LDH-B allozymes which affect cellular ATP levels, or (2) the regulation of ATP levels by other enzymes which are genetically linked to the *LDH-B* locus. Studies are now underway to answer this question. Also, selection experiments are in progress to determine the feasibility of oxygen and *p*H as selective agents for the *LDH-B* phenotypes of *F. heteroclitus*.

Whatever the molecular basis for these ATP differences, it is clear that the $LDH\text{-}B^aB^a$ phenotype has a lower intra-erythrocyte ATP concentration than $LDH\text{-}B^bB^b$ individuals and as a consequence, a higher haemoglobin–oxygen affinity (Fig. 1). Fish with the $LDH\text{-}B^aB^a$ phenotype might therefore have a selective advantage when competing with individuals of the other two phenotypes in a low oxygen environment. Final resolution of this phenomenon may help resolve the controversy between exponents of the 'selectionist' and 'neutralist' evolutionary theories concerning the maintenance of protein polymorphisms in natural populations.

Immunoprecipitation of protein kinase activity from adenovirus 5-infected cells using antiserum directed against tumour antigens

THE function of transformation proteins coded for by RNA- and DNA-containing tumour viruses is a major question in oncology. A large number of diverse alterations are produced in cells following viral transformation, and such changes are thought to be the result of the action of one or a very few viral gene products. Until recently, very little was known concerning the mechanism of action of such transforming proteins.

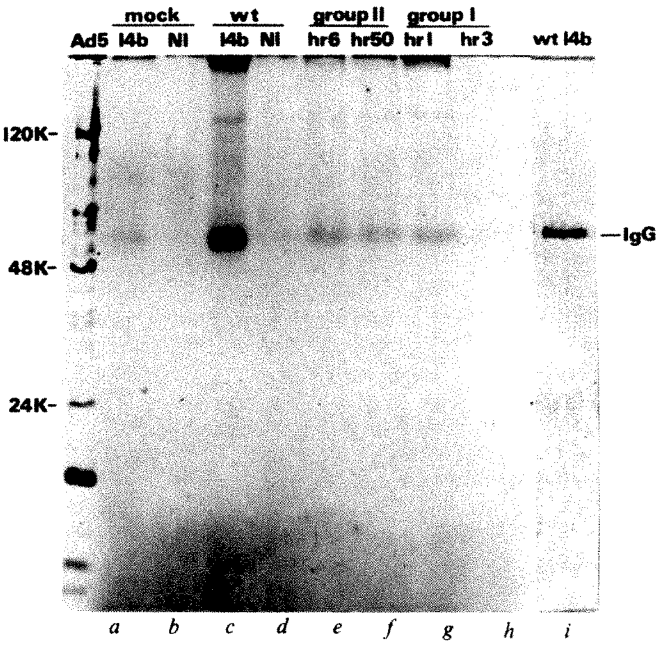

Fig. 1 *In vitro* phosphorylation of immunoprecipitates from Ad 5- and mock-infected cells. Proliferating KB cells were infected with Ad 5 (50 plaque-forming units per cell) or were mock infected. At 9 h post-infection, cytoplasmic extracts were prepared and these were immunoprecipitated using a method similar to that of Schaffhausen *et al.*[9]. Cells were scraped off 100-mm Petri dishes, washed twice with cold phosphate-buffered saline, rinsed with cold buffer containing 20 mM Tris (*p*H 8.0), 137 mM NaCl, 1 mM CaCl$_2$, 0.5 mM MgCl$_2$ and 10% glycerol (v/v), and then lysed in the same rinsing buffer containing 1% NP40 (v/v). After incubating the cells at 4 °C for 20 min, nuclei were removed by centrifugation at 2,000 r.p.m. for 10 min in an IEC centrifuge. To the supernatant from an equivalent of 2×10^7 cells was added 10 µl of 14b antiserum or nonimmune serum and 40 µl of protein A–Sepharose CL-4B (Pharmacia) which had been equilibrated in rinsing buffer containing NP40 and glycerol. After 2 h in the cold with constant mixing, the Sepharose beads with bound antibody were pelleted by low speed centrifugation (400 r.p.m. for 30 s in an IEC centrifuge), and then washed 3 times with 100 mM Tris (*p*H 8.0) containing 200 mM LiCl and 0.1% 2-mercaptoethanol (v/v), and once with 1 mM Tris (*p*H 7.0) containing 150 mM NaCl. The final pellet was resuspended in 50 µl of 40 mM sodium acetate (*p*H 6.0) containing 10 mM MgCl$_2$ and 7.5 µM [γ-^{32}P] ATP (specific activity 250 Ci mmol^{-1}; NEN), and the mixture was incubated for 10 min at 37 °C. The reaction was terminated by the addition of 100 µl of standard double-strength SDS sample buffer[12] and the immune complexes were eluted from the Sepharose beads by boiling for 2–3 min. The beads were removed by low-speed centrifugation and equal volumes (25 µl) of supernatant were then analysed by SDS-PAGE using a 16% polyacrylamide slab gel. The gel was stained with Coomassie brilliant blue, dried, and an autoradiograph was prepared using Kodak RP X-Omat film. Mock-infected cells treated with 14b (*a*) or nonimmune (*b*) serum. Wild-type Ad 5-infected cells treated with 14b (*c*) or nonimmune (*d*) serum. Cells infected with Ad 5 group II host range mutants hr 6 (*e*) and hr 50 (*f*) treated with 14b antiserum. Cells infected with Ad 5 group I host range mutants hr 1 (*g*) and hr 3 (*h*) treated with 14b antiserum. Coomassie blue-stained gel of wild-type-infected cells treated with 14b antiserum (*i*). ^{35}S-methionine-labelled Ad 5 virion proteins are included as molecular weight markers.

However, studies carried out by Collett and Erikson with the RNA tumour virus Rous sarcoma virus (RSV) suggested that the RSV transforming protein, src, either possesses or is associated with protein kinase activity[1]. Using antiserum directed against virus-coded proteins, it was found that phosphorylation of the heavy chain of the antibody occurred when immunoprecipitates containing src protein were incubated with [γ-^{32}P]ATP. No such protein kinase activity was observed in immunoprecipitates using uninfected cell extracts, extracts from cells infected with transformation-defective virus, or control nonimmune serum. These data suggest that alterations in protein phosphorylation may regulate RSV transformation. This concept is quite appealing, as protein phosphorylation is already known to have an important regulatory role in several cellular processes[2–4]. We show here that antiserum directed against tumour antigens of a DNA virus, human adenovirus type 5 (Ad 5), will also immunoprecipitate protein kinase activity. Further, immunoprecipitates from cells infected with transformation-defective host range mutants of Ad 5 contain reduced levels of protein kinase activity.

We have used an approach similar to that of Collett and Erikson to determine if the transforming gene products of Ad 5 possess protein kinase activity. Antiserum against viral transformation proteins was obtained from hamsters bearing tumours induced by Ad 5-transformed hamster cells. The transformed cells, designated 14b, contain 40% of the left end of the Ad 5 DNA molecule[5] and transcribe 7% of the genome near the left end[6]. This region of the viral DNA molecule is necessary and sufficient for oncogenic transformation[7,8]. Thus, antiserum prepared against 14b cells should contain antibodies directed against only the transforming proteins of Ad 5.

Cytoplasmic extracts were prepared from Ad 5-infected and mock-infected human KB cells and these were immunoprecipitated with immune or control nonimmune serum, using essentially the procedure of Schaffhausen *et al.*[9]. Washed immune complexes were then incubated in the presence of [γ-^{32}P]ATP and the samples were analysed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE). Studies were also carried out using extracts from KB cells infected with host range mutants of Ad 5. These mutants have been shown to fall into two complementation groups, I and II (ref. 10), both of which are transformation defective[11].

Figure 1 shows an autoradiograph of immunoprecipitates incubated with [γ-^{32}P]ATP. With wild-type Ad 5-infected cell extracts and immune serum (Fig. 1*c*), a major ^{32}P-labelled species was observed which co-migrated with the heavy chain of IgG (see Fig. 1*i*). Several minor labelled bands of higher molecular weight were also observed, and additional labelled species appeared with prolonged exposure of the gel. Incorporation into the light chain of the antibody was not detected. Little incorporation was observed with extracts from wild-type-infected cells precipitated by nonimmune serum (Fig. 1*d*), or with extracts from mock-infected cells (Fig. 1*a*, *b*). Counts on bands excised from the gel indicated that the amount of ^{32}P incorporated into the heavy chain of IgG was 14 times greater with infected cell extracts and immune serum than with controls. Similar experiments with the host range mutants hr 6 and hr 50 of group II (Fig. 1*e*, *f*, respectively), and hr 1 and hr 3 of group I (Fig. 1*g*, *h*, respectively) gave levels of incorporation into the heavy chain of IgG which were reduced compared to wild-type Ad 5 (30–60% of wild type).

With immunoprecipitates from wild-type-infected cell extracts, the reaction was very rapid, maximum incorporation into IgG occurring within 1 min at 37 °C. No incorporation of ^{32}P into IgG was observed when the immune complex was heated at 100 °C for 2 min before incubation with [γ-^{32}P]ATP.

As high levels of endogenous protein kinase activity exist in all mammalian cells, the activity found in immunoprecipitates from Ad 5-infected cells could be due to nonspecific entrapment during formation of the antigen–antibody complex. To exclude this possibility, an unrelated antigen–antibody complex (human IgG and sheep anti-human IgG) was formed in an extract from Ad 5-infected cells. The complex was immunoprecipitated and incubated with [γ-^{32}P]ATP. No incorporation of ^{32}P into IgG was observed in these conditions (data not shown). Thus, it is unlikely that the Ad 5-associated protein kinase activity resulted from entrapment of cellular enzymes, as the amount of antigen–antibody complex in this control study was far in excess of that obtained using infected cell extracts and immune serum. Results from another experiment suggest that the protein kinase activity found in immunoprecipitates from infected as opposed to control cell extracts was not due to the presence of vastly different levels of total enzyme activity in the two preparations: cytoplasmic extracts (containing equal amounts of protein) were incubated with [γ-^{32}P]ATP in a reaction mixture similar to that described in the legend to Fig. 1 and the amount of protein kinase activity was measured using endogenous substrates (as described in ref. 12). Ad 5-infected cells contained only 1.4 times more total activity than uninfected cells.

Our results are similar to those obtained with RSV[1]. The data suggest that an Ad 5 transformation-specific protein either is a protein kinase or is associated with one. Whether this activity is due to a virus-coded or virus-induced cellular enzyme is at present not clear. However, because the antiserum was raised in hamsters using transformed hamster cells and the immunoprecipitation experiments were carried out with infected human cell extracts, it seems more likely that it is a virus-coded function. The immune antiserum binds specifically to at least two Ad 5-induced polypeptides, of molecular weights of 58,000 and 10,500 (refs 13, 14), as well as other minor species (N.J.L., unpublished). Localisation of protein kinase activity to a specific polypeptide will require further studies. With transformation-defective host range mutants, enzyme activity was reduced, suggesting that these mutants are at least partly deficient in this function. Furthermore, some of the activity obtained with the mutants may be due to leakiness caused by the high multiplicity of infection.

It is now apparent that protein kinase activity is associated with the transforming proteins of both an RNA and a DNA tumour virus and thus alterations in protein phosphorylation may be a general mechanism by which all tumour viruses induce cellular transformation.

We thank W. E. Rawls for discussions. The 14b cells were obtained from J. F. Williams. This work was supported through grants from the NCI, the MRC and the NRC of Canada. N. J. L. is a research student and F.L.G. and P.E.B. are research scholars of the NCI of Canada.

Kinetics of *in vitro* reconstitution of oligomeric enzymes by cross-linking

THE reconstitution of oligomeric enzymes from their denatured state is a consecutive process consisting of folding and association steps. In the case of multimeric enzymes the pathway of reassociation and its correlation with the occurrence of enzymatic activity is an open question. The combined use of cross-linking and SDS-polyacrylamide gel electrophoresis allows the assembly of multimeric enzymes to be followed quantitatively.

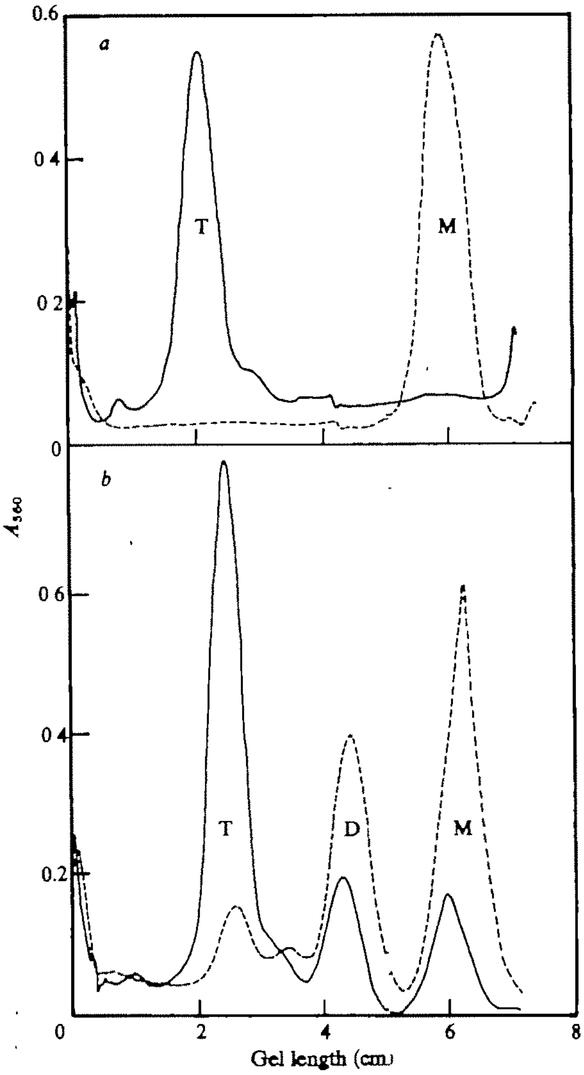

Fig. 1 SDS-polyacrylamide gel electrophoresis of cross-linked LDH-M_4. Cross-linking by 2 min incubation in 0.3–0.4 mM glutaraldehyde, 20 °C, was stopped by addition of 15–25 μM SDS; unreacted bifunctional reagent was inactivated by 3–4 mM hydrazine The solutions were heated for 10 min (100 °C) and subsequently stored for 2 h at 20 °C. For concentrating, the protein solutions were dialysed for 24 h against 20% polyethyleneglycol before electrophoresis (5% polyacrylamide gel containing 0.15% SDS). The gels were stained for 2 h with 0.1% Coomassie blue R 250 in 50% trichloroacetic acid, and destained in 7% acetic acid plus 5% methanol. 0.2 M phosphate buffer, *p*H 7.6, plus 5 mM EDTA was used throughout. The gels were scanned at 560 nm. Correlation of the bands to the tetrameric (T), dimeric (D) and monomeric (M) fractions of LDH was achieved by calibration with proteins of defined molecular weight (dimeric and monomeric human serum albumin, monomeric LDH and lysozyme). *a*, Cross-linking of native tetramers (solid line) and SDS-denatured monomers (dashed line); monomer concentration, 81 nM. *b*, Cross-linking of reactivating LDH after acid dissociation at *p*H 2.3. Reactivation at 20 °C by dilution at *p*H 7.6, final monomer concentration, 343 nM. Cross-linking after 210 s (dashed line) and 1 h (solid line) of reactivation and reassociation.

We report here that by applying this technique to a study of lactic dehydrogenase from pig muscle, we have shown that tetramer formation parallels reactivation of the enzyme.

Nascent polypeptide chains fold spontaneously to defined three-dimensional structures, without additional information beyond the specific amino acid sequence of the given protein and its aqueous environment. In addition, protein molecules above a critical chain length tend to associate to form stoichiometrically and geometrically well defined quaternary structures. In this

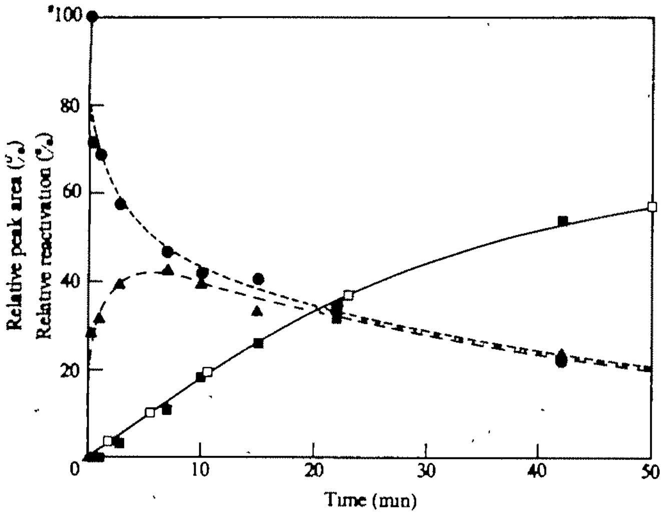

Fig. 2 Determination of the kinetics of reassociation of LDH-M_4 by cross-linking. Experimental details as described in Fig. 1. Reassociation (20 °C) at 170 nM monomer concentration analysed by drawing aliquots at defined times and fixation of the association products by cross-linking. Percentage of monomers (●), dimers (▲) and tetramers (■) defined by the respective peak areas relative to their total amount. Reactivation (□), as determined by testing aliquots at defined times in standard test conditions, was calculated relative to the final extent of reactivation (75% after 6 d).

connection, folding and association can be considered as the final stages of protein biosynthesis. The timing of the two processes must be coordinated because the correct assembly of subunits requires proper folding to defined three-dimensional structures. In this sense the primary function of 'folded monomers' is self-assembly[1].

For single-chain proteins a variety of experimental approaches has allowed the identification of intermediates along the folding pathway[2]. These *in vitro* studies have mostly been aimed at the prediction of three-dimensional structures from the amino acid sequences and the elucidation of the mechanisms dominating the folding process *in vivo*[2–4].

In multi-chain proteins, folding is inherently correlated with the association of subunits. Besides the folding of the isolated polypeptide chains, additional transconformation reactions occur after the association of the native quaternary structure has taken place. Recent analyses of the reactivation kinetics of several oligomeric enzymes have demonstrated that the reassociation process is a prerequisite for conformational transitions leading to the complete restoration of the native enzymatic properties[5–8]. The corresponding reactivation relaxations obey a simple kinetic mechanism consisting of two consecutive first order and second order reactions[6,8,9]. The assignment of the respective rate-limiting steps to certain elementary processes in the overall transconformation–association reaction has not been feasible so far. It would require the quantitative determination of the kinetics of association, for example, by light scattering measurements, which is not practicable because of the unfavourable signal-to-noise ratio at low enzyme concentrations and the difficulties connected with a quantitative population analysis.

Therefore, we developed a method of analysing the association kinetics of oligomeric enzymes by cross-linking the refolding subunits with a bifunctional reagent (glutaraldehyde), and subsequent separation of the various association products by SDS-gel electrophoresis. The method allows the detection and quantitative evaluation of intermediates of association even at very low enzyme concentrations. The kinetics of formation and disappearance of these intermediates can be analysed by taking aliquots of the enzyme solution at defined times during the process of reconstitution. Parallel measurements of the regained enzymatic activity in identical conditions were carried out to correlate the kinetics of reassociation and reactivation. The determination of the kinetic constants of the latter reaction may reveal whether or not subunits as intermediates of reconstitution represent catalytically active entities.

We used lactic dehydrogenase (LDH-M_4) from pig skeletal muscle (Boehringer). The different isoenzymes of mammalian LDH are composed of four subunits, the structural and catalytic properties of which have been investigated in great detail[10]. The hydrodynamic and spectral properties of the dissociated, inactive and partially unfolded monomers, present at *p*H 2.3, have been described previously[11,12]. After renaturation, the reactivated tetramers were found to be indistinguishable from the native isoenzymes by testing for a variety of physicochemical and enzymatic parameters[5,11,12].

The reactivation of both isoenzymes (LDH-M_4 and H_4 from pig) was found to be dominated by second order reactions; slightly sigmoidal relaxations (especially for LDH-H_4) suggest, however, that first order reactions are involved to a certain extent[8,11–13]. The overall process can be quantitatively described as a consecutive uni-bimolecular reaction sequence. For both isoenzymes, the respective rates of reactivation are not influenced by their coenzyme, NADH or NAD^+ (refs 5,14).

In the present experiments, LDH-M_4, after denaturation at *p*H 2.3, was renatured at *p*H 7.6 in the absence of cofactors or substrates. At specified times after dilution, aliquots were analysed with respect to their particle distribution and the regeneration of enzymatic activity. To ensure fast and quantitative intramolecular cross-linking of associated particles, a high molar excess (10^5–10^7) of glutaraldehyde was used. To prevent intermolecular cross-linking, the reaction was stopped after a constant reaction time of 2 min by addition of 5% SDS and inactivation of excess glutaraldehyde by the addition of hydrazine[15].

As Fig. 1*a* shows, optimum conditions gave 100% cross-linking and fixation of native enzyme in its tetrameric state, whereas cross-linking of the SDS-dissociated enzyme yielded only monomers. No high molecular weight products were formed by inter-molecular cross bridges in either of the blank experiments. Therefore, cross-linking and subsequent SDS electrophoresis can be used to determine relative amounts of the different states of association present at various times during reassociation (Fig. 1*b*). The kinetic traces for the decrease of the concentration of monomers and the formation of dimers and tetramers show that within the range of experimental error, tetramer formation clearly parallels the time course of reactivation (Fig. 2).

The identification of monomers, dimers and tetramers during reassociation (Figs 1*b*, 2) shows that at least two reactions are rate limiting in the overall process of reconstitution. Considering the fact that the reactivation kinetics for LDH-M_4 (apart from an insignificant contribution of rapid first order transconformation reactions) can be described by a single second order rate constant[8,11], one may exclude the possibility that two consecutive bimolecular reactions are rate determining for reactivation and tetramer formation. This means that only one of the reactions which is rate limiting for the formation of dimers from monomers, or of tetramers from dimers, is determined by an association process; the other must be of first order[16].

From our data it is not possible to show if the formation of dimers or tetramers is governed by the association reaction. This can only be clarified by analysing the formation of dimers and tetramers at various initial concentrations of monomers. That reactivation and tetramer formation take place together clearly shows that those dimers which accumulate during reassociation do not possess appreciable catalytic activity. This does not rule out the possibility that active dimers occur as intermediates of reactivation. Whether a kinetic model consisting of two consecutive unimolecular and bimolecular reactions is sufficient to describe the observed patterns of dimer and tetramer formation, or whether more sophisticated models, including rapid equilibria, are necessary, cannot yet be decided.

with the Canalco HSG Chamber for Horizontal Slab Gel Electrophoresis in agarose or polyacrylamide gel. Designed expressly for DNA research, the horizontal-format apparatus features a removable gel tray which provides support for low-mechanical-strength gels (0.18% agarose) during electrophoresis, staining, and photography. Gels are 19.5 cm wide by 40 cm long—long enough to resolve very complex mixtures in a single run. The chamber is capable of simultaneous analysis of 96 specimens; and it may be used preparatively, with gels up to 2.5 cm thick.

The Canalco HSG Chamber has numerous other features designed to help you perform electrophoresis effectively, including: Provision for buffer recirculation • Reusable gel wicks • Temperature control (up to +60°C for heat denaturation) • Safety interlock • Optional UV-transparent gel tray (for use with ethidium bromide or other fluorescent stains)

Formation of a new fluorophore on irradiation of carboxymethylated D-glyceraldehyde-3-phosphate dehydrogenase

BECAUSE of its physiological importance, allosteric properties and ready availability, D-glyceraldehyde-3-phosphate dehydrogenase (G3PDH) is one of the most thoroughly studied of the dehydrogenases. We report here a study of the ligand binding properties of G3PDH. We observed that when active site carboxymethylated G3PDH was irradiated with near ultraviolet light in the presence of NAD^+, a new fluorophore was formed.

A six-times recrystallised G3PDH from rabbit muscle was modified with iodoacetate until less than 5% of the original activity remained. The reaction mixture was then passed through a Sephadex G-50 column to remove excess iodoacetate. Determination of the sulphhydryl groups present before and after iodoacetate treatment with 5,5′-dithio-bis(2-nitrobenzoic acid) showed that only one sulphhydryl group per subunit was modified—this is presumably Cys-149 at the active site[1]. When the active site-carboxymethylated enzyme was irradiated in the presence of excess NAD^+ with a 150-W xenon lamp for 6 min, a new fluorophore was formed. The excitation spectrum of the new fluorophore shows peaks at 290 and 325 nm whereas the emission maximum is at 410 nm (Fig. 1). The photochemical reaction leading to the formation of the new fluorophore appears to be quite specific. Neither the holoenzyme nor the iodoacetamide- or sodium tetrathionate-modified enzyme can form the new fluorophore. At much higher concentrations, $NADP^+$ and NMN^+ can replace NAD^+ to form new fluorophores with emission maxima at 410 and 385 nm respectively, whereas AMP, ATP or ADPR are completely ineffective. These results suggest that the nicotinamide ring and the carboxyl group introduced at the active site Cys-149 are involved in the formation of the new fluorophore.

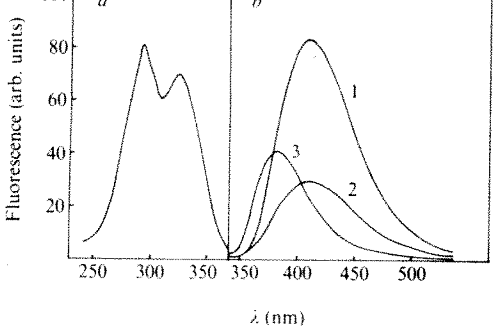

Fig. 1 Excitation and emission spectra of the fluorophores formed on irradiation of carboxymethylated G3PDH with nicotinamide nucleotides. *a*, Excitation spectrum of the fluorophore formed with NAD^+. *b*, Emission spectra of the fluorophores formed with NAD^+(1), $NADP^+$(2) and NMN^+(3). Enzyme concentration in all cases, 3 μM.

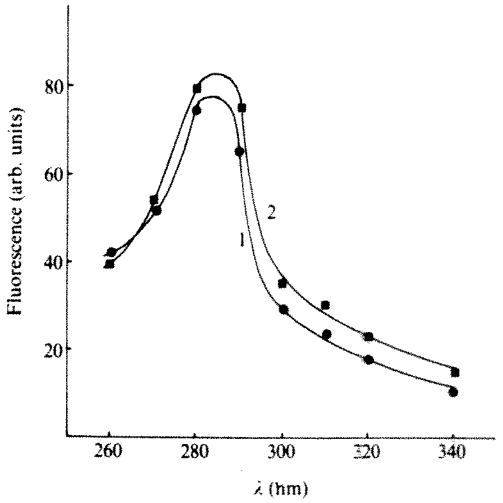

Fig. 2 Photochemical action spectrum for the formation of the NAD^+ fluorophore. Portions of carboxymethylated G3PDH, 3 μM and NAD^+, 33 μM in 0.1 M phosphate buffer, *p*H 6.7 were directly irradiated with lights of different wavelengths through the excitation monochromator of a MPF-4 spectrofluorometer at a slit width of 10 nm for 20 min each to give curve 1. The excitation spectrum of a concentrated rhodamine B solution was then scanned. The fluorescence intensity of this solution at each wavelength of excitation is directly proportional to the quantum input at this wavelength and can be used for the correction of curve 1 to give the true photochemical action spectrum for the formation of the new fluorophore (curve 2).

The new fluorophore is tightly bound to the enzyme protein as shown by the following experiments. Treatment with excess activated charcoal removed all the NAD^+ added in excess and raised the ratio of A_{280} to A_{260} to 1.4–1.5, but failed to remove the fluorophore from the enzyme protein. After passage through a Sephadex G-50 column, only the protein fraction was fluorescent, the NAD^+ fraction showed no significant fluorescence. Furthermore, ethanol at concentrations greater than 60% also precipitated the enzyme protein together with the fluorophore.

When carboxymethylated G3PDH was irradiated with monochromatic light in the presence of NAD^+, the photochemical action spectrum obtained (Fig. 2) showed a broad maximum in the 280–290 nm region. Absorption by tyrosine residues decreases sharply at wavelengths longer than 280 nm, so our findings implicate strongly the excitation of tryptophan residues in the formation of the new fluorophore.

With excess NAD^+ removed by charcoal adsorption, the irradiated enzyme shows a broad absorption band at 325 nm due to the new fluorophore. This overlaps with the 295 nm excited protein fluorescence at 335 nm due to tryptophan residues. During the course of irradiation, with the gradual appearance of the new fluorescence band at 410 nm, the tryptophan fluorescence was quenched as shown in Fig. 3. Determinations with *p*-*N*-dimethylaminobenzaldehyde showed that no destruction of tryptophan residues had occurred. The quenching of tryptophan fluorescence is, therefore, due to a radiationless energy transfer from tryptophan to the new fluorophore. As both the A_{280}/A_{260} ratio and the amino acid composition of the irradiated enzyme seem to suggest that the photochemical formation of the new fluorophore may also be a 'half-of-the-sites' reaction,

0028–0836/79/0277—0245$01.00

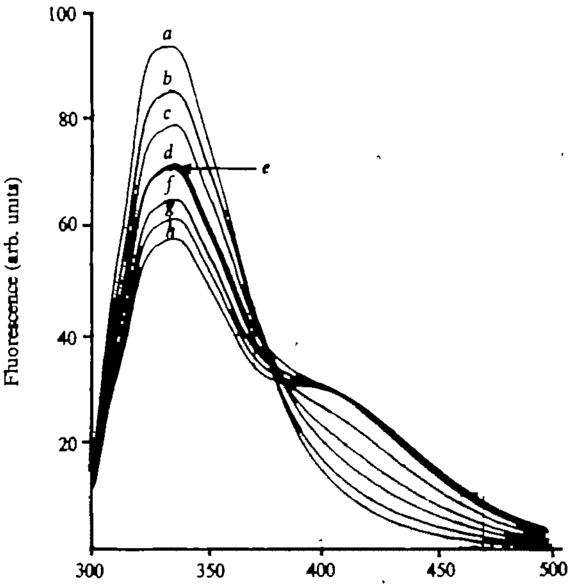

Fig. 3 Quenching of tryptophan fluorescence during the formation of the new fluorophore. Carboxymethylated G3PDH, 3 μM and NAD$^+$ 33 μM in 0.1 M phosphate buffer, *p*H 6.7 was irradiated in the MPF-4 spectrofluorometer with an exciting light of 290 nm and a slit width of 20 nm. The emission spectra with the exciting wavelength also at 290 nm were scanned at *a*, 0, *b*, 1.5, *c*, 3; *d*, 6; *e*, 9; *f*, 12; *g*, 15 and *h*, 20 min.

this energy transfer involves probably only two of the four subunits. Calculations based on the Förster equation with the orientation factor K^2 taken as 2/3 give a distance between tryptophan and the new fluorophore of 15.79 Å. As each subunit of the rabbit muscle enzyme has three tryptophan residues, this probably represents a weighted average value of the distances between the three tryptophan residues to the new fluorophore. This value can be compared with the results of X-ray crystallographic analysis of the lobster[3] and bacterial[4] enzymes.

The formation and the fluorescence of the new fluorophore were found to be sensitive to conformational changes of the enzyme protein. Sodium dodecylsulphate (SDS) at a weight ratio of 1:1 with the enzyme led to a 50% decrease in the fluorescence intensity at 410 nm. However, even more marked was the effect of SDS on the formation of the new fluorophore. As shown in Fig. 4, the presence of SDS at a weight ratio of 0.5 during irradiation was enough to decrease the 410 nm fluorescence formed by 75%. It has been reported[5] that SDS at a weight ratio to G3PDH of 0.5 loosened its tertiary structure and at a ratio of 1 dissociated this enzyme. Our own studies by difference spectroscopy and protein fluorescence also showed that with increasing SDS to enzyme ratios, the internal tryptophan and tyrosine residues of G3PDH were gradually exposed. The great sensitivity of the formation of the new fluorophore seems to suggest that the photochemical reaction leading to its formation has strict requirements on the spatial relationship of excited tryptophan residue(s), the carboxymethyl group introduced at Cys-149 and the nicotinamide ring.

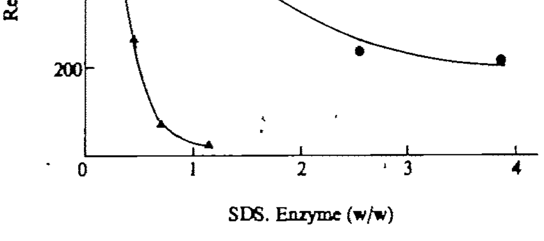

Fig. 4 Effect of sodium dodecylsulphate on the formation and intensity of the new fluorophore. Curve 1 shows the effect of SDS present during irradiation on the formation of the 410 nm fluorophore. Curve 2 shows the effect of SDS added after the formation of the new fluorophore on its fluorescence intensity. Relative fluorescence intensity plotted against the weight ratio of SDS to the enzyme. Final concentration of the enzyme was 2 μM with 22 μM NAD$^+$ in 0.1 M phosphate buffer, *p*H 6.7.

Further studies are needed to establish the chemical nature of the new fluorophore. At present, we can say that it is tightly, probably covalently, bound to the enzyme protein and its spectral and fluorescence properties closely resemble a series of addition compounds[6] of NAD$^+$ including NADH.

In spite of some earlier suggestions[7,8], very little is known about the role of tryptophan residues in G3PDH. Our results demonstrate the close relationship between tryptophan, Cys-149 and the nicotinamide ring and suggests the need for close examination of this problem.

Further details of this work will be published elsewhere[9].

Errata

In the letter 'Photographic amplification of faint astronomical images' by D. F. Malin, *Nature* **276**, 591–593, the figures have been transposed. Figure 1 is shown above Fig. 2 legend and Fig. 2 above Fig. 1 legend.

In the article 'Olivine fractionation equations for basaltic and ultrabasic liquids' by T. H. Pearce, *Nature* **276**, 771–774, equation (12) should read:

$$\log\left(\frac{y}{z}\right)=K\log\left(\frac{x}{z}\right)+\log\left(\frac{y_0}{x_0}\times\frac{z_0^{k-1}}{x_0^{k-1}}\right)$$

equation (14) should read:

$$\log\left(\frac{\mathrm{FeO}}{\mathrm{Al_2O_3}}\right)_{\mathrm{l}}=K\log\left(\frac{\mathrm{MgO}}{\mathrm{Al_2O_3}}\right)_{\mathrm{l}}+\log\left(\frac{\mathrm{FeO}}{\mathrm{MgO}}\right)_{\mathrm{P}}\times\left(\frac{\mathrm{Al_2O_3}}{\mathrm{MgO}}\right)_{\mathrm{P}}^{k-1}$$

In the article 'Analysis of ^{36}Cl in environmental water samples using an electrostatic accelerator' by D. Elmore *et al.*, *Nature* **277**, 22–25, the last sentence in the summary should read: 'For each sample less than 70 mg of AgCl were used, requiring 1–5 litres of water.' Line 19 on page 23 should read 'with mass spectrometers lies in the difficulty of separating...' In line 41 for 'from' read 'with'. In line 47 for ref. 18 read ref. 17. In Table 1 the units in the last three columns should read: (d.p.m. per kg Cl); (mg l^{-1}); (×10^{-6}, atoms l^{-1}). An extra line should be added to the table:

Groundwater, deep well near Tucson, AZ

101	990	4	320±50	24	10	53

In line 31 in the right column for 'neutral' read 'natural' and in line 54, for 100-mg read 20-mg.

Aims and Scope
Commencing publication early in 1979, this journal will publish material within the general field of the immunology of reproduction. This will encompass clinical and experimental investigation of immunological factors involved in normal and pathological reproductive processes in both male and female, as well as the application of immunological techniques for the analysis of embryonic development and for the regulation of fertility.
A rigorous editorial policy will ensure that only those papers of high scientific quality and originality are published, as indicated in the following list of contents to be included in the first issue:-

E.J. Jenkinson and R.F. Searle Ia antigen expression on the developing mouse embryo and placenta

P.N. Goodfellow, J.R. Levinson, R.J. Gable and H.O. McDevitt Analysis of anti-sperm sera for T/t locus-specific antibody

P.W. Slobodian, G.A. Carlson and T.G. Wegmann The processing of T lymphocytes by the gut of the suckling neonate

C. Pavia, P.K. Siiteri, J.D. Perlman and D.P. Stites Suppression of murine allogeneic cell interactions by sex hormones

J.K. Kelly and H. Fox The local immunological defence system of the human endometrium

D.B. Morton and P.A. McAnulty The effect on fertility of immunizing female sheep with ram sperm acrosin and hyaluronidase.

PLENUM &

MATHEMATICS

Applied Mathematics
An Intellectual Orientation
by **Francis J. Murray**

This unusually practical text provides a framework for applying mathematics to actual problems in technological systems and scientific research, elucidating many of the practical demands made upon the "pure" mathematician and suggesting appropriate responses. *Mathematical Concepts and Methods in Science and Engineering, Volume 12.* 239 pp., illus., 1978, $35.40/£18.59

Integral Transforms in Science and Engineering
by **Kurt Bernardo Wolf**

Provides a systematic, detailed examination of the theoretical and applied aspects of finite transforms, function vector spaces, Fourier and related integral transforms, canonical transformations in quantum mechanics, hyperdifferential operator realizations for the transforms, and similarity groups for a class of differential equations. *Mathematical Concepts and Methods in Science and Engineering, Volume 11.* approx. 475 pp., illus., 1978, $39.00/£20.48

PHYSICS

Understanding the Fundamental Constituents of Matter
edited by **Antonino Zichichi**

Examines studies describing finite size particles, the discovery of new particles in e^+e^- and neutrino interactions, and recent progress toward mastering strong interactions. *The Subnuclear Series, Volume 14.* 926 pp., 1978, $90.00/£47.25

Cosmic Rays in the Stratosphere and in Near Space
edited by **N. G. Basov**
Translated from Russian by
James S. Wood

This volume examines intensities of various components of cosmic rays, fluxes of assorted particle species in the stratosphere and in near space, theoretical and empirical laws, and correlations between cosmic rays and solar activity. *The Lebedev Physics Institute Series, Volume 88.* 188 pp., illus., 1978, $47.40/£24.89

CHEMISTRY

Ion-Selective Electrodes in Analytical Chemistry
Volume 1
edited by **Henry Freiser**

Contents: Theory and principles of membrane electrodes. Precipitate-based ion-selective electrodes. Ion-selective electrodes based on neutral carriers. Poly(vinyl chloride) matrix membrane ion-selective electrodes. Sources of error in ion-selective electrode potentiometry. Applications of ion-selective electrodes. Index.

A volume in *Modern Analytical Chemistry* 454 pp., 1978, $51.00/£26.78

Quantum Electrochemistry
by **J. O'M. Bockris**
and **S. U. M. Khan**

Contents: Electric double layers at metals. Electrode kinetics. Quanta and surfaces. The time-dependent perturbation theory. Long-range radiationless energy transfer in condensed media. Mechanisms of activation. The continuum theory. Interfacial electron tunnelling. Proton transfer in solution. Proton transfer at interfaces. The hydrated electron. Photo-electrochemical kinetics. Quantum electrode kinetics.

approx. 510 pp., illus., 1979, $59.40/£31.19

TECHNOLOGY

High-Pressure Science and Technology
edited by **K. D. Timmerhaus**
and **M. S. Barber**

Reflecting the breadth of current research on high-pressure theory, design, and application, these volumes examine such areas as energy resources, high-pressure kinetics, phase transition on both electronic and lattice levels, and equations of state, as well as numerous other areas of research.

Volume 1: Physical Properties and Material Synthesis
approx. 1,055 pp., 1979, $90.00/£47.25

Volume 2: Applications and Mechanical Properties
approx. 1,055 pp., 1979, $90.00/£47.25
two-volume set: $168.00/£88.20

Structures
Or Why Things Don't Fall Down
by **J. E. Gordon**

This fascinating, witty introduction to engineering thought and history examines fundamental interactions among energy, materials, and design in such diverse "structures" as catapults, chariots, feathers, clothing, sailing rigs, kangaroos, suspension bridges, pterodactyls, and the human skeleton and musculature. 395 pp., illus., 1978, $21.54/£11.31

EARTH SCIENCE

Advances in Oceanography
edited by **Henry Charnock**
and **Sir George Beacon**

Delineates the problems and potential of modern oceanography and covers a wide range of topics, including a systems analysis of the Baltic, chemistry and climate of surface waters, ocean circulation and its effects on marine life, and the resources of the sea. 364 pp., 1978, $47.40/£24.89

Ocean Wave Climate
edited by **Marshall D. Earle**
and **Alexander Malahoff**

Discusses ocean engineering and scientific uses of wave data, existing wave monitoring programs, and measurement techniques. Special emphasis is placed on recent wave data applications and advanced measurement systems that may be utilized routinely in the future. *Marine Science, Volume 8.* approx. 400 pp., 1979, $43.20/£22.68

BIOLOGY

The Biology of Aging
edited by **John A. Behnke**
Caleb E. Finch
and **Gairdner B. Moment**

Written by leading experts in the field using a broad cellular and evolutionary framework, this highly readable volume offers a comprehensive examination of essential biological processes involved in the aging of man, animals, and plants. 400 pp., illus., 1978, $22.74/£11.94

Biomaterials
An Introduction
by **Joon Bu Park**

This volume elucidates the property–structure relations of man-made and natural implant materials, emphasizing the wound-healing process of soft and hard tissue replacements, and using numerous examples and problems for greater clarity. approx. 235 pp., illus., 1978, $27.00/£14.18

Making sense of man's universe

Garrett Hardin

The Little Universe of Man. By C. D. Darlington. Pp. 307. (George Allen and Unwin: London, 1978.) £6.95.

THIS is a biologist's attempt to make sense of the world's past, to foresee its probable future and, by putting foresight into words, possibly to influence what comes.

On what basis shall we appeal to people to alter their actions? "As the teachings of Adam Smith and Robert Malthus, Karl Marx and Charles Darwin agree, the animal principle of the self-interest of individuals, often, as we know, enlightened and extended, is the only motive to be infallibly relied on in the conduct of human affairs". It is psychologically necessary to believe in the rightness of one's action if that action is to be pursued with the fervour required to melt away opposition; out of this necessity springs the paradox of self-interest creating self-deception.

Does self-deception have survival value? It depends on the stage of ecological maturity of society. "'As the resources of the earth become more depleted and populations both more crowded and more deprived, the greater will be their effort to pass the problem on to the next generation. Self-deception will become more persuasive. Optimism will take hold. Those who remember 1914 and 1939 will also remember that these smaller calamities were produced by optimists but foreseen by pessimists. Indeed before these events an optimistic temperament had seemed to confer a permanent selective advantage in human evolution. It is not so now".

For the extreme example of an approach that will not solve the world's problems Darlington cites witchcraft: "The profession of witch-doctor dominates Negro life in Africa, creating a religion whose redeeming features we seek in vain". Despite justifiable criticisms that can be levelled against it the European approach to reality is the world's last and best hope: "The world is indepted to Europe for two great achievements which have transformed human life in the last 500 years. One is the control of nature which has led to our present crisis. The other is the understanding of nature and of man which is our means of escape from this crisis".

At every stage in our progress in understanding ourselves our will to self-deception erects taboos capable of delaying understanding for generations. In the English-speaking world the idea of man as an animal was under a taboo from about 1819 to 1859; human sexuality continued under taboo until about 1930; and the dispassionate discussion of the existence and consequences of innate human differences is still seldom possible. To a geneticist, of course, it is inconceivable that innate, heritable differences could not exist, and it is hard to believe that none of these is humanly important. A Darwinian biologist (and what other can there be?) looks for selection everywhere. Darlington's book is permeated with the Darwinian outlook. It takes only a moment for a perceptive biologist to postulate selective adaptations that may require years to validate. Darlington postulates many, so his book should stimulate many controversies.

The author is not unsympathetic to the currently reigning taboo: "Innate hereditary or genetic differences must not be admitted between individuals or groups, between classes or races, or even between the sexes. But above all what must not be discussed, what must be rejected, are differences in the foundations of human behaviour, the study of brains, of instincts, and of intelligence. These foundations are complex and happily concealed from the public view. They must remain concealed. In a world already overcrowded and over-troubled they might cause more trouble".

A great source of the ever-verdant controversy of nature versus nurture is the awkward fact of causal circularity, sometimes called the "Baldwin effect." First we select our inventions and then our inventions select us. Equestrian cultures undoubtedly selected for the ability to manage horses, which not all men have. Agriculture and the capital accumulation that it made possible selected for the willingness to engage in sustained, hard work and for a new form of competitiveness between tribes. The increase in the supply of food brought about by agriculture did not set supply and demand permanently in balance: it merely moved the instability to a higher population level and rewarded those who could successfully migrate into new and relatively unexploited environments. Language selected for those who could manipulate language—and their fellow-men—most competently. This fact justifies the overwhelming emphasis on language in intelligence tests; it also explains the passion invested in a particular language. "People have treated the survival of their language in speech and writing as a matter of life and death. And they have been right in doing so since language guarantees the survival of the breeding community".

Trying to make sense of the whole universe of man, as Darlington does, is an ambitious undertaking, scarcely mitigated by calling it a *Little Universe*. Every thoughtful person will find many points of disagreement with the author. The beauty of it is that the points of disagreement are easy to find, for Professor Darlington's exposition is crystal clear. The result is a splendid book for stimulating important discussions. ☐

Garrett Hardin is Professor Emeritus in the Department of Biological Sciences at the University of California at Santa Barbara.

Coral reef research

Coral Reefs: Research Methods. Edited by D. R. Stoddart and R. E. Johannes. Pp. 581. (UNESCO: Paris, 1978.)

THE study of coral reefs, earlier largely sustained by occasional expeditions, sprang suddenly into the fullest vigour in the Marshall Islands in 1945. This was in preparation for the atom bomb tests that began in the following year in Bikini and then Eniwetok atolls. Preliminary studies were exhaustive in their oceanographical and descriptive ecological content, and as a result of unprecedently deep boring, the validity of Darwin's postulates (if not their universal application) was established.

This impetus was sustained by the Coral Atoll Program of the Pacific

Science Board of the National Academy of Sciences of the USA with many of the results appearing in the *Atoll Research Bulletin* Important guidance was provided in the *Handbook of Atoll Research* published in 1953 by F. R. Fosberg and M.-H Sachet of the Smithsonian Institution who also edited the *Bulletin*.

Today the subject matter has proliferated widely. The mapping of reefs presents unique problems owing to geographical or seasonal inaccessibility and constantly changing pattern. New methods have developed for drilling, for determination of the sediments into which the reef mass disintegrates and for the local determination of sea level. Evaluation of a fauna and flora living on largely three-dimensional reefs with a territorial fish population presents problems not encountered in temperate seas.

In striking contrast to the surrounding oceanic deserts, atolls are oases of high productivity. But they are fragile systems without any sustaining reservoir of nutrients and phytoplankton, dependent on continuous re-cycling Everything removed, notably fish, affects total production. The influence of the algal zooxanthellae present in all hermatypic corals on both calcification and nutrition awaits final evaluation

Many working on these problems have devised new methods of attack, and new techniques such as aerial photography have appeared The whole subject has been critically reviewed by Working Group 35 of the Scientific Committee on Oceanic Research of UNESCO which is responsible for this volume with 43 contributions. These are grouped under Morphology and Structure, Biotic Distributions, and Energy and Nutrient Flux, their value the greater because the two first are edited by D R. Stoddart and the third by R E. Johannes, respectively the leading workers on the geomorphology and on the productivity of reefs

Both field workers and those more theoretically interested in the problems of coral reefs will find this book of the greatest help; it will also have permanent value as a record of the current state of enquiry.

C. M. Yonge

Sir Maurice Yonge is Honorary Fellow in the Department of Zoology, University of Edinburgh, UK.

Marine micropalaeontology

Introduction to Marine Micropaleontology. Edited by B. U. Haq and A. Boersma. Pp.376. (Elsevier: New York and Oxford, 1978.) $24.

It is fifteen years since the English translation of Pokorny's *Principles of Zoological Micropalaeontology* was published. Since that time there has been no new general text in micropalaeontology, despite the major contribution that the study of microfossils has continued to make in world exploration for oil and gas, and the successive achievements of the Deep Sea Drilling Project. It is perhaps not as well recognised as it ought to be that confirmation of the hypothesis of oceanfloor spreading and plate tectonics in the ocean basins is almost totally dependent on micropalaeontological evidence. Also the general application of 'absolute' ages to marine geological events is heavily dependent on the precision with which micropalaeontological biozones have been related to otherwise relatively isolated radiometric and palaeomagnetic determinations. Latterly too, in association with isotopic analysis, micropalaeontology has begun to yield significant new insights into the periodicity and chemistry of major oceanic changes that are themselves linked to worldwide variations in the planetary environment.

During this period of development knowledge of the various plant and animal microfossil groups has been vastly extended, new numerical methods introduced, and new technologies, such as scanning electron microscopy, adopted. Perhaps it is because of all this endeavour that no micropalaeontologists have had time to compile a review of the current state of their science. Here at last, however, Bilal Haq and Anne Boersma have persuaded a distinguished group of specialists to contribute to a pre-arranged pattern, a series of up-to-date accounts of the groups which they study. Thus, we have separate chapters on foraminifera, calcareous nannoplankton, ostracodes (by Pokorny himself), pteropods, calpionellids, calcareous algae and bryozoa—all mainly of calcareous composition; radiolaria, diatoms, silicoflagellates—all siliceous; and conodonts, dinoflagellates, spores and pollen and chitinozoa—of phosphatic and organic composition.

Each account gives an outline of the biology, taxonomy and stratigraphical distribution of the respective groups, but more interestingly usually goes on to consider their palaeoecology and contribution to palaeo-oceanic problem-solving They therefore serve at the same time the prosaic purpose of imparting technical information to the would-be specialist, and also stimulate an interest in problems of more general concern that can be approached by way of micropalaeontology. Naturally with so many different authors contributing the quality is sometimes variable, and, in spite of the extensive review system adopted, the text (be warned) does contain some unexpected errors Nevertheless the editors are generally to be commended on what they have achieved in terms of uniformity, quality and accuracy. The whole impact of the book is greatly helped by the generous use by all authors of a variety of types of line and half-tone diagrams and illustrations Here is a text that fully realises that endless prose is not always the best way of imparting information and understanding.

B. M. Funnell

B M Funnell is Professor of Environmental Sciences at the University of East Anglia, Norwich, UK

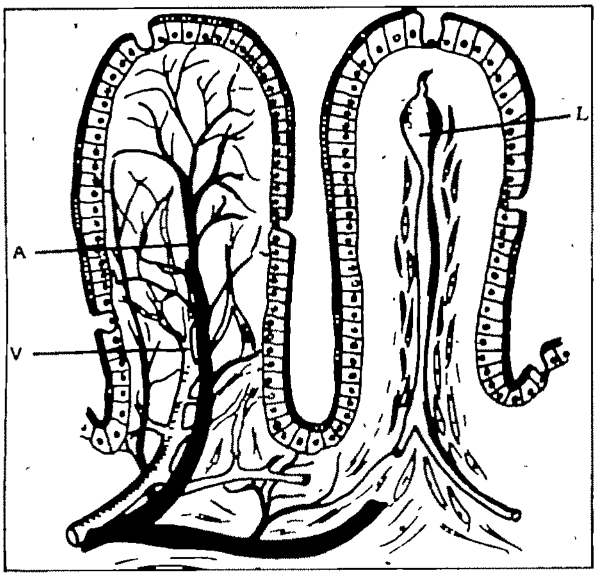
Chemistry and metabolism of vitamin D

Vitamin D Edited by D. E. M Lawson. Pp 433. (Academic: London, New York and San Francisco, 1978.) £20.50; $42 40.

Until the late 1960s vitamin D was generally regarded as being a subject of rather academic interest. It was acknowledged to play a role in intestinal calcium transport; and the main symptom of vitamin D-deficiency, a disorder of bone formation, was attributed not to a direct effect of the vitamin but to the secondary disturbance of calcium metabolism.

The past decade has seen dramatic advances in our understanding of the role of this vitamin. It would now be more appropriate to regard it not as a vitamin but as a metabolite and pro-precursor of a steroid-like hormone. The two hydroxylations, one in the liver and a subsequent one, controlled by parathyroid hormone, in the kidney convert the vitamin to an active form 1,25-dihydroxycholecalciferol. This latter compound acts on intestinal cell nuclei resulting in the induction of synthesis of proteins, including a calcium-binding protein, and leading to an increase in intestinal calcium transport, it is also the most potent stimulator of bone resorption yet discovered The clinical application of this information has been remarkably rapid Less than three years after the discovery of the role of the kidney in the intermediary metabolism of vitamin D an appropriate analogue had been synthesised and applied therapeutically by clinicians involved with the management of patients in chronic renal failure.

New books from CAMBRIDGE



The vessels of the intestinal villus. — Physiology of the Gastro-Intestinal Lymphatic System.

Physiology of the Gastro-Intestinal Lymphatic System

J. A. BARROWMAN

In this book the author provides a detailed treatment of the lymphatic system of the alimentary tract and its associated organs. He assesses the importance of the lymphatic drainage of the intestine, liver and pancreas in the normal physiological function of these organs This volume will be of particular interest to gastro-intestinal physiologists, biochemists, nutritionists and clinicians. **£17.50 net**

Monographs of the Physiological Society 33

Special Relativity

W. G. DIXON

The aim of this book is to show that by uniting dynamics, thermodynamics and electromagnetism into a coherent whole special relativity illuminates each of these subjects in a manner which cannot be obtained by studying them in isolation This analysis of special relativity is designed for advanced undergraduate students of physics and applied mathematics and research workers in related fields. **£14.50 net**

Introduction to the Theory of Thermal Neutron Scattering

G. L. SQUIRES

Thermal neutron scattering is a valuable tool for the study of the properties of solids and liquids. The present book provides an introduction to the basic quantum theory of thermal neutron scattering and applies the concepts to scattering by crystals, liquids and magnetic systems. Knowledge of physics to degree level is assumed The book is intended for experimenters rather than theoreticians. **£16.00 net**

The Microprocessor and its Application

Edited by D. ASPINALL

The microelectronics revolution has resulted in the manufacture of a large range of components which can be produced at low cost. In order to understand the properties and applications of each component, a sound knowledge of computer science and electronic engineering is required. Contributors to both disciplines collaborated to produce an advanced course at Swansea under the auspices of the EEC Technical Research Committee. This volume is based on material presented at the course and will be of interest to everyone involved in this new technology. **£12.50 net**

Reliable Knowledge

J. M. ZIMAN

In this book Professor Ziman explores the grounds for belief in science and in doing so soon escapes the conventional bounds of the philosophy of science to search for relevant evidence for his argument that scientific knowledge is no more than an elaborate extension of every-day reality. Well-known episodes in the natural sciences have shown that accepted scientific knowledge must always be treated with scepticism. In view of the importance of scientific ideas in modern culture this work should be of interest to every educated person. **£7.95 net**

First Paperback Edition

Models in Ecology

JOHN MAYNARD SMITH

This widely acclaimed book deals with ecological models of two kinds which illuminate one another: mathematical models of a strategic kind aimed at an understanding of the general properties of ecosystems, and laboratory models with the same aim in view. The author has taken great care to explain the mathematics he employs and the conclusions to be drawn, thus making this book attractive to those with a minimal familiarity with mathematical notation **£2.95 net**

Man and Nature in the Renaissance

A. G. DEBUS

This book provides an integrated introduction to science and medicine from the mid-fifteenth to the mid-seventeenth century. It describes the key developments that prepared the way for modern science in the late seventeenth century. The book is illustrated with many beautiful contemporary pictures and is suitable for undergraduates and general readers with an interest in this area.

Physicochemical Aspects of Protein Denaturation
by **S. Lapanje**, *University of Ljubljana, Yugoslavia.*
The material in this book has been selected and organised for readers of varying educational levels and professional backgrounds to give a concise and pragmatic review. Accounts of experimental methods are self-contained, with special emphasis given to the macromolecular properties of unfolded (denatured) proteins.
December 1978 — 344 pages
0471 03409 6 — $40.00/£19.50

Disposition of Toxic Drugs and Chemicals in Man: Vols 1 and 2
by **R.C. Baselt**, *Office of the Medical Examiner, State of Connecticut, and Dept. of Laboratory Medicine, University of Connecticut Health Center.*
The purpose of this two-volume work is to present in a convenient source the current essential information on the disposition of the chemicals and drugs most frequently encountered in episodes of human poisoning. The data included relate to the body fluid concentrations of substances in normal or therapeutic situations, concentrations in fluids and tissues in instances of toxicity and the known metabolic fate of these substances in man. Brief mention is made of specific analytical procedures which are applicable to the determination of each substance and its active metabolites in biological specimens. For convenience the substances have been grouped primarily by pharmacologic class and secondarily by chemical structure.
Volume 1: Centrally-Acting Drugs
September 1978 — 312 pages

Cell Survival After Low Doses of Radiation: Theoretical and Clinical Implications:
Proceedings of the 6th L.H. Gray Memorial Conference held at Bedford College, London, in September 1974.
edited by **Tikvah Alper.**
Reports and discussions of work on the initial shapes of cell survival curves are presented. Major topics included are the biological applications of statistical methods, the construction of mathematical models for cell survival, experimental and theoretical work on oxygen enhancement, fractionation and observations of tumours *in vitro* and *in vivo*.
November 1975 — 412 pages
0471 02513 5 — $35.50/£16.75
Published jointly by John Wiley and Sons Ltd, and the Institute of Physics.

Handbook of Clinical Ultrasound
edited by **M. deVlieger**, *Academic Hospital, Rotterdam.*
The first major work to cover thoroughly the scientific application of ultrasound in all medical specialties. It is composed of ninety-five chapters logically categorized into eight major specialty areas which are individually edited by internationally recognized specialists in their fields. It will provide the ultrasound professional with a sound basis for understanding this increasingly important diagnostic technique. Over 1,000 high-quality illustrations (photographs, scans, ultrasonic images, charts, tables, and diagrams) are included along with an extensive selection of references for further investigation.
December 1978 — 990 pages
0471 02744 8 — $85.00/£42.50

Medical Anthropology
by **G.M. Foster** and **Barbara G. Anderson**,
both of the University of California, Berkeley
A general survey of the field which examines similarities in health-related behaviour in both Western and the developing countries. A cross-cultural perspective emphasizing common elements of medical systems regardless of cultural context is stressed. The book provides comprehensive coverage drawing on pertinent medical sociology as well as anthropology. Also included are sociocultural factors in diet, a comprehensive discussion of medical institutions in the United States and a sophisticated, up-to-date presentation of ethnomedicine.
December 1978 — 368 pages
0471 04342 7 — $18.50/£9.75

Estrogens and Cancer
edited by **S.G. Silverberg** and **F.J. Major**, *both of the University of Colorado School of Medicine, Denver.*
This brings together with epidemiologic, clinical, and pathological data on the multi-faceted relationships between oestrogens and naturally occurring human neoplasms. It features the combined expertise of many eminent contributors, providing a multidisciplinary, one-volume source of current knowledge and future research directions regarding the often-controversial relationship between oestrogens and cancer.
December 1978 — 208 pages
0471 04172 6 — $30.00/£15.85

Non-Invasive Techniques in Cardiology: For the Nurse and Technician
by **A. Benchimol**, *Institute for Cardiovascular Diseases, Phoenix, Arizona*
A concise handbook for all those interested in the technical aspects of non-invasive diagnosis in cardiology. It presents basic guidelines for clinical application of the principles of ultrasound, with in-depth discussion of anatomy and physiology as well as specific disease states. More than 200 illustrations of phonocardiograms, pulse wave recordings, vectorcardiograms, and echocardiograms are included for increased understanding.
December 1978 — 336 pages

Circle No 15 on Reader Enquiry Card.

Despite the frenzy of research activity, particularly over the past five years, we still know remarkably little of the function of the numerous metabolites of vitamin D or their mode of action on target tissues. The complex interrelationship between vitamin D and the other calcium-regulating hormones and the diverse nature of the organs and tissues involved also emphasises the value of a multidisciplinary approach to the research This book is particularly valuable not only because it provides an excellent review of the current state of our knowledge of vitamin D but also because it serves as such a useful reference source of background information for researchers in various areas A number of the contributors to this volume are leaders of the research groups responsible for the major advances in vitamin D research and the various chapters therefore provide an authoritative and overall dogmatically balanced account of the literature and of current views on the many controversial aspects of vitamin D.

The chemistry and metabolism of the calciferols is reviewed in two chapters by Bell and by Holick and DeLuca respectively. Three subsequent chapters by Norman, Wasserman *et al.* and by Lawson consider the intestinal system from different aspects. One quarter of the entire text is devoted to two chapters on bone, by Aaron and by Barnes and Lawson, and a large proportion of these chapters consists of a review of the histology and biochemistry of growth cartilage and bone. Establishing the role of vitamin D in bone formation is clearly one of the main priorities for the next decade and the importance attached to the subject in this book is a reflection of this. The physiology and pathology of vitamin D in man is considered in two more chapters by Stanbury and Mawer, and in the final one Parsons discusses the relationship between it and other calcium-regulating hormones.

Most subjects are covered well but in such a forward-looking book I am surprised that the role of parathyroid and muscle as possible target tissues, and the control of intracellular calcium movement, were not considered in more detail. Overall though this is a valuable contribution to the literature and satisfies a very real need. It will be widely read and appreciated by the large numbers of biochemists, physiologists, nutritionists, clinicians and all others having an interest in calcium and phosphate metabolism

Centrifugation techniques

Centrifugation: A Practical Approach. Edited by D. Rickwood. Pp. 224. (Information Retrieval: London and Washington, 1978.) Hardback £8; $16; paperback £4; $9.

THE subject matter of this book justifies the publishers' claims that it is an introduction to the technique with an essentially practical basis. It discusses differential pelleting, rate zonal and isopycnic methods and their appropriateness for various purposes with different types of macromolecules, subcellular particles and cells. The operation of all types of rotor, including analytical, is described.

There are numerous suggestions for experiments that contribute to the understanding of principles. The comprehensive details provided embrace even the analytical methods to be used after centrifugation. Some of the warnings included imply that the recommended procedures have been modified in the light of experience. Apart from experiments that involve merely the generation or analysis of gradients, expensive equipment is involved. An unsupervised novice would therefore be well advised not to be too ambitious.

On the whole the authors are successful in choosing a happy medium between the risks of overloading the text with qualifying clauses and of presenting oversimplified statements. At some points the grammatical purist may wince, but there are few slips or printers' errors, although "Pedersen" is consistently spelt "Pederson". There is a useful glossary of terms, but symbols are not invariably standard throughout the book.
